REMOVING YEW TREES (*Croydon*).—You may very safely move a Yew, the stem of which is six inches in diameter, if you attend to the precautions we have repeatedly published.

SOFT EGGS (*Ibid.*).—We have often observed that these are usually the result of inflammation of some portion of the egg organs. Try a lower diet of boiled rice and mashed potatoes for a week or ten days. The excessive number of cocks, eight to thirteen pullets, should be entirely obviated; three cocks would be quite enough. If they are all together it is very erroneous practice.

CAMELLIA STOCKS (*S. W.*).—We cannot give you the information as to price. Write to two or three of the chief London nurserymen.

POULTRY PRIZES (*J. D.*).—If you directed your poultry not to be put up to sale, the committee have no right to deduct, from the amount of your prizes, the charge arising from their own mistake.

SEA-SHORE SEEDS (*B.*).—They were broken into small pieces by the post-office punch. You will find the recipe for the sulphur, soft-soap, and clay mixture, to dress your *Vines*, in almost every one of our past volumes. *Asparagus plants*, three years old, may be taken up very safely and replanted in the spring.

PYRENEAN MAIZE.—*R. W.* wishes to know where this can be obtained.

ZINC LABELS (*P.*).—Scour the face with rough sandpaper, and you will find that the ink will then adhere.

MANURING ROSES (*Ibid.*).—Put a mixture of your dungs, various, about six inches below the surface of the soil, over the roots, and in spring and summer give frequent waterings in a basin left in the soil. Answers to other queries next week.

NAMES OF PLANTS (*A Subscriber*).—1. *Asplenium Trichomanes*, the Maiden-hair Fern. 2. Appears to be seedling plants of some kind of *Aspidium*. 3. *Asplenium Ruta-Muraria*, the Wall-rose Spleen-wort. (A *New Subscriber*).—33. *Euonymus Europæus*, the common Spindle-tree or Frick-wood; and 33 is the white-fruited variety of the above, which is called *Euonymus Europæus*, var. *leucocarpus*.

CALENDAR FOR JANUARY.

ORCHID HOUSE.

AERIDES, Saccoboliums, Vandas, and such-like Indian plants, give water to once during the month. **AIR.**—In this first month of the year we frequently have severe frosty nights, and clear, bright, sunny days. The heat necessary to keep out the frost, and the bright sun, will raise the temperature of the house too high; to lower it to the

right pitch air must be given, and the apertures to give air ought to be so placed that the cold air does not rush in directly upon or through the plants. The best place for the openings is directly opposite the pipes; the air then becomes heated in a degree before it reaches the plants. **BLOCKS:** plants on these will require attention; any that are loose should be refastened; cleanse the leaves and pseudo-bulbs from green scurf and all kinds of insects. **CYATOPORIUMS,** see to; if any fresh growth is observable, repot in a rich compost. **DENUDORIUMS,** remove into a cool house; such as show growth may be potted and kept moderately moist. **HEAT:** keep both the houses to the lowest point of heat for the first half of the month; as the days lengthen allow the heat to increase a few degrees. **INSECTS,** continue to destroy. **MOISTURE:** on sunny days sprinkle the walks, walls, and pipes, two or three times a day. **PAIS GRANDIFLORAS,** now flowering, give plenty of water, and, if convenient, plunge the pots in a bed of heated leaves, or tanner's bark. **POTTING,** continue to perform upon all orchids beginning to grow. **SOILS,** procure, such as fibrous peat and turfy loam; lay them in a place to dry, to be ready for the general potting next month. **SOBRALIAS,** place in a cool house; heat 55° by day, and 50° by night; cut down all the shoots that flowered the preceding summer to allow room for the young shoots; keep them quite dry while at rest. **STANDOEAS** in baskets, if growing, dip in tepid water. **SYRINGE** blocks, as directed last month. **WATER** at the roots, apply carefully; do not wet the young shoots. **T. APPELBY.**

PLANT STOVE.

See last month. Prepare a hotbed, e., to strike *cuttings* in. **CLIMBERS** beginning to grow, tie in. **ERANTHEMUMS,** and other winter-flowering plants, give manure water to occasionally. Turn *tan-beds*, and renew the heat by adding fresh bark. **POT** a second batch of *Achimenes, Gesneras,* and *Glaxinias,* to succeed those done last month. Give moderate supplies of water till they begin to grow. The heat of this house must still be kept low, as too much excitement will, for want of light, cause the plants to grow weak, and the young leaves to come yellow. **SEEDS** of stove plants sow, e., giving only one watering till they begin to appear. **HARD-SHELLED SEEDS** steep in water heated to 180° or 200°; leave them till the water cools. **SPONGE** all large leaves, to clear off dust and insects. **SURFACE-STIA** the earth in pots, and clear off weeds and moss, and add a top-dressing of fresh compost. **T. APPELBY.**

FLORISTS' FLOWERS.

AIR. Whenever the sun overcomes the frost draw off the lights, it will refresh the plants much; if kept on the plants will begin to grow, and will be more liable to suffer from close covering during severe weather. In dull, humid, mild weather, give air at the back or sides by tilting up the lights. **ANEMONES** may yet be planted; choose a dry day for the purpose; cover the tubers with a thin layer of white sand. **AURICOLAS** and **POLYANTHUSES,** dress off decayed leaves; search for slugs in the frames and under the pots. **CARNATIONS** and **PICOTEES,** water when dry; pick off decayed leaves. Any leaves not decayed, but showing spots on them, remove; it is the plague of these plants. **CHRYSANTHEMUMS** now partially at rest, water once; any advanced shoots cut off, and make cuttings of; those out-of-doors place a slight covering of tanner's bark round, to protect them from frost. **CINERARIAS** will now be showing flower; water when dry; pot seedlings; repot young, small plants, struck late, to encourage growth. **CALCEOLARIA** seedlings, pot off from pans; repot young plants; give plenty of air; to smoke frequently, to destroy green fly; attend closely to watering, and avoid wetting the leaves; pick off daily all decayed leaves, and clear the surface of the soil of moss. These are, as the term is, *miffy* plants, and soon lost, without great care through this month. As the frost in this month is often very severe, apply COVERINGS of sufficient thickness to keep it out; light, open material, such as fern or straw, with a single mat over it to prevent it blowing about, is better than a covering of three mats laid close upon each other. **DALLIAS,** examine, and clear away all decayed tops or bulbs; any roots quite gone throw out at once. **FUCHSIAS:** as soon as shoots are made half-an-inch long, slip them off, and put them in sand under hand-glasses to strike; these early short cuttings, or slips, strike easily and quickly. **HOLLYHOCKS:** should the weather be open, plant them out; if not already done, the sooner this is done the better chance there is to have a good bloom. Use hoops and mats over the **TULIP** and **HYACINTH** nens in severe frosty or heavy rainy weather. **LOBELIAS** (Tall), keep from severe frost, and moderately dry. **PANSIES** in pots, look to, and water gently when dry; search frequently for slugs; those in the open air, in mild weather close the earth (loosened by frost) to the plants; if open weather, give a top-dressing of decayed leaves and a little soot. **PINKS:** after the frost is gone press the soil to the hand firmly, or they will be thrown quite out of the ground. **RANDOLPHUSES** may be planted, weather permitting, the last week in the month (see former number of *THE COTTAGE GARDENER* as to the manner); water, give none in frosty weather, but as soon as a change takes place, apply it early in the morning of a fine day. **VERBENAS,** give air to; trim off decaying leaves and mould; stop such as are growing and drawing up weak. **T. APPELBY.**

FLOWER-GARDEN.

ANNUALS in borders, keep free from fallen leaves or other litter; and, if the weather is fine, sow a few more at the end of the month. **BULBS,** see that mice or rats do not get to them: fresh soot keeps them off for awhile. **CUTTINGS,** of various hardy deciduous shrubs, climbing *Roses,* and the like, may yet be put in. **EDGINGS,** see that they are in good

order; slate edgings are, the best, then box: either may be laid this month. If the soil is dry at the end of the month, plant some *GLADIOLI*, such as *Psittacius*, *Gaudencius*, and their varieties, and continue in monthly succession to the end of April. Forget not to procure such *stakes, rods, pegs, and tallies*, as may be wanted next summer, in time. Destroy *rats, mice*, and other creatures destructive to seeds and roots. Again look at the protected plants, to see they are dry. GRASS, keep it clean and well rolled. HERBES, evergreen and otherwise, may yet be planted and dressed. LAYERS of evergreens, or deciduous shrubs, may be made as the borders are cleaned. MANURE, in composts, apply to such flower-beds as may require assistance; and in a solid, rotten state to all roses. MOLCH all newly-planted trees, &c. POTTED PLANTS in reserve garden secure from frosts. PLANTING, push forward in mild weather. PRIVET, make cuttings of the young shoots for increase. PRUNE and regulate every tree or bush which requires it; be more sparing with evergreens. RANUNCULUSES, if the soil be dry, plant a lot for another succession. ROSES, prune, plant, and dung, if not already done; protect *Tea* and young *Bourbons*; and wash them with strong lime and soot paint to kill moss and insects. SEROLINGS, and all young plants, protect according to their hardihood and strength. STUCKERS, pull up and destroy, unless wanted for increase, as those of some *Roses*, &c. TRENCH vacant ground. WALKS, roll as soon as they are dry, after rains or frost, and keep them regularly cleaned. WEEDS, destroy everywhere. WHEELING, reserve for frosty or very dry weather. Four times, within our memory, after unusual mild weather to the middle of January, we experienced severe frost and rough weather; provide against another of these trials in time, and see that everything is ready for securing a supply of ICE at the first opportunity. D. BEATON.

ORCHARD.

APPLES, cleanse from blight, moss, &c.; brine and soft soap are good for such purpose. BUSH-FRUIT, plant, prune. COMPOSTS, procure and prepare. CHERRIES, plant, prune. CUTTINGS, plant of Goosecherries. FRUIT-ROOM, look over weekly; be sparing in giving air; remove decaying fruit, and keep the room dark. FILBERTS, plant. FORK, borders. GOOSEBERRIES, plant, prune. LAYERS, make. LOAM, procure for stations. MULCHING, perform. MULBERRIES, plant. MEDLARS, plant. NAILS and Shreds, dress. NECTARINES: See *Peaches*. PLUMS, plant, prune. PEARS, plant; prune ordinary kinds. PEACHES, plant, prune, train, and dress. PLANTING in general proceed with. STATIONS, make. TRAINING in general proceed with. TRENCHING, carry on. TREES, stake. VINES, prune and train. WALNUTS, plant. WALL-TREES, in general, prune and regulate. WASH, the following, may be applied to walls: two-parts soot, two-parts sulphur, four-parts lime, applied with a bush into every crevice; urine or soap-suds, or both, may be employed to mix with. R. ERRINGTON.

FORCING-HOUSE.

AIR: See *Ventilation*. ASPARAGUS, get out succession-beds on mild heat. APRICOTS: See *Peach*. BOTTOM-HEATS, sustain and assist, 72° to 78°. CUCUMBERS, top, dress, train. CHERRIES: See *Peach*. COVERINGS, use where possible, to save fire-heat, and to protect from extremes. FIGS: See *Peach*. FIRES, use discreetly. GLASS, wash all roofs. GRAPES, ripe, use fires and air liberally, remove decaying berries. INSECTS, extirpate; use fumigation, the sponge, and soft soap. KIDNEY-BEANS, pot, and provide successions. NECTARINES and *Peaches*, in bloom, air liberally, and shake to disperse the pollen. MUSHROOMS, protect well, if out doors; in house, use much water on floors. PINES, continue to sustain proper heat to, cover well in dung-pits, and remove linings. PEACHES: See *Nectarines*. ROOFS, protect in boxes, tubs, &c. STRAWBERRIES, give air and light, use liquid-manure where blossoming; introduce successions. TARRAGON and other herbs, introduce to heat. VENTILATE as freely as you dare. VINEY (Early), proceed steadily; keep a moist air; raise the heat at blooming-time; use sulphur against mildew. WATER, always use in a tepid state. R. ERRINGTON.

GREENHOUSE.

AIR, admit at every favourable opportunity, whenever the temperature outside is above 35°, except in windy or foggy weather, especially among Heaths, Epacris, and Azaleas that you do not wish to bloom early. In foggy weather, though warm, it will be advisable to put on a little fire, to change the visible to invisible vapour. If the fog was of short continuance, and could be kept out of the house, air might be dispensed with, as well as fires, though it should not be forgotten that the motion given to the air by a little firing is a great security for the health of the plants in dull weather. Soft-wooded plants should be kept at one end of the house. BULBS and hardy SUCCULS, such as Lilacs, Azaleas, and Roses, introduce from the forcing-house, placing them at the closest and warmest end of the house; Calceolarias, Cinerarias, Geraniums, and Chinese Primroses, clean, shift, and supply at times with manure-water. CAMELLIAS and CYTISUSES opening their buds, supply with manure-water. CLIMBERS, prune in, if not already done, those that produce their flowers on the young wood; others, such as *Kennedys*, now flowering and growing, attend to; and especially train, every day, the *Tropaeolums*, if you wish to prevent confusion. No time should be lost in potting such kinds as *Tricolorum*, *Juruttii*, *Speciosa*, *Azura*, &c., if not already done. FIRES, light in close, dull weather, to enable you to give a circulation of air. Beware of heating too much when frosty, as, without due precaution, the atmosphere will be too dry; it is better to use coverings for the glass. FUCHSIAS: the forwardest may now

be pruned and repotted. GERANIUMS and CINERARIAS will, in all likelihood, want cleaning and liming. The first may now be repotted for late May and early June blooming, and the latter must be shifted and kept growing, so as to prevent them throwing up flower-stalks, if late bloom and large specimens are desired. Where room is limited, a fine display is obtained by successions, and using not larger than six-inch pots. Not a withered leaf, nor an *aphis*, should stand longer than when seen. When the fly covers a leaf in myriads, smoking with tobacco then is tantamount to labour and money thrown away. ROSES in pots, for April and May and June blooming, in the greenhouse, finish pruning; wash with a pint of soot, sulphur, and clay; top-dress with rich compost; and plunge, if possible, in a house or pit—sawdust will be a good material—and give at first a temperature of 40° to 45° at night, and from 45° to 55° during the day. STUCCULENTS, unless growing and showing flower, refrain from watering. *Tropeolum Lobbianum*, and *Manettia bicolor*, will be great ornaments now, in a warmish dry greenhouse. WATER plants only when requisite, and perform the operation after breakfast, using water rather higher than the medium temperature of the house. Place a few Achimenes, Gesnera, and Gloxinia roots into heat for early blooming. In a conservatory or greenhouse, where no hard-wooded plants to speak of are grown, and where a medium heat of 50° can be maintained—that is, 45° at night, and 55° during the day—*Poinsettia pulcherrima*, *Euphorbia Jacquiniflora*, &c., may be introduced from the stove. For the *Poinsettia* especially, if a little extra heat can be given in April, a close cold pit in summer, an average night temperature of 50° in October, and a medium of from 45° to 55° in winter, nothing can surpass the brilliancy of the large crimson floral leaves, for a couple of months, at this period, while the brilliancy remains longer in such a house than in a plant stove. (See *Calendar of last month*.) R. FISHER.

KITCHEN-GARDEN.

ARTICHOKEs, attend to, shelter, &c. ASPARAGUS, plant in hotbed; attend to that forcing; temperature about 65°, and at night 50°. BEANS, plant, b.; earth-stir among often; advancing crops protect from frost; plant in hotbed, if required. BEET (red), plant for seed. BROCOLI, protect from frost. CABBAGES, plant, e.; sow, e.; plant for seed. CANNONS, attend to, shelter, &c. CARROTS, sow small crop; plant for seed; (early Horn) sow on gentle hotbeds, fill the frame up well with earth, so as to bring the crop up close to the glass; attend to early thinning-out, and earth-stirring with a little pointed stick among all frame crops. CAULIFLOWERS in frames, attend to protection from frost, and give all open air possible in open weather, by taking the lights entirely off; also, hand-glass crops, clear away all decayed leaves and slugs, and earth-stir often; if young plants are required, a pinch of seed may be sown in pans, and placed in any heated structure, but have a gentle hotbed made up ready to prick them out upon, keeping the young crop up close to the glass. CELERY, earth up, shelter, &c. COMPOSTS, prepare and turn over. CUCUMBERS, sow and prick out; temperature, by day, 70° to 75°, and at night 65°. DUNG, for hotbeds, prepare in earnest; wheel on to vacant ground. EARTH for hotbeds, prepare. EARTH-STIR, and fasten plants disturbed by frost, &c. ENRIVE, blanch, protect. FROST, protect plants from, by temporary covering. GROUND, trench vacant. HORSE-RADISH, plant at any time during the month in open weather. HOTBEDS, make and attend to. JERUSALEM ARTICHOKEs, take up and replant in open weather, at any time during the month. KIDNEY-BEANS, sow in succession in hotbed, &c. KALE (Sea), attend to; force in succession. LETTUCES, in frames, attend; protect from frost; sow on warm border, e. LIQUORICE, plant, e., and dig up three-year-old. MELONS, sow, for fruiting in May; day temperature 75°, night 65°. MINT, force, in hotbed. MUSHROOM BEDS, make, and attend to those producing; procure horse-droppings for. MUSTARD and CRESS, sow in hotbed. ONIONS, clear from weeds; examine stored; sow a small crop, e.; plant for seed. PARSLEY, sow, e.; protect from frost. PARSNIPS, plant for seed. PEAS, protect from birds by straining a single string of worsted along over the row; attend to the early pea sowing as near the first of the month as possible. It is a good maxim to always have a mouse trap or two set about the pea quarters. Sow; earth-stir; shelter from frost; and prepare stick. This is a good season for making main sowings of early and second early peas where the soil works well and the weather is open. POTATOES, plant in slight hotbed; and they may also be planted out in the open border, or quarters, in fine open weather, where the soil works well. Examine those in the store. RAISHES, sow, in hotbed; thin out as soon as the plants can be handled and sift a little dry earth among them; sow in border, e. RAPE (for salading), sow in hotbed; (edible-rooted), sow. RHUARB, attend to; force, either in pots, to be planted in some heated structure, or covered up with pots or tubs and fermenting materials. SALADING (Small), sow. SAVOYS, plant for seed. SPINACH, keep clear from weeds and fallen leaves; make a small sowing towards the end of the month. TANSKY, plant in hotbed. TARRAGON, plant in hotbed. TURNIPS, plant for seed; should the weather seem inclined to set in severe, store in a good supply, or heap them to cover them over with coal-ashes. WEEGOS, continually destroy, and do any work which will lessen that of the following busier months; in particular, such as planting all the main out-door crops of *Potatoes*, wherever the soil will allow of it, and the weather is favourable. WONNICE, destroy in the mushroom-house by trapping under dry hay, and scalding it in hot-water; or by baiting small pots with boiled potatoes, or slices of potatoes under dry moss. T. WEAVER.

METEOLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-six years, the average highest and lowest temperatures of these days are 40.7° and 30.3° respectively. The greatest heat, 54°, occurred on the 6th in 1845; and the lowest cold, 6°, on the 7th in 1841. During the period 119 days were fine, and on 70 rain fell.

BRITISH WILD FLOWERS.

(Continued from page 273.)

ARABIS CILIATA: Fringed Wall Cress.

Description.—It is a biennial. Root simple, tapering.

Stem generally solitary, from two to four inches, but, when cultivated, near a foot in height, erect, quite simple, leafy, cylindrical, smooth. Root-leaves several, in one simple tuft, various in size, reversed-egg-shaped, often reddish; tapering at the base; those of the stem alternate, stalkless, or half-clasping, elliptic-oblong; all somewhat milky-green, quite smooth on both sides, more or less evidently toothed, fringed with simple or forked, scattered, spreading, bristly hairs; some of which are often crowded into a small tuft or beard at the tips of the leaves, whilst others form a more regular fringe upon the taper bases, or foot-stalks, of the root-leaves. Flowers in a simple, terminal, upright, smooth, flat cluster. Calyx tawny, with a white edge. Petals twice its length, pure white, almost erect. Pods upright, slender, each tipped with the simple, blunt, stigma, supported by a very short, conical style; their valves undulated, channeled, and slightly keeled.

Places where found.—It is very rare, being found only on rocks by the sea-side at Rinville, Cunnamara, in the west of Ireland; and in Scotland on rocks near Loch Lea, in Glen Esk.

Times of flowering.—July and August.

History.—This is the *Turritis ciliata*, and *T. alpina*, the Fringed or Alpine Tower Mustard, of some botanists. The specific name *ciliata*, eye-lashed or fringed, alludes to the hairs round the edges of the leaves. (Smith. *Withering.*)

THERE was a time, part of what some people still call "the good old times," a time enduring to the close of the reign of George III., when Kew Gardens were sealed up from vulgar eyes, and its vegetable riches guarded as watchfully, and kept as exclusive, as the golden fruit of the Hesperides. In those times, the heart that beat beneath a fustian jacket was considered as incapable, or as unworthy, of being gladdened by the beautiful in nature; and the head that was ever put into a brown paper cap was deemed as too devoid of taste and ingenuity ever to relish or succeed in the culture of exotic plants. If the hands connected with such heads and hearts should be allowed to come within arms length of such plants, there was no telling what might happen. The least horrible event expected to occur was that they would tear off the leaves and blossoms for the mere sake of mischief, and from the mere propensity to destroy what is lovely. So Sir Joseph Banks, and others of those "old times," shut up Kew Gardens, and were sedulous and diligent to take care that when once a

plant got within their iron gates no mortal out of the peerage, and very few in it, should have a cutting or a root whereby it might be propagated.

It never entered among the thoughts of those guardians of the Kew riches that it was possible, or proper, that such things should be diffused among the people, known to them only as "the vulgar." They never seem to have suspected that by such diffusion—by fostering a taste for such things—by rendering a man's garden more varied and beautiful, his dwelling more attractive—that you weaned him from pleasures not of home-growth, and elevated his desires to strive for something less debasing than such things as could be found on and around the tap-room table.

In these "bad times" of change we go upon a different system—we have adopted as a rule, that the more people have of new plants, and the more they delight in them, the happier and the better they will be; we let them into Kew Gardens unwatched, yet not a leaf is rifled; we build, or they build for themselves, Crystal Palaces,

and we make for them parks and gardens, where they may walk unrestrained, and roll upon the grass even, and bask in the sunshine, and revel in pure air. And what is the consequence of all this? We must condense the reply into one sentence—We have had no Revolution.

If we were to search through the entire "Encyclopædia of Plants" for a single species that would illustrate best the working of the two systems, we should find none that would afford that illustration so forcibly as THE FUCHSIA.

Who is there among the thousands who will read this page that would not grieve if this plant of the garden, the window-sill, and the conservatory, was totally destroyed? Who would not feel that they who nursed it either in a cracked tea-pot, or in an Etruscan vase, had to suffer a lost pleasure? Yet this gay little friend of the poor as well as of the rich, would never have been gladdening them if it could have been found nowhere than in Kew Gardens as managed under the old system. It was introduced into those gardens by a Captain Firth, as far back as 1788, and there it remained when a second edition of the *Hortus Kewensis* was published in 1811. It was a close prisoner; it had not escaped to brighten up a cottager's window, much less had any one endeavoured to raise from it varieties; like all other things *then* at Kew, it was a forcible illustration of the hidden talent—it was useless even to the possessor.

Now, we know, and are rejoicing in the knowledge, that a hundred of its varieties are adorning our houses and gardens. This has all happened since 1815, and how it happened, how the Fuchsia got among the people, is well told in this narrative.*

"Soft Midsummer air, cheery with sunshine and perfumed with all the scents that it had robbed out of his nursery garden, crept in through the monthly roses at the porch and the half open cottage door, to make itself at home in George Swayne's room. It busied itself there, sweeping and rustling about, as if it had as much right to the place and was as much the tenant of it as the gardener himself. It had also a sort of feminine and wifely claim on George; who, having been spending half an hour over a short letter written upon a large sheet, was invited by the midsummer air to look after his garden.—The best efforts were being made by his gentle friend to tear the paper from his hand. A bee had come into the room—George kept bees—and had been hovering about the letter; so drunk, possibly, with honey that he had mistaken it for a great lily. Certainly he did at last settle upon it. The lily was a legal document to this effect:—

"SIR.—We are hereby instructed to give you notice of the death of Mr. Thomas Queeks, of Edmonton, the last of the three lives for which your lease was granted, and to inform you that you may obtain a renewal of the same on the payment of one hundred guineas to the undersigned. We are, Sir,

"Your (here the bee sat upon the obedient servants),

"FLINT AND GRISTON."

"Mr. Swayne granted himself a rite to consider in his own mind what the lawyers meant by their uncertain phraseology. It did not mean, he concluded, that Messrs. F. and G. were willing, for one hundred pounds, to renew the life of Mr. Queeks, of Edmonton; but it did mean that he must turn out of the house and grounds (which had been Swayne's Nursery Garden for three generations past) unless he would pay a large fine for the renewal of his lease. He was but a young fellow of five-and-twenty; who, until recently, had

been at work for the support of an old father and mother. His mother had been dead a twelvemonth last Midsummer-day; and his father, who had been well while his dame was with him, sickened when she was gone, and died before apple-gathering was over. The cottage and the garden were more precious to George as a home than a place of business. There were thoughts of parting—like thoughts of another loss by death, or of all past losses again to be suffered freshly and together—which so clouded the eyes of Mr. Swayne, that at last he could scarcely tell when he looked at the letter whether the bee was or was not a portion of the writing.

"An old woman came in with a Midsummer cough, sounding as hollow as an empty coffin. She was a poor crone who came to do for George small services as a domestic for an hour or two every day; for he lighted his own fires, and served up to himself in the first style of cottage cookery his own fat bacon and potatoes.

"I shall be out for three hours, Milly," said George, and he put on his best clothes, and went into the sunshine. 'I can do nothing better,' he thought, 'than go and see the lawyers.'

"They lived in the City; George lived at the east end of London, in a part now covered with very dirty streets; but then covered with copse and field, and by Swayne's old-fashioned nursery ground, then crowded with stocks and wallflowers, lupins, and sweet peas, pinks, lavender, heartsease, boy's-love, old man, and old-fashioned plants; for it contained nothing so tremendous as *Schizanthus*, *Escallonia*, or *Clark's pulchellus*, which were weedy little atomies, though they sound enough to rival any tree on Lebanon. George was an old-fashioned gardener in an old-fashioned time; for we have here to do with events which occurred in the middle of the reign of George the Third. George then—I mean George Swayne, not Georgius Rex—marched off to see the lawyers, who lived in a dark court in the City. He found their clerk in the front office, with a marigold in one of his button-holes; but there was nothing else that looked like summer in the place. It smelt like a monthly shut up tool-house; and there was parchment enough in it to make scarecrows for all the gardens in Kent, Middlesex, and Surrey.

"George saw the junior partner, Mr. Griston, who told him, when he heard his business, that it was in Mr. Flint's department. When he was shown into Mr. Flint's room, Mr. Flint could only repeat the instructions of the landlord.

"You see, my lad," he said, "these holdings that have been let hitherto for thirty pounds per annum are now worth fifty. Yet my client, Mr. Crote, is ready to renew the lease for three more lives at the very slight fine we have named to you. What would you have more reasonable?"

"Sir, I make no complaint," George answered; "only I want to abide by the ground, and I have not so much money as you require. I owe nobody a penny; and to pay my way and lay by enough money for next year's seeds and roots, has been the most that I can manage. I have saved fifteen pounds. Here it is, Sir; take it, if it will help me in this business."

"Well," Mr. Flint suggested, "what do you say to this? I make no promise, but I think I can persuade Mr. Crote to let you retain possession of your land, for—shall we say?—two years, at the rent of fifty pounds; and at the expiration of that term, you may perhaps be able to pay the fine and to renew your lease."

"I will accept that offer, Sir." A homespun man clings to the walls of home. Swayne's nursery would not support so high a rental; but let the future take thought for itself—to postpone for two years the doom to quit the roof-tree under which his mother suckled him was enough for George.

"So he turned homeward and went cheerfully on his way by a short cut through narrow streets and lanes that bordered on the Thames. His gardener's eye discovered all the lonely little pots of mignonette in the upper windows of the tottering old houses; and, in the trimmer streets, where there were rows of little houses in all shades of white-wash, some quiet fresh looking, inhabited by people who kept their windows clean, he sometimes saw as many as four flower-pots upon the window sill. Then there were the squares of turf, put, in weekly instalments of six inches, to the credit

* This narrative is substantially true; we believe it has been published in some popular work, but it was sent to us as an extract from an Irish newspaper.

of caged larks, for the slow liquidation of the debt of green fields due to them. There were also parrots; for a large number of the houses in those river streets were tenanted by sailors who brought birds from abroad. There were also all sorts of grotesque shells; and one house that receded from its neighbours had a small garden in front, which was sown over with shells instead of flowers. The walks were bordered with shells instead of boxwood, and there were benches upon the wall instead of wall-flowers. The summer-house was a grotto; but the great centre ornament was a large figure-head, at the foot of which there was a bench erected, so that the owner sat under its shadow. It represented a man with a great beard, holding over his shoulder a large three-pronged fork; which George believed to be meant for Neptune. That was a poor garden, thought George; for it never waved nor rustled, and did not by one change of feature—except that it grew daily dirtier—show itself conscious of the passage of the hours and days, and months and seasons.

“I interested George a great deal more to notice here and there the dirty leaves of new kinds of plants; which, brought home among the sailors, struggled to grow from seed or root. Through the window of one house that was very poor, but very neat and clean, he saw put upon a table to catch the rays of summer sun, a strange plant in blossom. It had a reddish stalk, small-pointed leaves; and from every cluster of leaves hung elegant red flower-bells with purple tongues. That plant excited him greatly; and, when he stooped to look in at it, he felt some such emotion as might stir an artist who should see a work by Rubens hung up in a pawnbroker's shoe window. He knocked at the green door, and a pale-faced girl opened it, holding in one hand a piece of unfinished needlework. Her paleness left her for a minute when she saw it was a stranger who had knocked. Her blue eyes made George glance away from them before he had finished his respectful inquiry. ‘I beg your pardon,’ he said, ‘but may I ask the name of the flower in the window, and where it came from?’

“‘Will you walk in, if you please, sir,’ said the girl, ‘mother will tell you all she knows about it.’

“With two steps the young gardener strode into the small front room where a sick and feeble woman sat in an arm chair. The room was clean and little furnished. There was only sand upon the floor; and, on the table with some more of the girl's work, was part of a stale loaf, flanked with two mugs that contained some exceedingly blue and limpid milk. George apologised for his intrusion; but said what his calling was, and pleaded in excuse the great beauty and novelty of the plant that had attracted him.

“‘Ay, ay, but I prize it for more than that,’ said Mrs. Ellis, ‘it was brought to me by my son. He took it as a cutting, and he brought it a long way, dear fellow, all the way from the West Indies, nursing it for me. Often he let his own lips perch, sir, on the voyage, that he might give water enough to the flower that he took home for his mother. He is a tender-hearted boy, my Harry.’

“‘He is young, then?’

“‘Well, he is not exactly a boy, sir; but they are all boys on board ship, you understand. He could carry off the house upon his back, Harry could; he is so wonderful broad-chested. He's just gone a long voyage, sir, and I'm afraid I shall be gone a longer before he comes back; and he said when he went, ‘Take care of the plant, mother, it'll have hundreds of bells to ring when I come back to you next year.’ He is always full of his fun, sir, is my Harry.’

“‘Then ma'am,’ George stammered, ‘it is a plant you wouldn't like to part with.’

“The poor woman looked angry for a moment; and then, after a pause, answered gently, ‘No, sir, not until after my time comes.’

“The young gardener, who ought to have gone away, still bent over the flower. The plant was very beautiful, and evidently stood the climate well, and it was of a kind to propagate by slips. George did not well know what to say or do. The girl who had been nimbly stitching, ceased from work and looked up wonderingly at the stranger, who had nothing more to say, and yet remained with them. At last, the young man, with the colour of the flower on his cheeks, said, ‘I'm a poor man, ma'am, and not much taught. If I'm going to say anything unbecoming, I hope

you'll forgive it; but if you could—if you could bring your heart to part with this plant, I would give you ten guineas for it, and the first good cutting I raise shall be yours.’

“The girl looked up in great astonishment, ‘Ten guineas!’ she cried, ‘why, mother, ten guineas would make you comfortable for the whole winter. How glad Harry will be!’

“The poor old woman trembled nervously; ‘Harry told me to keep it for his sake,’ she whispered to her daughter, who bent fondly over her.

“‘Does Harry love a flower better than your health and comfort?’ plead Harry's sister.

“A long debate was carried on in low tones, while George Swayne endeavoured to look as though he were a hundred miles off, listening to nothing. But the loving accents of the girl, debating with her mother tenderly, caused Mr. Swayne—a stout and true-hearted young fellow of twenty-five—to feel that there were certainly some new thoughts and sensations working in him. He considered it important to discover from her mother's manner of addressing her that the name of the young woman was Susan. When the old lady at last consented with a wish to George's offer, he placed ten guineas on the table beside the needlework, and only stole one glance at Susan, as he bade good-bye, and took the flower-pot away, promising again earnestly that he would bring back to them the first good cutting that took root.

“George Swayne, then, having the lawyers almost put out of his head, carried the plant home and duly busied himself in his greenhouse, over the multiplication of his treasure. Months went by, during which the young gardener worked hard and eat sparingly. He had left to himself but five pounds for the general maintenance of his garden; more was needed, and that he had to pinch, as far as he dared, out of his humble food and other necessaries of existence. He had, however, nothing to regret. The cuttings of the flower-bells thrived, and the thought of Susan was better to him than roast-beef. He did not again visit the widow's house. He had no right to go there, until he went to redeem his promise.

“A year went by: and when next July came George Swayne's garden and greenhouses were in the best condition. The new plant had multiplied by slips, and had thriven more than he could have expected. The best plant was set by until it should have reached the utmost perfection of blossoms to be carried in redemption of the promise made to widow Ellis. In some vague way, too, Mr. Swayne now and then pondered whether the bells it was to set ringing after Harry had returned might not be after all the bells of Stepney parish-church.—And Susan Swayne did sound well, that was certain. Not that he thought of marrying the pale girl, whose blue eyes he had only seen, and whose soft voice he had only heard once; but he was a young fellow and he thought about her, and young fellows have their fancies, which do now and then shoot in unaccountable directions.

“A desired event had happened one morning. The best customer of Swayne's nursery grounds, the wife of a city knight, Lady Salter, who had a fine seat in the neighbourhood, alighted from her carriage at the garden gate. She had come to buy flowers for the decorations of her annual grand summer party; and George, with much perturbation, ushered her into his greenhouse, which was glowing with the crimson and purple blossoms of his new plant. When Lady Salter had her admiration duly heightened by the information that there were no other plants in the country like them; that, in fact, Mr. Swayne's new flowers were unique, she instantly bought two slips at a guinea each, and took them home in triumph. Of course, the flower-bells attracted the attention of her guests, and of course, she was very proud to draw the attention to them. The result was that the carriages of the great people of the neighbourhood so clogged up the road at Swayne's nursery, day after day, that there was no getting by them. George sold for a guinea each all the slips he had potted, keeping only the continuance of his trade, and carefully reserving his finest specimen. That in due time he took to Harry's mother.

“The ten guineas, added to the produce of Susan's labour—she had not slacked it a jot—had maintained the sickly woman through the winter; and, when there came to her a letter, one morning in July, in Harry's dear scrawl, posted from Portsmouth, she was half restored to health. He would be with them in a day or two, he said. The two

women listened in a feverish state of excitement for every knock at the green door. Next day a knock came: but it was not Harry—Susan again opened to George Swayne. He had brought their flower-bells back; and, apparently, handsomer than ever. He was very much abashed, and stammered something; and when he came in, he could find nothing to say. The handsome china vase, which he had substituted for the widow's flower-pot, said something, however, for him. The widow and her daughter greeted him with hearty smiles and thanks; but he had something else to do than to return them—something of which he seemed to be exceedingly ashamed. At last he did it. 'I mean no offence,' he said, 'but this is much more yours than mine.' He laid upon the table twenty guineas. They refused the money with surprise; Susan with eagerness. He told them his story; how the plant had saved him from the chance of being turned out of his home; how he was making money by the flower, and how fairly he considered half the profits to be due to its real owner. Thereupon the three became fast friends, and began to quarrel. While they were quarrelling there was a bouncing knock at the door. Mother and daughter hurried to the door; but Susan stood aside that Harry might go first into her mother's arms. "There's a fine chime of bells," said Harry, looking at his plant, after a few minutes. 'Why it looks no handsomer in the West Indies.—But where ever did you get that splendid pot?'

"George was immediately introduced. The whole story was told, and Harry was made a referee upon the twenty-guinea question.

"God bless you, Mr. Swayne," said Harry, 'keep that money if we are to be friends. Give us your hand, my boy; and mother, let us have something to eat.' They made a little festival on that evening in the widow's house, and George thought more than ever of the chiming of the bells as Susan laid her needlework aside to bustle to and fro. Harry had tales to tell over his pipe; and I tell you what, Swayne,' said he, 'I'm glad you are the better for my love of rooting. If I warn't a sailor myself I'd be a gardener. I've a small cargo of roots and seeds in my box that I brought home for mother to try what she can do with. My opinion is that you're the man to turn 'em to account; and so, mate, you shall have 'em. If you get a lucky penny out of any one among 'em, you're welcome; for it's more than we can do.'

"How these poor folk laboured to be liberal towards each other; how Harry amused himself on holidays before his next ship sailed with rake and spade about his friend's nursery; how George Swayne spent summer and autumn evenings in the little parlour; how there was really and truly a chime rung from Stepany steeple to give joy to a little needle woman's heart; how Susan Swayne became much rosier than Susan Ellis had been; how luxuriously George's bees were fed upon new dainties; how Flint and Gristone conveyed the nursery-ground to Mr. Swayne in freehold to him and his heirs for ever, in consideration of the whole purchase-money which Swayne had accumulated; how the old house was enlarged; how a year or two after that, Susan Swayne, the lesser, dug with a small wooden spade side by side with giant Uncle Harry; who was a man to find the centre of the earth under Swayne's garden when he came home ever and anon from beyond the sea, always with roots and seeds, his home being Swayne's nursery, and, finally, how happy and how populous a home the house in Swayne's nursery grew to be—these are results connecting pleasant thoughts with the true story of the earliest cultivation in this country of the flower known as the *Fuchsia*."

Few irremediable causes of premature decay actually exist in nature; the inconsiderate or wilful misuse of the very means of preserving health proving not unfrequently a cause of death. In these matters we partly depend upon our own conduct, whether as individuals, or socially, or as a nation.* Modern science and phi-

* Chlorine, the efficient disinfecting agent of chloride of zinc, is the acting principle also in chloride of sodium, or sea-salt, the typical purifier. The spread of cholera in the East Indies must have been greatly favoured by the laws which restrict the use of salt; possibly this may have been one exciting cause.

lanthropy can only point out similar means of safety to those originally enjoined on the Israelites, if to these precepts be added the duty of kindness to the poor, and that enlarged sphere of humanity which regards every man as our neighbour, there is absolutely nothing left to be added to what has been inculcated by the good physician. If men could but be induced to live as they ought to live (instead of doing what they ought not, and leaving undone what they ought to do), there seem grounds for concluding that the average term of human life might be greatly increased, and the amount of human suffering lessened. On this point there is a marvellous agreement between the abstract speculations of cool calculating rationalists, and the transcendental opinions of the religious.

We have already seen in the case of the Jews how beneficial has been the mere keeping clean the outside of the cup, so far as bodily health is concerned. In those worn-out Oriental countries, where a long course of misuse has rendered the banks of rivers, &c., deadly to the European constitution, a Hindoo or Mahometan population yet contrives to live with few hereditary ailments, retaining much patriarchal simplicity of manners, and most of the old ceremonial instructions, though the spirituality which these once typified is rejected, and the moral and intellectual condition is deplorable enough.

The members of the Society of Friends are noted for their longevity; their general prosperity; and their puritanic adherence to Bible rules of life. The same may be affirmed of ministers of religion as a body. The old monks (considering the times in which they lived) were distinguished from those about them by a greater attention to religious duties; and also by their greater intellectual attainments, their more successful cultivation of the soil, and their consequent health and wealth. Their fall was a consequence of their misuse of these earthly blessings. They waxed fat, and kicked; as we are all too apt to do. Here has ever been and still is the great danger.

Contrasting the state of things in the North of Ireland with the poor Bible-less South (where a settler recently said, "If I could only make these men Mahometans it would be a step gained") we shall find physical destitution closely connected with religious destitution. This is not the place to enter on the old liberties of the Gallican, suffice it to say that the Bible is not forbidden in France. Cuvier was a Bible-society man. Well, in this country, and in France, people live one-fourth longer than in such places as dark Austria or sordid Russia. We have an unwilling evidence, in the profane sneers of the scoffer at the worldly success of saintly folk, that godliness is gain, even in this life.

Contemporary historians have chronicled violences, wars, frauds, persecutions, and the like, because they have been extraordinary exceptions to the even current of events, and have arrested attention at the time. The normal tendency of what is right, virtuous, true, and of good report to work its own reward, in every age has been unnoted, except incidentally. Modern research

has been more directed towards collating these scattered incidental allusions; and the result has been to give us quite a new notion of the every day life of times too hastily considered days of violence and blood only.

A gay Parisian about to settle in life, as we say, consulted a leading French doctor, having reason to dread hereditary consumption, a disease which carries off one-fourth of the people of Paris. "Never fear," was the reply, "spend six or eight months in the year in the country, and lead a patriarchal life when you are there."* This is the great secret. We cannot "lay in a stock of health" during a hurried excursion from one luxurious hotel to another. A lodging at a fashionable watering place is not much better. "Talk about *rus in urbe*," once observed a classical friend of ours, "I call this *urbe in rus*!" If the country is to restore us, we ought to catch somewhat of the sweet infection of its every-day life. A country cottage-home, the care of the domestic animals, the garden and kindred avocations, besides bringing us out to enjoy the fresh air, are of themselves eminently healthful. Besides, we contend that they afford the means of studying the very laws of life, just as comparative anatomy has elucidated the secret of the whole human frame. And we think they enable us the more aptly to comprehend the significance of many of the deep sayings of old.

We cannot accept without protest the dogma of the day—that civilized man should be perpetually inventing artificial wants to be the incentives and also the rewards for increased exertion. On the contrary, we believe that the many and distracting cares and pursuits of trade and commerce are, if not destructive, at least severely trying to the health of both body and mind.

The whole current of these remarks, together with certain speculations on the life of trees, have called to our mind the following magnificent passage from Louth's Isaiah, and it is peculiarly appropriate to the season, many happy returns of which we wish our readers.

"I will exult in Jerusalem and rejoice in my people,
And there shall not be heard any more therein
The voice of weeping and the voice of a distressful cry;
No more shall there be an infant short-lived,
Nor an old man who hath not fulfilled his days.
For he that dieth at an hundred years shall die [young],
And the sinner that dieth at an hundred years shall be accursed;
And they shall build houses and shall inhabit them,
And they shall plant vineyards, and shall eat the fruit thereof.
They shall not build and another inhabit,
They shall not plant and another eat.
For as the days of a tree shall be the days of my people,
And they shall wear out the works of their own hands.
My chosen shall not labour in vain,
Neither shall they generate a short lived race."

J. J.

A *Metropolitan Poultry Show*, at the Baker Street Bazaar, is announced for the 10th of January next, and the three following days. The prizes are liberal, and will, doubtless, invite competition, since no less a sum than £17 is allotted to Spanish, and £21 to Dorkings.

* The following singular authorities, among others, appear somewhat to favour this notion. Herodotus, on the Macrobian or long-lived Ethiopians—a dogma of the Etruscans quoted by Niebuhr; Louis Cornaro referred to by Abernethy; Clerk's (Fleury's) Ancient Israelites; Lingard on the Primitive Church at the destruction of Jerusalem, with a reference to these words, "the meek shall inherit the earth;" Dean Gravelly on the state of the Holy Land at its first colonization at the time of the Judges; Pictorial History of England on our own Saxon times; and lastly, Dr. Van Oven, Lee, Chadwick, to Dr. Cumming, and the Bishop of London.

For both these families a new class has been formed, namely, one for "*the best Cock (or Hen) of any age*," a wise step, wherever the funds may allow of it. At the end of Shanghaes we have Class 22 for "*Brahma Poetras*," so we apprehend that the framers of this list have satisfied their minds on a point on which our own are still in grave doubt. Game Fowls and Hamburgs are arranged as usual, but Pelds are granted a fourth class for those of "*any other colour*" beyond the Gold, the Silver, and the White-crested Black.

Class 50 offers prizes "to the most useful cross-bred fowls," a novel feature in our principal Poultry Exhibitions, and which we should like to see accompanied by the warning, that such crosses must not be bred from, but devoted wholly to the kitchen. Geese have only an equal premium with each variety of Bantams, £1 10s. being all that is offered for them. They would have merited, we think, greater liberality, and the neighbourhood of London can produce specimens of the highest excellence.

The owners of Pigeons have great inducements laid before them; and "Rabbits" also are invited.

Prohibitory prices, we are glad to find, are here done away with; and "*not for sale*" may be affixed to pens with which the owners have no desire to part.

We are glad to find that the experience of the Secretaries, Messrs. Houghton and Catling, will secure to exhibitors that care and attention for their birds, without which great hazards must always be incurred.

We must not, however, refrain from the repetition of our strong reprehension of the Show being continued for four days. For a *whole week* must the birds be shut up in the pens, for they are to be in the Bazaar on one Saturday, and cannot be released until the Saturday following! If they have to travel from a distance they must be in their basket on the Friday previous, so that for nine days they must be in close confinement! Now, at Leeds, where there there was similar imprisonment, we know of birds that arrived dead and dying—birds, too, that had taken first prizes!

We have been applied to for information as to who form the Committee of the Metropolitan Show, but we are not able to give such information. It would be satisfactory to the public if the names were published.

Neither does the disparity in the Prize List give general satisfaction, as the following letter testifies.

"As the organ of the Poultry Fanciers, I beg to draw your attention to the Prize List of the approaching Exhibition in Baker Street, and would, through the same medium, urge on breeders the propriety of withholding *all specimens* of the Poland, Hamburg, Game, and Bantam species, for which you will see that the prizes offered are little better than *one-third* of those for Spanish, Dorking, and Cochins. Promoters of these shows should bear in mind that they are rendered attractive to the public in proportion to the variety of the birds, and that although a Spanish breeder pays comparatively little attention to other breeds, it is not so with the mass of the visitors. The question is entirely in the hands of exhibitors, who have only to resolve to exhibit at no show in which the prizes are not equal for *all*.

"In this particular case I know one very successful exhibitor who will not have a single pen, although before seeing the list he had intended to send several. It is always an

expensive thing to exhibit, and persons ought not to be *certain* to make a loss even if they take a prize, which would be the case with Bantams coming from the country."

We regret to notice that the Prize List for the *Hereford Poultry Show* has followed the old error of saving their premiums by confounding distinct varieties of fowls in a single class. Thus, for instance, all the four kinds of Hamburgs compete together, and the same with Polands, Bantams, and Ducks. The principle is an erroneous one, unsatisfactory to the exhibitor and the public, while it imposes an unfair task on the judge. In the infancy of Poultry Societies such mistakes were unavoidable, but now it is far better to have no show whatever than to conduct it on a bad system.

FRUIT-CULTURE.

A FEW weeks since (page 180) my respected friend and coadjutor, Mr. Fish, took occasion to call attention to my practice in hardy fruit-culture, and introduced an extract from a letter which it appears had been written by some gentleman who had visited our gardens during the past fruit season, and who spoke in warm terms of his impressions concerning the fruits. I cannot imagine who the gentleman may be, but I hereby tender him my best thanks for his good wishes both to myself and fruit-culture, and also for affording me an opportunity of occasionally bringing the matter before our readers, although to some it may appear a thrice-told tale. It somehow happens that even the most self-evident truths require to be repeated, again and again, before they can attract sufficient attention, or leave that impress in the human mind which shall bring forth fruit, or, in other words, cause the reader not only to think but to act.

In my practice there are no secrets. I am not particularly partial to mysteries, and, indeed, if I were, I do not think that I could manufacture them out of such materials. Simplicity is the basis; for I have long held the opinion that in fruit-culture any roundabout plan, involving, of course, much expense, is unworthy of consideration. Plans, systems, call them what we will, may be ingenious, may be illustrative; but, to be generally useful to a utilitarian public, they *must* possess two other qualifications—they must be economic, and afford every possible chance of success. They should, moreover, possess so much simplicity in carrying out, that any thinking person, although unacquainted with gardening matters, might carry them out without difficulty.

The fact is, that the question of fruit-culture was fairly overlaid, a score or two years since, by systems of pruning. So elaborate had they become, and withal looked so charming on paper, that folks had almost forgotten that fruit-trees have roots which will as little bear to be treated with indifference as the branches.

I do not here intend to attempt a settlement of the long-pending quarrel between the Messrs. Prune-all and Prune-none, as these fierce belligerents have opened the question entirely in their own way. I, for one, am content to let them settle it in like manner; I advocate common-sense pruning.

It is now some twenty-four years since my attention became strongly attracted towards the question of fruit-tree culture. Having been born and bred in a nursery containing twenty-four acres, and in which quantities of fruit-trees were grown, I had every opportunity of witnessing, during my early days, the various "rule-of-thumb" processes considered requisite by the knowing ones of those times. Physiological enquiries concerning the functions of plants, trees, &c., were confined to a very limited sphere of operation; and, indeed, if any

one in those days had held such dreamings, he would have found it particularly expedient to keep them almost hermetically sealed, for it would have been excessively prejudicial to his reputation amongst "sound men" to broach such gimerack notions. I well remember a very ingenious gentleman, who had been studying Sir J. Sinclair, coming frequently to the said nursery to chat a little time away with the ground foreman, his conversation generally smacking of chemistry. He was attempting to get old John to classify soils; but not so. John, although apparently very attentive at the time, always persisted in calling him "Dr. Calcareous" behind his back—this term being the only one John could remember out of the whole vocabulary.

However, I must back to my subject. Twenty years ago, and more, then, having been drawn somewhat closely to a consideration of the hows and whys of fruit-culture, I could not help being struck with the fact that our ordinary fruits were not unfrequently more fruitful in the hands of the cottager, or in a state of nature, than in the pampered condition in which we might see them in the kitchen-gardens of the noble and the affluent, with all the paraphernalia of highly-wrought borders, and other expensive affairs. In those days I could never pass an old orchard Pear-tree, of perhaps a century's standing, or more, without reflecting how it came to pass that such trees should bear so heavily without the pruner's aid. In the garden case, I saw that the general character of the young wood was totally different; rambling trees, with coarse breast-wood, appearing as though they were cultivated for the sake of their spray; in the natural case—or accidental, if you will—the trees producing some three or four inches only of young shoot annually, and that, too, chiefly at the terminal points. Old Thorns, too, Hollies, and I can scarcely say what, all seemed to point to some great fact, and one which I was exceedingly desirous to ascertain. I felt persuaded that, say what people would about this and that tree being tender and requiring coaxing, there was some radical mistake in the culture, and that all the arguments which had been used to justify usages were fallacious, and merely meant to hide what could not be explained in a satisfactory way. I felt assured, betimes, of one thing, that no system of pruning could ever prove satisfactory in itself, whatever might be its merits, unless accompanied by certain root conditions of even greater import.

Knowing, of course, that all old kitchen-gardens were rich in decayed vegetable matter, even to repletion; knowing, also, that gardeners, in general, were compelled to crop such soils as close as the line could be drawn; and that in so doing, coupled with a constant necessity for manuring on behalf of vegetable culture, I felt assured that gardeners in general had been inviegled into a species of self-deception; and that when their fruits failed, although their Cauliflowers and Celery succeeded, that they were forced to cover their retreat by making all look nice on the wall, or by neat pruning systems.

And not only the wall borders; but those of the open kitchen-garden partook of the same character, as well they might. These things, I say, then, led me at once to the conclusion, that an unworthy compromise had been made, and that these practices were fundamentally wrong; and that the question of fruit-culture required to be considered in itself, totally apart from vegetable culture; for I felt persuaded, that so long as the two cases were kept in a mixed condition, so long would erroneous practices prevail.

The question being thus shorn of its extra appurtenances stood on its own foundation; and the mind thus unfettered (in other cases than Pears or Cabbages) begins to think anew on the subject; or, in other words, approaches the case with less prejudice.

And now arose, in my mind, the idea of attempting to

realise by art what was found desirable in trees under natural conditions. Let us take a subject by way of illustration. Here is an old Thorn-tree which has stood for a series of years; we have seldom known it fail of a crop of haws. Beside it is a recently-planted quickset hedge, every plant in which claims to be a relative of you old Thorn-tree. But these roguish young Thorns do not bear berries! The soil is good, and they have been regularly clipped, whilst the old Thorn has been neglected: it needs no shears. Now, I know, of course, that a Thorn is not a Pear; but I do know, also, that in the eyes of first-rate men, who combine science with practice, it will furnish as apt an illustration as they would desire.

Admitting this for the sake of argument, the ingenious young reader will naturally ask, what then can be done to make these young Thorns hasten their bearing? I will tell you, my young friends. Stay your hand with the shears, and apply the same amount of cutting-off to the root; but, nevertheless, thin out the branches instead of dubbing them; for even a Thorn-tree requires a certain amount of light during an English summer, to enable it to mature blossom for the next year.

To return from this digression;—I found that three-parts of the fruit-trees in our gardens were in a similar condition to the young Thorns in the hedge, and that no system of pruning could alone place these trees in a fruit-bearing condition. It appeared evident that the root was too active, or too highly fed for the exceedingly limited amount of branches and foliage; and that in such cases, either the branches must be allowed to develop themselves with more freedom, or the supplies must be, in part, cut away. This led, of course, to root-pruning, which I have, indeed, practised for twenty-four years, although it is the fashion with some to make a fuss about it now, as if it were a tolerably fresh idea.

But this root-pruning, although a preventive measure, requires to be repeated in many cases; and it occurred to me that something of a more remedial character might be adopted. Hence the idea of *Stations* occurred; or, in other words, the so placing a tree, as that its roots could, at any time, be placed in a completely isolated position, and its supplies of food apportioned to its real needs with the utmost precision. Those who are interested in this part of the question will find that this view of affairs originated entirely with myself; but the first time I made them public, I believe, was in "Maund's Botanist and Fruitist," about a dozen years since.

As years have rolled on, I have had ample opportunities of testing the soundness of these views; and I speak *emphatically*, albeit, such must of necessity appear somewhat egotistic; however, there is little use in mincing over the matter; and I will endeavour occasionally to show our young readers how to proceed in such affairs.

Could I long since have fully carried out my views in hardy fruit-culture, I think I could have shown such a case in practice by this time as would have settled the question; and, as it is, our success has certainly been very great, especially in seasons notorious for failures, and that, too, in places considered models in the world of gardening. Our Pears were, indeed, worth looking at; and as for out-door Peaches, as I have said before, we have not missed a full crop for years; but we have no heated walls.

The worst question we country gardeners have to deal with is that of economising labour so as to meet all demands; this is by far more difficult than anything in the nature of gardening; so the world must not judge us as we are entirely, but as we hope to be.

R. ERRINGTON.

PRUNING.

An intimate friend of mine was once engaging himself to a great country gentleman; and when he told me about the bargain they made, and the conversation that passed between them at the time, I was so struck with one of the qualifications which the gentleman hoped his new gardener would have, in the absence of another qualification, on which he did not seem to put much stress, that I shall never forget it. "I know your character stands high, and you have the credit of being what is called a scientific gardener; but, for my own part, I do not much value that quality; it is apt to make some men think more of themselves than they ought to do; and, besides, if I can get plenty of flowers and fruit all the year round, and the place is kept as I wish it, I think we could dispense with science, thus far in the country, or, at least, we need not put much stress on it." Another gentleman, who reads *THE COTTAGE GARDENER*, made another remark, in a letter to myself, sixteen years since, which I shall never forget. "Not only a gardener, but every cook and groom, ought to know, or be informed in the science which bears on their departments, before they are admitted into large establishments, where the health of the family and most valuable property are entrusted to their care." I quite agreed with this correspondent, although, previously, I did not look upon cooking and grooming in that light; for I was a man-cook in three establishments, without considering that it was necessary to catch a hare before cooking it; and I could ride the wild-cat colt up or down a steep *brae*, or plunge into the stream without a saddle, and swim across, without being aware that any science at all was necessary in the matter; but I never yet believed that a man ought to be allowed to prune a gooseberry bush until such time as he could give a good sound reason for every cut he made; and if he could do that, I would call it scientific indeed, although he might call it only practical knowledge—sound practical knowledge being the only sure foundation for practical science, after all.

If you stand before a young tree, not higher than your head, and see one or more of the side-branches so much stronger than the rest, with their ends more upright—showing plainly that they, too, would be leaders in time, as much so as the centre and true leader—science teaches that if the top, or tops, are merely cut off or stopped, the ascending force is divided, and the leading character is lost, from that hour, to those shoots. But science may be at fault for all that; and practice alone must guide the pruner as to which of four buds to cut to. If you take the point of a shoot, and bend it to you, there are eyes, or buds, on the upper side of it, also on the under side, and on the right and left sides as well. Now, the question is, to which of these buds is the shoot to be cut to; and to that science cannot direct you, at least not to three of them, science being based on fundamental rules. If you understand it, you will never cut a side-branch, in any tree or bush, to a bud directly on the upper side of it; because it is natural, or fundamental, that the top bud left on the upper side will either take the lead, or, by growing inwards, crowd the distance between it and the stem or trunk of the tree. A pruner may work to get more flowers, more fruit, or timber, or he may only want a more regular disposition of the branches; but none of these can be had by crowding them: still there are three more chances in the three buds left out of the four; but as science does not go by chance, it cannot tell which of the three buds is the right one to cut to. If you cut to a bud on the under-side of the shoot, that bud will make a shoot that will grow outwards; and if there is room in that direction, that is the best way for it to grow: but, suppose there is another shoot which

occupies, or which will soon occupy, that space, then your causing a new one to grow in that direction will crowd that part; therefore, cutting to an under-side bud, in such a case, is manifestly wrong.

Let us now take a bud on the left side of the shoot, and cut to it. This also may be right or wrong, as it happens. A leader rising from the left side of a shoot will grow more to the left than the shoot itself would do were it not stopped; and if that left side is already better furnished than the right side, there will be more crowding than needs be; and it is just the same on the right side of the branch. Here, then, we have got science and practice just matched, the one helping the other in equal proportions, or "value for value," as the greedy hypocrite said, when he gave away his cuttings, with the only view of doubling his own collection.

This teaches us to stop an aspiring leader to lessen its force in that direction; never to stop it to a bud on the upper side of it, and to be guided to the right bud to cut to by the rest of the branches; choosing the bud on that side where they are less crowded, and so, by directing a new growth to the more open part of the head, balancing the whole more equally.

I put the question, which is the root and foundation of all pruning on this footing, because, in nine cases out of ten, in general pruning, it stands just as here set forth; though never, or but in very rare cases, in pruning a forest or timber tree: for exceptions, take a pillar rose? If one of them, or one out of every hundred of them, were to be led up with one central stem, like a forest tree, the chances are that it would get bare at the bottom, some time or other; and if it did, there is no other shoot to fall back upon, or rather to cut back to furnish the feathers to the ground; therefore, the safest plan is to have two, three, or more leaders, for the centre of a *pillar-rose*, and, in pruning the side-branches from them, we meet with exceptional cases to that of not pruning back to a bud on the upper side of a timber tree. We want the pillar to rise as fast as practicable, after furnishing side-branches enough to form the body; and if we always avoided the cut to an opposite bud, we might have more for the body of the pillar than was really necessary, and not enough of upright growth to carry on the height in proportion. In such cases, if we are sure of sufficient side-branches, it is always best to cut back to a bud on the upper side of all the topmost branches. On the other hand, if we take the care of *fruit-trees trained* against something, or of flowering plants merely, trained the same way, and find that the young wood from the main branches is too strong for our purpose, we prune back to a bud on the under side of the shoot, because a shoot from such under bud is never so strong as one from the upper side.

Such, then, I conceive to be the rudiment or first principles of pruning. The very first move in the process is merely to squeeze the leading bud on a twig or branch between the finger and thumb, without an external wound, the soft parts inside the bud being only affected by the squeeze so much as to hinder the growth in that direction. The second step removes the bud altogether, and the third involves the cutting off of a portion of the wood as well—the practical eye directing the hand to where and to what extent the removal is to be made, and that the quantity to be cut off, and the bud at which we must stop, must necessarily vary on the same branch, according to the purpose intended by the pruner. Another maxim is this—pruning will add very much to the size and weight of a great variety of fruit, by confining the energies of the parts next to the fruit, for that very purpose, instead of being expended in making more wood; but all the pruning we can do, except in very rare cases indeed, will not add one inch, or one ounce, to the size or weight of a tree, although more than half the pruners in the world believe to the

contrary. Why, then, should timber trees be pruned at all? Mr. Appleby will tell us why when he comes to that part of his instructions to the royal forest commissioners; and here I shall confine my observations to the effects that may be produced by pruning the large outside trees along the boundary of villa gardens—trees, indeed, that have been, for ages, much worse managed than all the trees in all the forests in the country have been, in this age more particularly; and they say that is bad enough.

The next step in pruning, after stopping buds and aspiring leaders, is a process which every gardener and forester puts in practice every season, and, curiously enough, no one has ever yet thought proper to explain it in print, as far as my reading goes. Take up any book or essay on foresting, and you will find the first step in pruning recommends that aspiring leaders be stopped; and the second rule to prune off the lowest tier of branches, after a certain age, and before the branches are more than one inch in diameter; but there is a step between the two which is never omitted in practice—it is so difficult, however, to explain it by the pen, that all writers pass it by, or take it for granted that any one who is competent to prune at all must know of it without being told. Let us suppose a common case, however: A young, healthy tree, six or seven feet high, is removed from the nursery, and is planted along the boundary line of a villa garden, where it is intended for a screen more than for its timber; and let us say that the first three feet of it from the ground is without any branches, then a thick head of branches, with all the big ones about the same size, and none of them seeming to vie with the leader, which is freely setting off in the middle without a rival—just such a tree as one would select out of a whole nursery row. When this tree begins to make a free growth after planting, the pruner comes round in the winter to see that all is right; he finds no necessity for the first step in pruning in this tree—namely, to stop a too forward branch—for there is none of that class; then, if he is not a practical hand at the knife he will do just what the book tells him—misses the second step altogether, and takes off the lowest tier of branches, which is the third step. Here he would be wrong in two ways: first, he is not pruning for getting clean, straight timber, therefore, there is no need of depriving his tree of its lowest branches; and secondly, he will need them all by-and-by for screening the garden. The common lot of all planting for screens is, the plants are set too thick, and the one soon spoils the other by over-shading, and all get bare at the bottom as fast as the tops rise, and so on they go till you see right through them, and then the usual means of hiding the boundary a second time with evergreens is had recourse to. Now, what is right of pruning boundary trees is right about planting them; they ought to be planted rather thinner, or wider apart, in the first instance, and in pruning them the branches ought to be *thinned* when they grow close together, so as to keep the one from shading the other, that all may live for a long time, and form a perfect screen; taking off the lowest tier is of little use, and may do harm, by depriving you of the number of screens; it is the *equal distribution* of the branches all over the tree that is required, and our young tree from the nursery, with a fine head of branches, has now arrived at that stage when the growth of these branches causes them to be too close together, and they ought to be thinned as surely as a young forest plantation should be, or any other plantation that was planted thick at first; the practiced eye would see this at once, but the most practical pen could not say at a distance which of the branches or how many of them ought to be cut off, so as that the head should not be crowded for another year; then it follows that the second step in pruning should be

to see that the branches are not crowded in any part of the head; and the third step, that of cutting away the lowest tier should never be taken until the second step, that of thinning the head, was accomplished; therefore, when we know that too much pruning at one time hurts a tree, if the necessary thinning happens to require more than the value of two bottom tiers to be removed, the third step should not take place at all that season. A tree taken thus early should be so managed, to the last day of its life, as that no branch need be cut from the main trunk of more than one inch in diameter. A wound made by such a cut will be healed over by new wood the first season, and leave no blemish in the wood. I never yet spoke to a man about the necessity of stopping a branch that was stronger than its fellows, who could not understand the reason in one minute. We all agree that there must be a leader in parties, creeds, and kingdoms, as well as in trees; and when another tries to get the upper hand things go wrong and out of joint, and we stop him; but there is not one in ten who understands the reason for thinning the head of a tree before the pruning for straight timber begins. It is not every one who knows the use and value of leaves that can understand how it is that leaves can be useless, or injurious; but they can be both; part of the things which go to make timber, or fruit, go also to make leaves; but unless leaves are allowed full exposure to the light they are of no use to the tree; and what goes to make an useless leaf is an useless expediture, and therefore an injury so far. So much for the first three steps in pruning, and now to conclude—Who will take me to task about saying that pruning does not “add an inch or an ounce” to the length or weight of a timber tree? Here is a fine chance for some of our young readers, in one of the easiest and simplest kind of writing, namely, hard criticism; the harder the better, if it is courteous. D. BEATON.

DISAPPOINTMENTS IN WINDOW-GARDENING.

“OUR window is all our domain; no *terra firma* belongs to us, unless that which is situated there, but the small quantity of earth contained in boxes and flower-pots is as dear to us as the soil in the boots of the Barons of olden time, when at the coronation of a king they could severally boast that each rendered homage standing upon his own soil; and yet how careless you are of us, never telling us *when* the frost would come, or giving us full information, except in far back volumes, how to act. And there now, my soil in pots is pressed hard as a brick; and the plants on which I took so much pains are past redemption. Alack a day! what shall I do?” In a market town, where there are some nice little gardens, where the windows during the spring and summer months are well stocked with flowering-plants, and this holding good, not only as respects the middle classes, but applying equally to the homes of the mechanics, and not a few of the more unskilled labourers; a nurseryman told me—and his manner betokened that he had not a spark of a notion that ever I put words on paper—“these scribbling fellows that let out all the secrets about this plant and that plant are really the best friends to us; for do you see, they make such commonish things look so grand, that ladies ask their gardeners if they have got such a thing, and forthwith we get an order; and others, who have a man so many days a-week, resolve upon being economical, because these writing men tell them how easily such and such things can be kept over the winter, and they propagate wholesale, and give a good order for pots, and all goes merry as a marriage bell, until some day or night, when the good jobbing-man, who could

not be in two places at once, is out of the way, the plants are freezed, and as they will not be beat, I have, in all such cases of ordering of pots in autumn, felt half assured of receiving an order for plants in spring, and then, Sir, almost all our better-to-do sort of people, who make a pride of keeping their plants in windows over the season, meet with so many accidents, from a little want of thought and attention at the right time, that they readily give us a sum for a few nice plants, which they would not be inclined to do had they not known something practically of the labour and attention that were requisite to keep the plants healthy.” Now, if our friend has no other resources, we think we can here point to one remedy for his grievance, namely—the nearest respectable nurseryman.

A learned man we lately heard preach, said—“If you ask me what the morrow will be at this time, I reply, I do not know; wait till then, and I will tell you.” Now, to some extent, the same answer applies to our friend, as to telling him what the weather should be in our uncertain climate. We can only give general rules in such matters. The reducing of a general principle to particular cases must be left entirely to the judgment and forethought of the parties concerned. We can never supply mere continued observation, and the deducing of inferences from it, as to what the weather will be. Without, however, *waiting*, like the learned Doctor, we can, from certain circumstances, such as the direction of the wind, the absence or presence of clouds, the state of the thermometer and barometer, judge pretty accurately what the weather is likely to be for short intervals of time. For instance, last Monday evening, though it was freezing fast, I predicted, from the presence of large fleecy clouds, that it would be milder before morning; and the following morning and day were, for the season, rather warm. These matters, however, were entered into rather fully some time ago. They are worthy of the study, not merely of our friends the amateurs, but, in these economical days of the practical gardener. Just think how much might be saved in fuel did the furnace-man keep his eye on the sky, the wind, and the thermometer in the shade alone: there would be less irregularity in houses, less overheating of them, less waste of fuel, by sending in dampers and opening the furnace doors that the valuable heat may be spent on the external air, because it would be injurious to admit it into the house. I passed such a furnace at night not so long ago, and the able gardener, under whose superintendence the place was, said nothing could be more vexing, as the waste thus occasioned, in districts where coal had to be driven long distances. He added, “I have more bother with this than anything else.” A young gardener once showed me a letter he intended sending to a periodical, showing the importance of noting the outside thermometer in the management of houses; and I said, “It is very well, but surely such an article could not be needed—I myself had been so accustomed, when a furnace-man, to look to the glass before I went into a house, or touched a fire.” He assured me that in a large establishment he never saw it done; and I can partly believe it, as I have long found that in the case of young men attending houses it requires some scores of questions as to the condition of the outside thermometer in a winter’s evening, before any other answer can be got than “I don’t know,” or “I forgot to look.” Now, in these competing days it requires no prophecy to foretel that such easy-going unobservant persons stand a good chance not to be looked at but *forgotten*.

“I have had a handsome bow sash made for my window, retaining the common sash as before, there being nothing different from a window with double sashes, farther than that the outside one projected more than ordinary, and in the space between I have kept my

plants well, being able to give them air, &c., when it might not be desirable to air the room; but now you have got me nearly into a scrape; for relying on what you said, as to the non-conducting properties of confined air, I did not move the plants in these cold nights, and notwithstanding there had been a fire in the room, some of the foliage was slightly injured." There is such a thing as carrying a principle to an extreme. A *good* non-conductor of heat, and a *perfect* one, are very different things. I never asked for confined air, what its proprietors propound for *frigidomo*, namely, that beneath it there would be no change of temperature. I can believe it to be a capital protecting material, although several folds of it would not secure what it pretends to do in a cold night. If confined air was *altogether* impervious to heat, then the warmth of your room would have as little effect on the one side as the frost without on the other. Bounded on each side by a wall of glass, a substance easily affected by changes of temperature, the air next to the glass would be affected by the heat on the one side and the cold on the other. But in proportion to the complete isolation of the enclosed air would be the obstacle to the uniform temperature within, by the free passage of heat on the one side, and of cold on the other. I can conceive it very possible that three distinct temperatures may exist in such an enclosed space, and that therefore leaves six inches from the glass might be frozen, while those double that distance would be safe. Besides, let it not be forgotten, that every hole and cranny are so many means for setting the air in motion, destroying its isolation, and making it a conductor instead of a non-conductor.

Even with such holes, an advantage is so far gained, because free radiation is intercepted. For example, the best security we could give to a sash over a cold frame, or pot, from frost, would be the covering it with an opaque substance that could neither be easily heated nor cooled, raising that covering several inches above the glass, and then securing it all round the sides and ends, so that air shall not easily come out or go in. We thus alike prevent the radiation and conduction of heat. But suppose we place such a covering over a sash, and leave the sides and ends open, we certainly so far prevent the free radiation of heat, but we allow the rather free egress and ingress of air to conduct it away. Hence, in cases where close shutters outside would be undesirable in the coldest nights, the plants should be moved from the outside glass; in very cold weather they should be taken into the room altogether; and in cases where double sashes are not used, the plants, as often advised, should be placed in the middle of the room at night.

I have been told of several very successful adaptations of this double or bow window style, so as to resemble a miniature greenhouse, and I have no doubt they will become more general, as they are really more interesting than the pretty toys of Ward's cases, just on the principle, that three-parts of the pleasure to be derived from plants consist in the being able to attend to and supply their many wants. Picture to yourselves such an enclosed space, say from eighteen inches to three feet in width, see it arranged with little baskets and vases, and stands filled with flowering-plants, with openings in the external sash, so that in suitable weather you may give air, water, wash, syringe, &c., without making, what the ladies are apt to call, a *mess* in the parlour, unless their own hands should have wielded the water-pail, &c., and then it is all right. Think of the ability to give these plants air, &c., when you could not make the slightest draught from the window into the room; on account of the dear invalid reclining on the sofa, and the *thanks* that dear friend would *look* far more heart-reaching than the balmiest

words, when, after the room was all comfortable, the plants washed so as to be as fresh as a daisy after a shower, you shut up your external ventilators, throw up the sash of your inside windows, and, amid beauty and odours, causing the mind of your friend to forget the distress of the present amidst the flowery recollections of the past, and the more than sunny hopes of the future. And for such a delight to others even, let alone the pleasure to ourselves, would not the trouble and the care sink into insignificance? You say, that if you had fixed stages, baskets, &c., in such a place, that there would be an annoyance in getting them into the room in frosty nights and days, however beautiful the sight might be in summer. Well, let them alone where they are. Procure a waterproofed cloth so as to cover the outside of the window, well padded, and large enough to be fixed securely at the sides. In cold nights, and even days, admit a little air from the room among the plants, and when very severe, place a gallon stone-bottle, filled with hot water, in the miniature greenhouse before retiring to rest.

I believe, that in the case of all who can afford the comfort of the real luxury of having a cool room in summer and a warm one in winter, that double windows will become a sort of necessary, even when plants are not cultivated between them. Air may then be given at pleasure, and yet the counter-action to a free radiation and diffusion of heat will serve to maintain a more equable temperature within. As a medium for plant growing, I think, that under various modifications, the idea is destined to be a popular one. Many think plants *unhealthy* in rooms, as giving out deleterious gases by night and in dark evenings. Unless, in the case where odours, pleasant or otherwise, are very powerful, I think too much stress has been laid upon this, but all agree, that whatever be the influence of vegetation during the night, it does, while healthy and clean, improve and purify our atmosphere during the day. These double cases would allow the needlessly timid to shut out the deleterious gases and exhalations, when dark, either in a bed-room or sitting room, while they could enjoy their exhilarating influence during the day.

With pleasure I notice that this idea is to form a prominent one in the government rules for the new cemeteries. Whatever the inside arrangement, it is to be imperative the surrounding of it with a belt of vegetation of trees and shrubs; not so much for shade and beauty as for neutralising the exhalations from decomposing matter, and thus so far afford a healthy atmosphere. Government here is following out, at however humble a distance, the teachings of the noblest of all philosophy, be it reverently spoken, the example of the Great Architect of Nature himself. Before animals could poison the air with their breath and decomposition the counterpoison had already been prepared. Vegetation had spread its verdant mantle over our earth, and the sunbeam had played upon its foliage, thus eliciting pure oxygenated, inspiring, vital air, before present animal forms had been called to take their position in this beautiful world.

R. FISH.

THE IRIS.

(Continued from page 242.)

IRIS SUSIANA (The Shiraz Iris).—This, though one of medium stature, has an uncommonly large flower, and on account of its singularly-blended colours is exceedingly interesting and quite a striking beauty. It is, however, not generally grown, but certainly deserves to be, because its flowers are so large and finely-coloured in streaks of rich purple. It is not strictly a bulb, but has a fleshy, roundish kind of root-stalk. I

had a lot of it from Holland this season, and they came over quite safe, were potted immediately, and are now growing well.

The soil this species requires is a rather strong one; that is, a compost of three-parts good loam, such as an old pasture will afford, one-part well decomposed hotbed manure, or the horse-droppings from off our public highways. If the former manure is used, then add a good addition of sand; the latter will, perhaps, not require it, because sand, or, at least, grated stone, will generally be scraped up with the dung. In this material I find them to grow very satisfactorily. The *Shusun Iris* is nearly hardy in the south of England, but is apt to go off with the damp weather of autumn; therefore it is safer always to keep a few in pots, sheltered through winter in a cold frame or pit.

At Messrs. Henderson's, of Pine-Apple-Place, it is kept plunged in a pit, which pit is simply protected with mats thrown over a frame-work made of iron rods length ways, and bent over in half-circles at about seven feet apart across the pit or bed. It is one of the neatest habitations for half-hardy bulbous plants I know of anywhere. It is a winter habitation for rarer kinds of Squill (*Scilla*), for the *Bulbocodium vernum*, for the *Cyclobotrys*, *Rigidellas*, and other rare, scarce, half-hardy, and difficult-to-do-well bulbs. The pit is simply a parallelogram formed by building two walls four feet apart, about one-and-a-half feet high, with cross walls at each end. It is filled with brick rubble to within six inches of the top, and that space is filled with ashes, in which the pots are plunged up to the rim; then on the top of the bricks is placed a long piece of timber, about the size of a brick in the square. Into this sill the iron hoops are fixed, thus rendering all firm and substantial. It has been in use, to my knowledge, for more than ten years, and is apparently quite as perfect now as the day it was built and finished. An additional shelter is given to it by a thick, four-feet high, Yew hedge on the north side. So convinced am I of the excellence of this hybernaculum, that I shall put one up for my own use. I am certain it would be an excellent place for many things that are now damping off in close pits or frames; such, for instance, as Verbenas and shrubby Calceolarias, plants that invariably suffer more, or rather perish more, from damp than the severest cold. In such an airy pit damp would vanish every fine day, and frost might be kept out, or from the plants, by coverings of non-conducting materials, such as that called *frigidoma*, which I have seen in use at Dyrham Park, near Barnet, and which the excellent and scientific gardener, Mr. O. Thomson, assured me was the best covering material either for shade or shelter of which he had ever had experience.

This is a digression in favour of a pit, or rather, perhaps, it might be termed a raised and sheltered bed, which I am sure the readers of THE COTTAGE GARDENER will excuse, nay, many of them will be glad of the information how to form such a place. Whoever visits the Pine-Apple Nursery should request to be shown this raised bed in which are grown the rarer bulbs in pots. Its neatness and efficiency would be sure to gratify the visitor. The only fault I could ever find about it was the hedge being a little too near it, so that there is scarcely room to creep along between the pit and the hedge.

After the winter season is over, this beautiful Iris may then be planted out to bloom, and taken up again in the autumn. It is easily propagated by division. On each side of the fleshy root-stock there springs forth shoots; these gradually elongate till they have a root-stock belonging to each. This young root-stock will form roots, and then it may be safely divided off the parent plant, potted in a proportionate sized pot, and placed in a shady place till fresh roots are emitted, and the plant is fairly esta-

blished; afterwards give it a second potting, and then it may be treated like the old plants. The species also produces seeds, and may be increased by them as a matter of course; but hitherto there has been no disposition to (as florists term it) sport. All the seedlings have come exactly like the parents. Whether a Beaton, or a Leeds, could, by hybridizing, produce such a result, I must leave to them; the flower is really such a fine one that it seems almost impossible to improve it.

One point in its culture I must not forget. If a plant has become old, and branchy, and weak, then it will be advisable to break it up entirely, make of it as many as possible, and commence afresh. T. APPELBY.

(To be continued.)

ENVILLE PARK,

THE SEAT OF THE EARL OF STAMFORD AND WARRINGTON.

WHEREVER there are improvements taking place, or going on, I am pretty certain to hear of them, and quite as certain to go and see them, and also to take notes; and, as Burns says, "I faith to prent them." A very good and entertaining book might be written on the progress of gardening, and we should find, that in proportion as the taste for gardening increases or wanes, so will the taste for all that is good or lovely in the moral world increase or wane also. Great Britain stands, perhaps, the highest of any nation or kingdom, ancient or modern, as a gardening people; and I need not insist upon the moral and intellectual superiority of her people. Long may gardening flourish among us, especially the ornamental part of it; for I say, increase the love of flowers, and the lovely part of the human character will be developed in proportion.

Enville is quite a household word among Pine-growers. It was here that the kind known as the *Enville* was either raised from seed, or first fruited, and hence took its name.

The place is situated about five miles from Stourbridge, a town famous for the manufacture of glass, and the boundary on that side of the *black country*. I was staying, about a month ago, a few days with my esteemed friend, Mr. Catling, curator of the Birmingham Botanic Gardens, and whilst there, I heard that Lord Stamford was making great improvements in his gardens. That news induced me to start forth on a journey of discovery through what is called "the black country." Whoever has read the beautiful story of Nell and her Grandfather, in Dickens "Old Curiosity Shop," will remember his vivid description of this country. It commences as soon as the passenger leaves the noble station of the London and North Western Railway, in New Street, Birmingham, and stretches, without any relief, to Stourbridge. A bleak, barren, desolate, and black, smoky district, with scarcely a tree, or a hedge, or a green field to relieve the eye. Even the cottage gardens, where there are any, are barren; or, if there are a few hardy Scotch Kale plants to be seen, they are so dark coloured that the mind is distressed with the idea of having them cooked to eat. Thanks, however, to the steam and iron way, I was quickly conveyed over it, and as soon as I passed over the line of hills just beyond Stourbridge I entered into as pleasant a country as can be found anywhere in Britain.

I cheerfully pursued my way on foot, for there is no public conveyance that way, till the towers of Enville appeared in view. Every step told me that improvement was the order of the day. The hills are covered with young thriving plantations, in which the Larch appeared to preponderate greatly, though I could detect a mixture of the sturdy Oak, the graceful Ash, and the slender Birch amongst them. Doubtless the Oak is intended to be chief when the rest are thinned out. Many of these young plantations are now just at the

stage when the thinning process should be commenced. The branches are beginning to interlace, and a drawing up will take place if they are neglected even two years longer.

As I drew nearer the mansion, I observed to the right a long length of new lofty brick walls; these I found were the boundary of a large new kitchen and fruit gardens, on the south side of which is a large congregation of glass houses, nearly all in an unfinished state. Long ranges of pits are in front, and these were filled with the healthiest bedding-out plants I have seen this many a year. In one large pit there were some good healthy Pines, and in another some good Strawberry plants preparing for forcing. All, however, is in an unfinished state, but progressing surely though slowly. From this kitchen garden we, that is, the gardener, Mr. Aiton, a descendant of one of the royal gardeners of that ilk, and myself, wended our way up a rising ground to the plant-houses or conservatories. These were well filled with good, healthy plants, but they are too small and too lauciful for the place. They are to be taken down, and a much more extensive and noble range put up. I saw the stakes put down for the foundations.

The pleasure grounds are very extensive, occupying a rising ground to the north of the house. They were formed about five years ago, and it is remarkable how the Rhododendrons thrive in the soil—a kind of red clay. To look at it, I should have thought they would not have existed a single summer, but they have grown well, and are of a deep green, and well set with buds. As this pleasure ground is so extensive, advantage has been taken of that circumstance to plant a considerable number of the choicest Coniferae. I noticed the following: *Picea nobilis*, 9 feet, a handsome specimen; *P. Webbiana*, well-formed and uninjured; *Pinus patula*, a little injured; *P. macrocarpa*, a splendid specimen, 35 feet high, with a stem three feet round; *P. excelsa*, a dark green, densely branched variety; *P. ayacahuite*, 6 feet, uninjured; *Taxodium distichum*, a fine tree, 45 feet high, and 4 feet round the stem; *Abies Brononii*, quite hardy here, uninjured for four years; *Abies Douglasii*, growing rapidly; *Cupressus torulosa*, quite hardy; *C. thurifera*, much injured; *Cedrus Deodara*, many plants, growing rapidly. The Deciduous trees here are very remarkable. I do not suppose there are any such in the kingdom. They have been planted in groups of seven or nine, and the branches have spread along and over the ground to a very great extent. I think I speak within bounds when I say the branches cover a space 100 yards in diameter. Of course, they were out of leaf when I saw them; but when in full foliage they must make a grand appearance. In the pleasure grounds there are an upper and a lower lake of water. Jets are being put in, and will be very effective, no doubt, when finished.

Such is my very brief account of a nobleman's seat that is in a state of improvement. Visitors need not go through the dismal country. I did to appreciate its beauty by contrast; for there is now a railway opened from Oxford, and from that point I would advise any inhabitant of the south, desirous of seeing a fine place, to start from. Oxford, of course, can be reached easily enough from any part of the kingdom. The station for Euville is Stourbridge. In three or four years, if it goes on prosperously, this will be quite a lion in gardening.

T. APPLEBY.

ON KEEPING ICE.

THE arrival of winter brings with it duties peculiarly its own, and some of which, if not performed at the identical time they ought to be done, cannot be done at

all during the season. Amongst such duties, that of filling an ice-house, or storing the ice away elsewhere, is one important job which must never be delayed when an opportunity offers, for, the old and trite saying of "make hay while the sun shines," is not more wise than "store ice while it freezes;" for, as every one knows, good and suitable ice for storing away does not present itself every year in the south of England, especially in localities near the coast; consequently the first chance must not be lost.

There are various opinions afloat regarding the keeping of ice, some insisting that it ought to be excluded from the air as much as it is possible to make it, by a close fitting apartment, and covering of litter to an extravagant extent; while others would seem almost to intimate that a free ventilation, if not almost open exposure, was more necessary. Now, the wide difference between these two opinions leaves room for many intermediate plans or ideas, and it is amongst them that I take my stand, without impugning the veracity of those who think that ice keeps as well in an out-door heap as in a well, or house properly prepared for it. I have tried both plans, and must say that my efforts at keeping ice in an out-door heap has been, on the whole, unsatisfactory; and though others may have been more successful, might I not ask if their good fortune in keeping it did not arise from the great bulk they had stored away?

It is well known that the detached masses of ice which float southward from the Arctic Sea, often reach a temperate latitude before they are entirely melted; but it is only fair to conclude, that when they do so, they must have been of huge dimensions at the starting point; subject to the same rule, therefore, must be the ice-heaps which we have stored up in dry sheltered corners. They, too, must have been tolerably bulky to furnish the requisite quantity a family of rank often requires at the end of summer and beginning of autumn; for, be it remembered, that under whatever circumstances ice be kept, the quantity left for use in September here rarely amounts to more than one-fourth of what was stored away in winter, so wasteful a material it is to deal with, in spite of all the preservative means taken to save it.

Where, therefore, an ice-house exists, I would, by all means, advocate its being filled with the best and cleanest ice that can be got, as soon as the weather and other things admit its being so. Afterwards, I would advise an ice-heap formed somewhere, in order to test the value of the two modes. This plan I have, with one or two exceptions, adopted for many years, and the result was in favour of the ice-house. True, the outside heap was of some service, because any that was wanted during its continuance was had from there; but it always took a very large heap to last until the middle of June; and sometimes it was gone much sooner.

The plan I adopted with this heap was this:—A convenient spot, where the water would drain away, was selected near the pond the ice was taken from, and a square, or polygon, was formed by hurdles being made firm in their places. Sometimes the ice was stacked on the ground, and sometimes faggots, or brush-wood, was placed at bottom, but at all times, straw was placed at the sides against the hurdles, and the ice was then introduced, well broken beforehand, and rammed tight in its place, the same as in the ice-house; and when the top of the hurdles was attained, stakes by the side of them were driven in, or some other contrivance adopted, in order to keep up the ice, and allow the heap to be made as lofty as possible; but it is a bad thing to build; and I never saw any workman that could carry it up so as to appear anything like a "steep roof." Such as it was, it was covered over with litter, and if the place was exposed to winds, care was taken to secure the straw against being removed; nevertheless, I always had the mortification

to find my heap sadly reduced by Easter, and sometimes in the middle of May. All that remained of sixty or seventy cart loads of ice was a small portion that would have gone into one, and which, in a few days, disappeared altogether.

This was not the result of one year alone, but of several years in succession; and thence I had come to the conclusion, that an outside ice-heap was an unprofitable affair, except for the purpose of supplying any immediate wants of the family prior to opening the more important store, when my worthy coadjutor, Mr. Beaton's article on "Icebergs" appeared in these pages, about two years ago, wherein he seems to give the preference to out-door-keeping contrivances; but it is possible he may have placed a massive volume of ice in a favourable outside situation, against a smaller quantity in an indifferently constructed house—hence the result.

Now, as there are wide differences in ice-houses, and in different seasons the same house will preserve ice a longer or shorter time, according to circumstances, it is not fair to draw a general conclusion on any one season alone; but I would wish to guard parties against filling a small house with light snow, for if it be so, no ordinary amount of ramming can make it tight, and the whole volume being so much charged with air speedily dissolves. Most people seem disposed to fill it with bright clear ice on a frosty day, when the sounds it emits rings like bell metal. Whether this is the best possible condition, or not, I am far from affirming; certainly it has one advantage, it is likely to be stored away clean, for the clear frosty air keeps both it and the dirt in their respective places; but I am of opinion that it is in a more dense condition when a partial thaw has commenced, and it is more likely to get well broken then; but then it is liable to get loaded with dirt, which certainly does more harm than the benefit it is likely to derive from its increased density; besides which, the propriety of securing ice whenever the weather admits, and it is of sufficient thickness, must not be departed from. It must be proceeded with without delay, regardless of the weather and other external circumstances.

It is almost needless here urging the necessity of having the ice well broken and tightly rammed in, these duties being so well and generally known; but I would warn all who may not be already aware of the fact, that salt ought never to be used in storing away ice, for although confectioners and others use it in the preparations they make, still it is not as a preservative—in fact, it has a contrary tendency, and when it has been used, which it was strongly urged to be done some twenty years ago, the result proved its decaying influences; therefore, when an ice-house is to be filled, rather exercise what care can be done to secure the material well pounded in, and clear from dirt, leaves, grass, or other impurities; and the house being well filled up to the top, the straw need not be added until it has subsided a little, which it will do in about a month or so, when it may be covered over; otherwise, if needs be, it might be filled up with some ice that may have been left in store for that purpose, and the second receding will be the time to cover it up. However, these matters are best known to the individual cases they are meant to represent, so that in winding up this article, it is only proper to remark, that where a choice of water exists from which ice can be withdrawn, select that which contains the greatest amount of spring water of rather a hard kind, for my experience so far has proved it to furnish the best keeping ice.

J. ROBSON.

THE MANAGEMENT OF DOWN EWES AND LAMBS.

(Continued from page 241.)

My last paper upon this subject concluded with the method of making the fold-yard, and the manner of feeding the Ewes previous to lambing. It is now my intention to continue the subject in reference to the treatment of Ewes when they have yeaned, and also of the Lambs as they fall.

The weather is generally very uncertain, and often accompanied by frost and snow, at the time of lambing, with this stock; and it must be borne in mind that some exceptional management is required in consequence. To be well prepared for all contingencies, it is a good plan to have a store of roots at hand, or, what is better, to be provided with the large Drum-head Cabbages, which are not so susceptible of frost as roots, can be more readily eaten by the Ewes, and will furnish the Lambs with a better supply of milk than can be obtained when the Ewes are fed upon roots. The Ewes will, however, do well for their Lambs at the first, when fed upon any kind of common Turnips. It will also be very desirable, when convenient, that a few acres of dry pasture should be held in reserve, containing all the grass which may have grown upon it since harvest, and which, in ordinary seasons, will by this time have become hearty and useful food for the Ewes; and on this land, at the same time, they may receive roots in addition with advantage. This pasture will afford good lying for the young Lambs as fast as they fall; so that they should, with the Ewes, be removed to it, and there remain; receiving a fresh partition of grass, with roots, every day, until the period of removal into Turnips for open field-feeding. This removal should not take place until the Lambs are strong enough to encounter the difficulties which usually attend open field-feeding; which they will generally be able to do at the age of two or three weeks. The foregoing observations, however, must be considered to apply to those Lambs which come healthy and strong; but when the reverse is the case, they should, together with twin Lambs, which are usually more weakly, receive especial care and protection, by being placed in separate apartments of hurdles placed square and under cover.

It should be carefully noticed which it is that requires particular treatment, it being sometimes the Ewe, at other times the Lamb, and often both. When the Ewes are short of milk, American Linsced Cake, commonly employed for feeding purposes, should be used, ground fine, and made into gruel. This may be given to them twice a-day, in addition to the usual supply of food, with great advantage; for, although Linseed Meal may be preferable for the purpose, yet, when required for a large number, it would be somewhat expensive.

Lambs, in some seasons, suffer much in health, and great and heavy losses often occur. There are two complaints to which young Lambs are particularly liable, and which, at the same time,

often prove fatal to an alarming extent, namely, the white scour, and a rheumatic affection. The first, which is often beyond control, I have sometimes cured, when discovered in good time, with a dose of ten drops of tincture of opium, half a teaspoonful of prepared chalk, in half a wine-glass of warm water. This is sufficient for a Lamb at any age under one month, and should be repeated every three hours, until the desired effect is produced. The rheumatic complaint is first discovered by the animal becoming crippled, and losing the use of one or more legs, which swell at the joints, after which the Lamb soon becomes emaciated; and in case actual death does not ensue, they are profitless for keeping, and should be destroyed. This disease, unlike the first-named, has no remedy; but in all disorders a preventive being better than a cure, I shall endeavour to show the causes, and likeliest method of prevention. In my own flocks, for the last twenty years, I have suffered great loss by this complaint, and I attribute the causes to be, *firstly*, the Ewe having more milk than the Lamb can take; *secondly*, the insufficiency of milk, whereby the Lamb becomes unable to bear the effect of changeable and bad weather; and, *thirdly*, undue exposure in low and wet situations. The first cause should be obviated by the milk being drawn from the udder every morning, in all cases where the Lamb cannot take it, for I believe this to be the chief cause of the disease, and often the occasion of the white scour also, for by accumulation in the udder the milk becomes unwholesome. Insufficiency of milk may be in some measure rectified by the before-named use of linseed gruel. The last cause named may be removed by keeping the stock upon the driest and most sheltered parts of the farm, or by artificial protection.

The Lambs having arrived at a fortnight old, they should, with the Ewes, be placed on root-feeding; and it ought, at this juncture, to be determined whether the Ewes are to be fattened with the Lambs, or are to be held on for grass feeding and fattening in the summer months. I advocate both methods as being advisable upon farms of moderate size, where there is a fair proportion of arable and pasture land. I would take half the number of Ewes (those which bring their Lambs earliest) and keep them for the former purpose, and the remaining half I would hold on for the latter.

In carrying out the former plan, the object is to fatten the Ewes at the same time they are suckling their Lambs; and for this purpose, I should recommend precisely the same mode of feeding, both for Ewes and Lambs, as that which has been written upon in detail in my former paper upon the "Management of Forward Ewes and Lambs," and for which I beg to refer the reader to No. 272, page 206, of THE COTTAGE GARDENER. When the method therein described has been carefully carried out, the Lambs will be fit for market at thirteen and fourteen weeks old, and the major portion of the Ewes will be ready likewise, as soon after the Lambs are sold as the weather will admit of their being clipped of their wool.

By the latter mode of management, it is only intended to keep the Ewes in good substantial condition, sufficient for them to maintain and furnish an abundant supply of milk for their Lambs, and to gradually improve their case, in order that they may, when leaving Turnip-feeding, be speedily fattened upon grass. It is, however, a good plan to breed from the Ewes a second season when they have been thus managed. This should, however, be determined by the relative prices between stock Ewes and Mutton; for when stock is higher in proportion than fattened Sheep, they will pay better to breed from again than to fatten upon grass and summer keeping. I have found, for a series of years, that Ewes fattened from shearing-time till Michaelmas will pay about nine shillings per head; whereas the increase in their value when put to the Ram, and kept for stock up to Michaelmas, would, in ordinary seasons, amount to twelve shillings per head.

Nor is this the only advantage to be derived; for the breeding Ewes only require moderate keep, and may be kept in greater numbers by one-third, whereas the fattening Ewes must receive the best summer food upon the farm, and be kept in limited numbers.

To return, however, to the mode of feeding—when the Ewes and Lambs enter upon Turnips it is best for them to begin with common Turnips, which, upon some very dry, sandy, or gravelly soils, may be eaten upon the land uncut if the Ewes' teeth are good; but in case the land becomes very dirty from feeding in wet weather, the Turnips should be cut and given in troughs. The quantity saved by this plan will pay the expense of cutting, in addition to the advantage derived by the animals. Under this system the Ewes receive only Turnips and Hay, and the common varieties of Turnips should always be consumed by the middle of the month of February, after which they should receive Swedes until the end of the Turnip-feeding season. The Lambs must, however, in this case, be fed in the best possible way in accordance with the plan given in detail in a former paper; but I would here state what I believe was there omitted, that a special provision should be made for the Lambs, by the reservation of a quantity of Carrots (where they can be advantageously grown), continuing to feed them upon this root until the early part of April, after which they lose some of their quality, when Mangold may be substituted instead, up to the time of Grass-feeding; indeed, I know of nothing so good to give them, whilst feeding upon grass, as Mangold-wurtzel, cut and placed in troughs, and given alternately with Cake and Peas.

I would here observe upon the great advantage to be derived by feeding Lambs upon White Carrots; for, after several seasons of carefully-conducted experiments upon this subject, I have proved that one-half the quantity of Oil-cake and corn will be saved by their use; that is to say, the Lambs do not, and cannot, eat more than half the quantity of Oil-cake, &c., whilst feeding upon White Carrots, as they do when fed upon Swedish or any variety of Turnips, although they have been allowed a continual supply of roots, and cake, and peas,

ad libitum, in both cases. I must now refer my readers for any further information requisite in Lamb-feeding, and other departments of their management, to my previous paper upon the treatment of Forward Lambs.

JOSEPH BLUNDELL.

THE MAIN CHANCE.

By the Authoress of "My Flowers."

WHAT do my readers understand by the term "main chance?" The believer and the worldly man will totally differ about it; the one will mean treasure hid up in Heaven, dug from the gold-mines of the Gospel; the other, treasures heaped up on earth, toiled for through weary days and anxious nights, too often bringing sorrow as well as gain, and perishing in the using.

I am about to give a sketch of one who sought this last kind of main chance. It is drawn by the able and valuable pen so often busy in the service of his fellow-creatures in these pages; and will, I am sure, interest deeply—I trust, benefit effectually—many a cottage gardener, and many a general reader.

"Godliness with contentment, these be the pillars of felicity," are the words of an eminent modern writer; words which intending emigrants would do well to consider before finally making up their minds to leave the happy homesteads of Old England, for the roughing of the bush, or the excitement of the Australian gold-field. The subject of emigration is fraught with anxious and painful consideration to the Christian philanthropist. That the discovery of gold should have taken place at the same time, in Australia and the southern part of the great Continent of America, is too plainly marked by the finger of God to escape the acknowledgment of any but the avowed infidel, and that, therefore, its results will be for the good of His creatures and the glory of His own name cannot be doubted. Yet it is a distressing thing to witness the rush that has taken place among all classes of society to secure the golden treasures, in spite of risk of voyage, health, and separation from relatives and friends. Some of the readers of THE COTTAGE GARDENER may remember the melancholy but true history of William Green; and I have room to add another instructive lesson from the example of Frederick Jones, who also was in my employ, and the result of whose career has reached me lately by an Australian vessel. Listen, then, ye intending emigrants!

"Frederick Jones was known to me as the son of quiet and respectable people, well to do in their station in life; and when his parents applied to me to engage him to run on errands, and to do other little services which a lad is usually called upon to perform, I did not hesitate in securing his services; for, independent of the good character of the family generally, there was something peculiarly prepossessing in the boy himself. He had a cheerful and manly countenance, with a bright and clear eye, that looked you openly and honestly in the face; nor did his looks deceive, for a steadier, more hard-working, honest lad I never knew, and his obliging and conciliatory manners obtained for him the general good-will of all who knew him. It was with regret, that after remaining with me two years, he left me to follow the business of his father. After leaving me, he continued a regular attendant at the Sunday-school, until, in fact, he nearly reached the estate of manhood, and I looked with much interest on his progress in life. I should, indeed, have been very glad to have taken him apprentice in my own business, but even at this early age he had an eye to what is called "the main chance,"—I mean, the gain of wealth; for, by some means or other, he contracted the notion that his father's trade held out greater prospects of larger wages than my own, and as his parents did not attempt to influence his choice, he was bound to that without hesitation.

"We now come to the eventful period of his life, when, by the lapse of time, he became his own master, and threw off the shackles of his apprenticeship. The news from the gold-diggings arrested his attention, and he determined, at the earliest possible period, to seek in the distant clime

of Australia for that wealth which he thought could not be obtained with sufficient readiness in England. His parents, for some time, opposed his plans, but finding his mind fully made up, they ceased to attempt to influence his choice, and eventually assisted him with the loan of £20,—a large sum for persons in their humble position. The day at last arrived for sailing, and having found a companion who entered fully into his views and feelings, they set sail from Liverpool about eighteen months ago. A letter was received from him from Plymouth, where the vessel touched, and although he had already experienced some of the misery of a sea voyage, it was written in rather good spirits, and he told his mother that they had a clergyman on board, who had preached to the emigrants an impressive sermon on the subject of Abraham's departure at the Lord's command. This letter was full of affectionate leave-taking, and thanks for his parents' assistance; he dealt mournfully on the possibility of not seeing them again, and sent various messages to his younger brothers and sisters.

Months after this rolled away, and no letter came to soothe the anxiety of his parents; and they were almost beginning to be fearful that he had not safely reached his destined port, when the Australian mail brought the long-looked-for epistle. I have only lately read it, so that its contents are fresh and clear upon my memory, and I sincerely wish that its simple narrative was as clearly impressed upon the minds of all intending emigrants, for although evidently written with a view to colour matters as highly as possible, consistently with truth, yet there was such a picture of confusion and hardships to be undergone by the unfortunates who have left the happy shores of England, that would, I am persuaded, make the most sanguine pause before they took a step which would involve great labour and difficulties to attempt to retrace; and, in fact, in most cases, the expence of returning prevents the possibility of doing so."

I must keep the continuation of this interesting tale till my next paper. It is one of instruction and profit, for I am sure, nine people out of ten do not view emigration in its right light. They may *think* they are going out, like Abraham, at the Lord's command, when they are only fleeing, like Jonah, from His face, and casting His words behind them. Abraham obeyed an express command, and went, "not knowing whither;" but people are very often improvident in the good things the Lord gives them; or, greedy of gain, or thirsting after riches, or wearying for something new and exciting, and they go where temptation is offered, where gold abounds, and where God is not known or worshipped! Dear readers! your gains may be less in your Christian home, but they are safe, and peaceful, and honest. Look more to God. Seek His blessing. Ask Him to bless your basket and your store. Turn from your idols. Put away the abominable things which He hates—the false balance, and the bag of deceitful weights. Depend upon it, *our* business is with ourselves; our worldly matters are the Lord's concerns. Oh! if we pray more, we shall prosper more! Let us dig in the Lord's gold-fields, in our closet, with a closed door. That is the way to be rich, holy, happy. Readers! before you follow poor Frederick Jones, try this plan.

POISONOUS SECRETIONS AND ROUP.

FEW facts in physiology are more inexplicable than that of animal poisons, when introduced, by the absorbent vessels, into the system. That a single drop from the poisonous tooth of the adder should, when applied to a wound, forthwith induce such a fearful train of mortal symptoms is, indeed, astounding. The aid of the chemist is sought in vain to shed a single ray of light on the deadly nature of this "leperous distilment." He discovers nothing in the saliva of the rabid animal, or in the poison of the rattlesnake, save the most simple ingredients,—a little water and mucous, combined with minute portions of a simple and innocuous salt, are all that his art and his science can detect!

On the other hand, possibly, some of your readers may now learn with surprise that these very poisons—the poison of the rattlesnake, of the Cobra de Capello, or of the rabid

animal, &c.—may be *swallowed* with entire impunity. The repeated experiments of physiologists have shown that they may be swallowed and introduced into the stomach without their producing any effect whatever! So, also, is it with the matter from the plague sore, and with other vitiated or specific animal secretions of an infecting nature.

These facts are highly interesting in themselves, and must be especially so to those who are impressed with the notion that Roup in fowls is contagious, and that it is communicated from one to another in the manner which Mr. Tegetmeier points out, viz., by swallowing the nasal discharge of diseased birds, for thus observes this excellent writer:—"I imagine that the fetid, purulent discharge from the nostrils of affected birds running into the water, or mixing with soft food, is the usual mode of propagation; and in other cases, it may spread from one fowl picking the incrustated discharge off the beak or feathers of another." The experiments of physiologists with animal poisons and diseased secretions proving that they are swallowed with impunity, at once scatter abroad Mr. Tegetmeier's theory respecting the communication of Roup. Nay, he himself most unhappily does so a week or two before he promulgates it! for, in the very preceding letter, he recounts how of two of his fowls that became affected with Roup, the one, "into the nostrils of which he rubbed the discharge from a dead fowl," and "endeavoured to inoculate," did not show any signs of the disease until a week and some days after the other! Does not the matter of Roup, then, really possess preservative (instead of contagious) powers against the disease? or, at least, defers the attack, or renders it milder, as inoculation for the small pox? For Mr. Tegetmeier tells us, that the chicken not inoculated very soon died; but he does not tell us of the death of the other, but simply that the attack of Roup was long delayed. Surely, surely, then, swallowing the discharge, or pecking it, communicated not the disease, when, in the case of "rubbing in," its approach was delayed! Why, there may be a great discovery here; something more than is dreamt of in the philosophy of contagionists. In all soberness, we cannot but see what tacking about, what saying to-day and unsaying to-morrow is required to bolster up a theory so very questionable—and something more—as that Roup is propagated by contagion.

I, too, have had four cases communicated to me (and I protest against all experiments made by one person as being so liable to error) similar to those of Mr. Tegetmeier's correspondents. On *dissecting* their accounts, I showed to the writers evident sources of doubt, fallacy, and error. I have not, however, gone to the fountain head; and I think it will, at least, be felt that I have completely turned Mr. Tegetmeier's own position, and that by directing his own artillery against it. And his "monster" case, where his own yard of fowls were decimated by Roup (40 having died), and his neighbour's extensive collection escaped, though separated only by "open lath-work," still stands forth in testimony against his hypothesis of contagion, as do numberless similar, though minor examples, when fowls refuse to be infected.

I trust you will do me the favour to find room for the above remarks, which, I assure you, shall be my last on the subject. My chief object was to show that poisonous and vitiated animal secretions are wholly innocuous when introduced by the mouth into the stomach. I conclude with repeating some sentiments of my first letter, viz., there is great danger in the doctrine of contagion, as amateurs will rest satisfied with only removing the diseased fowl; but what produced Roup in that bird, may produce it in all the rest. Seek out the cause, and be strict in your attentions to warmth, pure air, dryness clean water, and to *variety* of healthy food.

F. R. HORNER.

HARDY BORDER PLANTS.

(Continued from page 249.)

ACONITUM VARIEGATUM.

VARIEGATED WOLFSBANE OR MONKSHOOD.

THE *Aconitum versicolor*, before mentioned, and this, the *variegatum*, are a great deal alike; but in this, the blossoms

are pink and white, and very much more loose and spreading than the blossoms of the *versicolor*, which are of a deep blue and white colour, and larger, and much more compactly formed.

This, also, is naturally a taller grower; its stems more slender and straggling in its branches; and its leaves deeper cut, or more rhomboidly cut. The whole plant is quite smooth.

This very desirable species is a native of the South of Europe, and was introduced into this country in the year 1597. It rises from four to five-and-a-half feet high, which makes it a desirable plant for the back or centre rows. It flourishes in any good, common soil, and is readily increased by division of its roots after it puts up its first leaves in the spring. If no increase is required, the old plants may remain in the same spots for almost any number of years, for, should its crown become a little too spreading, it is readily reduced with a fork rather than a spade.

This is one of the tuberous-rooted kinds, supported by an immense mass of root fibres; and when such plants are to remain to flower in the same spots, and expected to do well, the less they are chopped about at the roots the better. I prefer comforting them over the roots, and round their crowns, with a spadeful or two of fresh soil.

T. W.

KENDAL POULTRY EXHIBITION.

THE best proof that the taste for poultry-keeping is extending itself throughout the length and breadth of the land is the increasing numbers of shows. Determined not to be behind their neighbours, the fanciers of Westmoreland last year got up a very creditable Exhibition at Kendal. The second meeting was held on the 22nd, 23rd, and 24th of December last, at the National School-room, in Kendal, and it is admitted on all hands that a very great improvement, due, no doubt, in a great measure, to the spirit of emulation engendered by the previous Exhibition, had taken place in the quality of the stock shown. The number of pens entered were 377. The school-room, in which the Exhibition was held, was rather too small for the purpose, and the consequence was, that part of the pens had to be placed in three tiers, so that the birds in the upper tier were too high to be inspected with advantage, and the height of the pens took away the light in front from those below. This was the only drawback that we could perceive in the management, and we are bound to add that it was one that the committee had not the means of preventing. In one respect, an example was set which the managers of other shows would do well to follow. Three days only were allowed to the show. The birds were received at the doors up to nine, A. M., on the Thursday. By ten o'clock all were in their pens, ready for the judge (Mr. Bond, of Leeds) to commence his labours. These he was able to complete soon after two o'clock, so that the doors were opened to the public by three, and an opportunity was thus allowed to all to inspect the birds the same evening. Now, if one judge can inspect and decide upon the merits of nearly 400 pens of birds, comprised in sixty classes, in four or five hours, there can be no reason why a longer number should not be adjudicated upon in the same space of time by increasing the number of judges. By such means a private view, at least to subscribers, might be afforded in the evening of the first day, and all excuse for running the show beyond a third day removed. The birds would thus leave their homes so as to be received at the place of exhibition on the morning of one day; they would remain there during that and the two succeeding days; and, by the employment of a sufficient force, they might all be easily put upon the rail on the third night, so as to reach their own walks on the day following. The only attention required in this respect, at Kendal, is that the first day should be Tuesday or Wednesday, instead of Thursday, so that the fowls should not have to be despatched on the Saturday night. The managers, and their indefatigable honorary secretary, Mr. James Gillard, will, we feel assured, excuse us for giving this hint for improvement where there was so much to commend.

In noticing the various classes according to their order

in the catalogue, the *Spanish* first claim our attention, and they were, young and old, most creditable to the good folks of Kendal, who carried off all the honours in both classes. The *Dorkings* were, perhaps, even better classes, the prize birds in the chicken class being very good indeed. The *Buff Cochins* presented nothing very particular in the adult class, with the exception of the first prize birds. Among the chickens some creditable specimens were exhibited, and the same remark applies to the Whites. In the dark variety, the first prizes were withheld, but a good pen of Black chickens obtained and deserved a first prize in their class. The *Game* classes were exceedingly good, and we repeat a remark which we have had occasion to make before, that we are glad to see these old English fowls cultivated, even though they are no longer required for the purpose of the cock-pit. The *Hamburgs* and *Polands* afforded no subject of especial remark, if we except a good pen of Golden *Polands*, and one of Blacks, each of which carried off a first prize in its class. Of the *Bantams*, the Blacks were the best. The *Geese* were not particularly good, and the *Ducks* were said not to have been equal to those shown the previous year. The *Turkies* were a good class. We append the prize list as usual.

SPANISH.

Class 1.—Cock and two Hens. 2. First prize, Mr. R. B. Parkinson, Kendal. 4. Second prize, G. A. Gelderd, Esq., Akrigg End, Kendal. Class 2.—Cock and two Pullets, chickens of 1853. 17. First prize, Mr. R. B. Parkinson. 24. Second prize, Mr. William Whitwell, jun., Tolson Hall.

DORKING (Single-combed).

Class 3.—Cock and two Hens. 26. First prize, Henry Ambler, Esq., Wackinson Hall, Halifax. Age, one year eight months. 29. Second prize, G. A. Gelderd, Esq. Age, three years six months. Class 4.—Cock and two Pullets, chickens of 1853. 53. First prize, Thos. Ullock, Esq., Bowness. Age, eight months. 54. Second prize, Thos. Ullock, Esq. Age, cock, five months eight days; pullets, eight months.

DORKING (Double or Rose-combed).

Class 5.—Cock and two Hens. 63. Second prize, Mr. Thompson, Hynig. Age, one year six months. First prize not awarded.

DORKING (White).

Class 7.—Cock and two Hens. 71. First prize, Mr. Jas. Rookes. Age, two years seven months. Second prize not awarded.

COCHIN-CHINA (Cinnamon and Buff).

Class 9.—Cock and two Hens. 74. First prize, Henry Ambler, Esq. Age, one year seven months. 75. Second prize, G. A. Gelderd, Esq. Age, one year six months. Class 10.—Cock and two Pullets, chickens of 1853. 112. First prize, Mr. George Gibson. Age, nine months. 86. Second prize, Henry Ambler, Esq. Age, six months.

COCHIN-CHINA (Brown and Partridge-feathered).

Class 11.—Cock and two Hens. 116. Second prize, W. Wanklyn, Esq. Age, cock, one year eleven months; hens, one year eight months. First prize not awarded. Class 12.—Cock and two Pullets, chickens of 1853. 125. Second prize, Wm. Wanklyn, Esq. Age, cock, nine months; pullets, eight months. First prize not awarded.

COCHIN-CHINA (White).

Class 14.—Cock and two Pullets, chickens of 1853. 128. First prize, Edward Calvert, Esq., Warwick Bridge, Carlisle. Blue mark on the crest. Age, eight months one week. 129. Second prize, Edward Calvert, Esq. No mark on the crest. Age, eight months.

COCHIN-CHINA (Black).

Class 16.—Cock and two Pullets, chickens of 1853. 133. First prize, W. Wanklyn, Esq. Age, nine months.

GAME FOWLS (White and Piles).

Class 19.—Cock and two Hens. 140. First prize, H. W. Heaton, Esq. Age, one year. 137. Second prize, Mr. W. Wilkinson, Brigsteer. Age, one year six months. Class 20.—Cock and two Pullets, chickens of 1853. 142. First prize, Mr. Frank Atkinson. Age, six months. 145. Second prize, Mr. John Thackeray, Hawkshead Hall. Age, eight months one week.

GAME FOWLS (Black-breasted and other Reds).

Class 21.—Cock and two Hens. 162. First prize, Mr. George Banks. Age, one year seven months. 150. Second prize, Mr. James Thompson. Age, one year six months. Class 22.—Cock and two Pullets, chickens of 1853. 180. First prize, H. W. Heaton, Esq. Age, eight months. 178. Second prize, Daniel Leeming, Esq. Age, six months.

GAME FOWL (Best of any other variety).

Class 23.—Cock and two Hens. 185. First prize, Henry Ambler, Esq. Age, one year eight months. 188. Second prize, Mr. W. Wilkinson. Age, two years five months. Class 24.—Cock and two Pullets, chickens of 1853. 201. First prize, H. W. Heaton, Esq. Duckwings. Age, eight months. 200. Second prize, Daniel Leeming, Esq. Age, six months.

GOLDEN-PENCILLED HAMBURGH.

Class 26.—Cock and two Pullets, chickens of 1853. 203. Second prize, H. W. Heaton, Esq. Age, six months.

GOLDEN-SPANGLED HAMBURGH.

Class 27.—Cock and two Hens. 205. Second prize, Mr. W. W.

Ruttlidge. Age, one year six months. Class 28.—Cock and two Pullets, chickens of 1853. 225. First prize, Mr. H. W. Heaton. Age, eight months. 217. Second prize, Mr. James Rookes. Age, seven months.

SILVER-PENCILLED HAMBURGH.

Class 29.—Cock and two Hens. 231. Second prize, Mr. George Gibson. Age, one year eight months. First prize not awarded. Class 30.—Cock and two Pullets, chickens of 1853. 235. First prize, Mr. Christopher Brown. Age, eight months. 232. Second prize, G. A. Gelderd, Esq. Age, six months two weeks.

SILVER-SPANGLED HAMBURGH.

Class 31.—Cock and two Hens. 243. First prize, Daniel Leeming, Esq. Age, one year six months. 245. Second prize, Mr. Thomas Robinson. Age, one year six months. Class 32.—Cock and two Pullets, chickens of 1853. 249. First prize, Daniel Leeming, Esq. Age, six months. 248. Second prize, Daniel Leeming, Esq. Age, six months.

POLAND FOWL (Black, with White Crests).

Class 33.—Cock and two Hens. 256. First prize, Joseph Conyers, Esq. Age, one year six months. Class 34.—Cock and two Pullets, chickens of 1853. 257. Second prize, G. A. Gelderd, Esq. Age, six months two weeks.

POLAND FOWL (Golden).

Class 35.—Cock and two Hens. 259. First prize, Joseph Conyers, Esq. Age, two years seven months. 258. Second prize, G. A. Gelderd, Esq. Age, two years six months. Class 36.—Cock and two Pullets, chickens of 1853. 260. Second prize, G. A. Gelderd, Esq. Age, five months two weeks.

POLAND FOWL (Silver).

Class 37.—Cock and two Hens. 261. Second prize, T. K. Atkinson, Esq., Cardew Lodge, near Carlisle. Age, two years six months. Class 38.—Cock and two Pullets, chickens of 1853. 262. Second prize, T. K. Atkinson, Esq. Age, seven months.

BANTAMS (Gold-laced or Pencilled).

Class 40.—Cock and two Pullets, chickens of 1853. 264. First prize, W. Wanklyn, Esq. Age, eight months. 263. Second prize, H. W. Heaton, Esq. Age, nine months.

BANTAMS (Silver-laced or Pencilled).

Class 41.—Cock and two Hens. 265. Second prize, H. W. Heaton, Esq. Age, cock, two years; hens, one year. Class 42.—Cock and two Pullets, chickens of 1853. 266. Second prize, Mr. John Waugh. Age, six months.

BANTAMS (Black).

Class 43.—Cock and two Hens. 276. First prize, Joseph Conyers, Esq. Age, three years. 269. H. W. Heaton, Esq. Age, one year. Class 44.—Cock and two Pullets, chickens of 1853. 272. First prize, H. W. Heaton, Esq. Age, nine months. 273. Second prize, Jos. Wilson, Esq. Age, ten months.

GEESE.

Class 49.—Best Gander and one Goose. 288. First prize, Mr. John Stamper. Age, seven months two weeks. 287. Second prize, Mr. John Stamper, Newton, Penrith. Age, seven months two weeks.

DUCKS.

Class 50.—Best white Aylesbury Drake and two Ducks. 298. First prize, Mr. Joseph Morton. Age, five months. 302. Second prize, Mr. Henry Lickharow, Kendal. Age, six months.

DUCKS.

Class 51.—Best Rouen Drake and two Ducks. 318. First prize, Henry Ambler, Esq. Age, one year six months. 317. Second prize, Mr. R. B. Parkinson. Age, six months. Class 52.—Best Drake and two Ducks of any other variety. 323. Second prize, G. A. Gelderd, Esq. Call Ducks. Age, seven months. 327. Jas. Bousfield, Esq. Age, seven months two weeks. 330. Second prize, Mr. Thos. Robinson. Age, two years seven months.

TURKEYS.

Class 53.—Best Turkey Cock and one Hen. 341. First prize, Mr. W. Whitwell, sen. Age, eight months. 335. Second prize, Jas. Yeates, Esq. Age, nine months.

GUINEA FOWL.

Class 54.—For the best pair. 347. First prize, G. A. Gelderd, Esq. Age, one year six months. 349. Second prize, Mr. Jas. Rookes. Age, one year seven months.

ATOMS FOR THE TIMES.

How are histories made up? Let those who write them answer, and they will, doubtless, say, from scattered facts—things done and given off to the world, claiming small consideration in themselves possibly at the time, but to become largely valuable for the compiler as atoms of knowledge, illustrating the national mind and practical intelligence of the day. Let this be my excuse, then, for wielding my grey goose quill once again, for who can tell but a particle for improvement may be imparted towards a systematic whole for the future?

I intend, in the present paper, to describe a few seasonable facts resulting from my own experience, conformable to what Mr. Errington wrote at page 156 about renovating old gardens. The first instance occurred nine years since

with an old garden (a deep loam, with its surface black from long culture), which came into occupation as a conciliatory conclusion to letting some land; it was willingly given up by the lessee as being a patch of ground comparatively worthless, and which, indeed, would scarcely grow turnips larger than hen's eggs: we shall see.

Firstly, the hedge was "plashed" around, and a dressing of road-scrappings hauled on, and spread at the rate of sixty loads to the acre. It was then bastard-trenched two feet deep, the *crumbs* between the spits only being shovelled upon the surface. This trenching affair caused a sensation rather, though little was said to me upon the subject, with the exception of one man, who evidently considered me as all in the wrong. Poor fellow! his build was Herenlean: he was once "P'th'local," and his bearing was upright as a ramrod. I believe he has never to this day forgiven me about that trenching; the "back aches," the "wet shirts," and the "right down hard work," which he was sure to greet me with, and as surely to meet with my pity, was something to lament and laugh about at the same time. Once, though, a terrible row happened. James did not go about his work quite to my satisfaction, and upon my intimation of the same, it caused him to dash down his spade, and boldly confess that he "knew how to trench before I was born." I could only appease his offended dignity by assuring him, that the individual who taught me to trench was a person much younger than myself. What time the horse, the cows, and the pigs did not engage him, he employed during the winter about this process, and the hardship was more in the breach than the endurance. A top-dressing of wood-ashes was applied, and seeds of the *White Belgian Carrot*, and of the *Yellow Globe*, and *Long Red Mangold Wurtzels*, were sown in drills,—the first twenty-four, and the latter thirty inches apart, during the beginning of April: the Carrots becoming finally thinned-out to nine inches, the Wurtzels to eighteen inches, and I shall never forget the splendid crops as a result. I could have run hard upon the heels of a prize with samples of each of those roots at any show in the kingdom. The Wurtzels were consumed by the cows and pigs, a part of the Carrots by the horse, and thirty cwt. were sold as "wonderments"—quite a new feature—in Ludlow market, at 5s. per cwt.

My second experience refers to the garden now in occupation. It has been under cultivation for culinary vegetables upwards of two hundred years, and for a long time had lain under the bane of being a piece of ground occasioning more expense than it was worth. The miserable specimens of crops, with the altogether, that greeted me on my first introduction after what I had been led to expect, was something lugubrious in the extreme, and would certainly have disheartened any person not accustomed to look beyond the surface of things. With me, to probe the subsoil was an object for instant operation. I found it all right, not primitive, but it had never been disturbed since the garden was made; below the depth of thirty inches a wet plastic clay presented itself, which made me decide at once for drains. It is now six winters since, reckoning with the present, that a re-arrangement of the whole thing took place,—a mere sow's ear" affair; but the ground was drained, and sorted, plain trenching I cannot call it, for what with a new fruit border, shifting walks, and so on, the whole body of the soil became removed into a new position; care was taken, however, to keep the subsoil down as much as possible. Several year's collection of rotted debris—famous as a preserve for rats—was cleared out of a back yard, and added as the completion, a planting went on, and this was all the manure afforded.

Just before sowing-time, soot and salt was applied as a top-dressing, and the greater part of the ground became cropped with Potatoes; the result gave over two hundred sacks for the acre, and the bountiful produce the soil has since continued to yield, coupled with the vigorous health of the fruit-trees and ornamental shrubs, shows plainly the principle upon which old gardens can be renovated; and, let me add, all holdings whatsoever, be they great or small, agricultural or horticultural. For my own part, rather than allow the expense about a want of dung to distress me, I would break up the most uncongenial subsoil as a means for far more recompense.

Practice and science will, it is to be hoped, soon join

hand in hand never more to be parted, and then prejudice and ignorance must give way, for, of all that has been done and written, from Colmanella down to Mr. Mechi, we still really appear but just stepping upon the threshold of a thorough knowledge of the capabilities of the soil. Comparing notes with what has been achieved for its sister sciences, we need only consider the advancements effected in the breeds of animals, and the steady improvements from good to better in the floral, fruit, vegetable, and cereal products, to become aware that a laxity—and this is the more surprising, the land being a great first cause—prevails towards an equal consideration for its merits. When a soil neglected, capable only of yielding a beggarly produce one year, can, by merely breaking-up the subsoil, and with a trifling extraneous aid be made to yield enormous crops the next year, the question naturally intrudes, How is it that this process is so little entered upon or thought of? There is nothing abstruse about the matter practically, although, abstractedly, it points to the laboratory of the chemist and the way of science. The answer appears to resolve itself—The man who breeds an improved Short-horn, or introduces a Sebright Bantam, raises a superior description of fruit, and improves the properties of grain, &c., seldom achieved these things by chance; a vast amount of study and perseverance have been required to form the animal, and bring the produce to what we now find them, and generations have been required to do it in; yet still the work goes on, and the inquiry at last arises—What their original parents? and whence the wheat and barley?

An experiment with Barley, by-the-by, just forces itself upon my recollection. At page 268 of the last volume, I related the circumstance, perhaps some of my readers may feel interested if I explain the result. Personally curious, and when the scythe was in full operation upon its namesake, I again took train, and the 22nd of August found me once more, note-book in hand, at the Oxford Botanic Gardens; it would have been as well had I deferred my visit until somewhat later, for the Barley, being shaded by the trees from the morning sun, was not so ripe as I thought to find it. According to my judgment this was the state of the boxes—No. 1, red chalk; No. 4, common earth; and No. 7, Herefordshire iron and stone; showed their crops very nearly equal in straw and grain. No. 1 (possibly attributable to its situation) was the ripest, and its corn the finest. No. 2, oolite; No. 3, Brighton chalk; and No. 5, sand; claimed the second degree—a very moderate result. No. 6, Skiddaw slate, and No. 8, a slate, were failures—plucked decidedly. Probably many other persons took an equal interest in this experiment with myself. It is a step in the right direction; and the more public trials we meet with of this sort, the quicker shall we be enabled to form our ideas for practical purposes. It would be well if such experiments were carried out plurally in different parts of the country at the same time, and conclusions compared.

UPWARDS AND ONWARDS.

LETTER FROM AN EMIGRANT GARDENER IN SOUTH AUSTRALIA.

Two or three years since, the writer of the following letter lived as gardener with a gentleman in Ipswich. He left his situation with his wife, and, I believe, two children, to settle in Australia. Subsequently, his father, who was a working gardener, also joined him, taking over the rest of the family. The letter was sent to a cottager of his acquaintance residing in my parish, and on its being shown to me, I obtained his permission to copy it for insertion in the "COTTAGE GARDENER," thinking that it would interest not only other gardeners but your readers in general.

P. S., Rushmere.

"Pastures Farm, South Australia.

"April, 1853.

"Dear Friend.—An opportunity now offers itself for me to send a few lines as you wished me to do so in a letter I received from you a short time since, and for which I am obliged. I have been living as gardener to Captain Sturt, up to November, 1851, when I left him, and had a liberal offer made me to take a piece of land, which I accepted, and

here I am in a comfortable house and a good piece of ground (6 acres); my crops have paid well considering, for the first season, and it has been the most expensive one I shall have, having had every thing to buy, my land to fence in, house, stable &c., to build. I never intend to work for a master again, although masters here dare not say any thing to their men. I mean to tell you, this is a place for a working man. I hail the day with pleasure that I landed in this my adopted country, for here a man may feel what he can never feel in England, and that is independence. I wish I had left before; I like the Colony; true, there are three months in the year that are not pleasant, as the heat is great, but not oppressive; the other nine are equal to May or June with you, and things grow well. Grapes are as fine as in any part of the world; the Muscats ripen here in the open air equal to any thing I ever saw in England; and I have seen bunches of other kinds which weigh as much as 27 lbs. and as black as jet, with a good bloom. Peaches, and all European fruits, do quite as well as do many of the Tropical kinds. As you wish to know a little about the animals &c., I will tell you of a few; but there are so many that it would occupy too much room here to mention all. We have the Kangaroo Rat; several sorts of the Kangaroo which is hunted by dogs called Kangaroo Dogs. There is the Wild Dog in great numbers; these are hunted by fox-hounds; the Opossum; the native Cats; Wallabeyes of many kinds. Of birds there are a great collection; the largest is the Emu, standing five or six feet high, and runs with great speed; the Turkey, large and good eating; Eagles, Hawks of many kinds; and some very large and handsome Bitterns, several sorts—the handsomest is the night Bittern; Robins, five varieties. I have seen Duck and Teal in great numbers; I shot eighteen one evening last week, in about an hour, not five minutes walk from my house. Quails abound by thousands, and the sport is equal to Partridge shooting; they are like the English bird, only about half the size; Swans and Geese are plentiful in winter. The Parrots are the handsomest of all the feathered tribes; there are many varieties, large and small; the smallest is the Budgaraga or Sbell or Love Parrot. I have caught twelve and fourteen pounds worth in one day. This is a trade I have taken up, and a very good one it is; I use clap nets. There are hundreds of other birds which I cannot name; but no good songsters. The Laughing Jackass is a curious bird; you would think some one was laughing at you. All the birds here halloo and whistle. I have not as yet had time to get a collection. We have several kinds of Snakes—black, brown, silver, carpet, whip, and others; but the worst of all is the deaf Adder; they are only found by the coast; plenty of Lizzards and Guanas; these are harmless and very handsome. Spiders of all colours; there is one kind that builds a door with strong hinges by which it opens and shuts; you have to ply it hard with a knife before the spider lets go. I earned six pounds the other day in getting their nests to go to England. We have the Centipede, the Tarantula, Scorpion, and thousands of insects which I know nothing about. Very few Butterflies and Moths, and their colours not brilliant. Nothing annoys us so much as the flies, and these only in summer. We have few Mosquitos; they are mostly near water. As soon as I can I intend to collect, but as labour is and has been scarce, and wages are high, I have had to keep close to work. I employ one hand, and I cannot get a labouring man under seven or ten shillings per day; mechanics earn from twelve to sixteen shillings. If a man wants to better his condition let him come here, and in two or three years he may have a piece of land of his own. I was sorry hear of the death of Mr. J. R—; it must have been a great loss to many, as there were but few masters like him.

“There have been thousands come to these colonies. The Gold diggings are yielding well, and numbers have made fortunes at them, but very many have done no good; I went, but did not stay. My father and brothers had a long spell at it but did not succeed, except my brother Alfred, who has done better and is there still. EDWIN SMYTH.”

BEE-KEEPING FOR COTTAGERS.

(Continued from page 249.)

SECTION 2.—APPARATUS REQUIRED IN BEE-KEEPING.

WE hope none of our readers will be frightened at the long list of apparatus that we shall mention: it by no means follows that every article will be absolutely necessary; or, if necessary, need be made as we describe; certain objects have to be attained, and we describe such articles as we conceive to be useful in attaining such objects; if they can be attained in any more simple mode, by all means let it be done. A bee-keeper ought to be prepared for every contingency, and it may be taken for granted that the little extra trouble that will be required to make one's set of apparatus *complete* will be well bestowed.

Hives.—The oldest bee-keepers are at present undecided whether straw or wooden hives are to be preferred. The former, from their cheapness, will generally be preferred by cottagers. All stock hives should be of the same size, viz:—thirteen inches in diameter, that is, across, and eight inches in depth, both inside measure; they should be straight in the sides, and quite flat on the top; a hole, four inches in diameter, should be left in the top; this may be covered over (not fitted) with a piece of inch deal about six inches square, or a piece of straw-work like the hive, about six inches in diameter. If the entrance be made in the hive it may be two inches wide, and the depth of the lowest round of straw; it is better, however, to have the entrance in the floor-board for convenience in operating. (See *Floor-boards*). Three or four spare hives should always be kept ready for use, as there is no knowing what emergencies may arise.

Top Hives.—For each stock-hive, you should have two small super or top hives, at least. These should be the same in form as the stock-hives, one smaller than the other, but both smaller than the stocks; the smaller need not have a hole at the top. One may be ten inches across, by seven inches deep; and the other eight inches across, by six inches deep. Each should be furnished with a small glass window about three inches square. Each window may be covered over by a thick piece of baize, or a piece of linen, three or four times doubled, tucked into the bindings of the hive over the window, and secured from being blown about by the wind by a piece of twine at its lower end, or by a piece of deal the exact size of, and just thick enough to fill up the opening in which the glass is fixed, and so exclude the light; this deal shutter can be fixed in its place by a thin piece of cane laid across it, having its ends tucked into the bindings of the hive; all light must, in some way or other, be carefully shut out. It will be prudent to have a good stock of super-hives always ready, as in fine honey getting weather those on the stock-hives will be quickly filled, and must be replaced by empty ones.

Wooden Hives.—Should it be wished to try wooden hives they may be made of full inch deal, eleven inches square, by nine inches deep, both inside measure, with a hole three inches square at the top, and windows five inches square in two of the sides: these windows should be covered with pieces of zinc rather larger than the windows themselves, and made to slide over the side the hive, between two rows of tacks set pretty closely together in the rows. Small wooden boxes may be used on the top of wooden hives in the same manner as straw supers are used on straw hives; they may be made of thinner wood than the stock-hives, and should have as large windows (to be covered as before) as can be safely made in them.

Glasses.—If it be wished, glasses may be used instead of top-hives; in that case, the top-hives will do as coverings for the glasses, for glasses must be covered and kept warm, or the bees will not work in them. They should even be wrapped round with tow, or a bit of old druggot, or blanket, before being covered, or the bees will, except in very warm weather, go down in the night, and not resume work till late the next day: it is as well to form this druggot or blanket into caps fitting loosely over the glasses: they will not only be more easily removed and replaced when it is wished to examine the glasses, but neatness will be thereby secured. It is very interesting to watch, and, therefore, desirable to have one or two hives worked with glasses; it must be remembered, however, that bees do not work so well in glass as in straw. As the management of glasses and top-hives

is the same (except as regards warmth), no more will be said on the subject of glasses specially.

Floor-boards.—These should be of the same shape as and about two inches broader than the lower part of the stock-hive, and may be made of any stout stuff not less than an inch in thickness. Two bits of wood or clips about nine inches long, two deep, and one broad, should be screwed underneath them across the grain. These clips prevent the floor-board twisting, and should be about six inches apart so as to drop over the head of the pedestal, or bee-stand, which will be next described; by this means the whole is kept firm. It is advisable to nail or screw a thin piece of deal ($\frac{1}{2}$ -inch stuff), the exact size of the lower part of the stock-hive, on the upper surface of the floor-board, in such manner that the grains may run in exactly opposite directions; the grain of the thin piece, in fact, running in the same direction as the clips. In this thin piece, or if the thin piece be not used, then in the floor-board itself, the entrance, which should be four or five inches wide, and half-an-inch deep, ought to be formed. To do this, make two saw cuts just so far apart as is required for the width of the entrance, and running in the same direction as the clips from the edge towards the centre of the floor-board. Let this cut be rather more than half-an-inch deep at the edge, and go off to nothing at the middle; then pare all the wood between these cuts away, and you have a slope leading up into the hive; then neatly fix another small piece of wood in front of this slope, where the bees can alight, and the floor-board is complete. An entrance in the hive itself (which not only helps to destroy the hive, but is, as already mentioned, greatly in the way in operating) is, by this means, rendered unnecessary. It is always advisable to bevel off the edges of the floor-board, to assist the passing off of any drip. Stone or slate for floors must not be thought of for an instant: such materials are far too cold. There should always be extra floor-boards ready for use.

Pedestals, or Bee-stands.—Each hive should have its separate pedestal, and in fixing them an eye should be given to future operations. There should, if possible, be room to get behind them. They may be placed in two's at such a distance apart that the floor-boards, when placed upon them, may be about three inches apart. Room should be left between each set of two to fix a third, if necessary. A pedestal of unbarked fir or larch, about five or six inches thick, looks as neat as anything. It should stand about a foot or fifteen inches above the ground, and be sunk at least two feet into it; the earth must then be rammed down hard all round it. It is as well to give the pedestal the slightest possible inclination forwards, that any moisture which may be condensed upon the combs and may run down to the floor-board may be thrown off at the hive entrance.

Before it is fixed, a cross-piece, barely six inches broad, must be nailed firmly to the head of it, over which the clips of the floor-board are to drop. Should it be difficult to procure such stands as these, old beer barrels, or pieces of stout wood six inches in breadth and fixed on three stout legs, milking-stool fashion, or anything that can be firmly fixed will do as well—neatness, however, is always desirable. The cross pieces, in fixing the pedestals, must be made to face forwards, in order that the entrances in the floor-boards may come into the right position.

(To be continued.)

TO CORRESPONDENTS.

ICE-WATER (J. L.).—We do not know of any plan by which you could keep clean ice along with ice that is not clean. If you were to put a quantity of clean ice in a metal or wooden case, and bury it in the centre of the dirty ice, it would be a great waste, as a leaf or a twig among it will cause it to waste; besides, the melting of the dirty ice would soon impregnate the purer article, unless the containing vessel was made of zinc and water-tight. If you could keep it so, and your master put a lump or two of it into his drinking water, you would soon have to look out for another master who valued his health more, for there is nothing more unwholesome to drink than ice-water, unless it be the doctored ware in the cellar of a beer-house, and that never gives the threat disease called goitre, which ice-water is apt to do sooner or later. If your master must have iced-water, the cheapest way by far, is to make new clean ice for him two or three times a week, from water drawn from his

own pump. How that is done we mean to show very soon, and we are glad of your letter to remind us to warn our readers against using ice-water even from the purest source. To make new ice every morning in July is a much less costly process than to keep old ice in this country.

BIRMINGHAM POULTRY SHOW.—The sales in the Poultry Department have been very numerous, the majority of the pens having been disposed of—a fact which may be attributed to the moderate prices most of the exhibitors placed upon the birds which there was no intention of retaining by the naming in the certificates of a prohibitory one. One of the lots sold was the pen of the yet scarce Bramah Pouter, sent by Prince Albert. The price was £50; but we believe Mr. John Baily, the eminent and respected poultry dealer, of London, received £110 for a pair of fine specimens of this variety. These sums are by no means so fabulous or absurd as some unreflecting persons may imagine, when we bear in mind that they are given for a desirable addition to the ordinary kinds of domestic poultry, which, for some time to come, must be very scarce in this country, and eagerly sought after. Fowls, under ordinarily favourable circumstances, are, we know, prolific, and with the number of chickens which, with skilful management, may be obtained from three or four hens, in the course of a season, a spirited breeder may reasonably expect to repay himself such outlays as those we have mentioned. Mr. Andrews, of Dorchester, we believe, sold a pen of Cochins-China fowls for £50, and some other pens sold for the same sum; £10, £30, and £20 being given in tolerably numerous cases. The bulk of the transfers took place on the first day, when they amounted to £1,125 6s.; on Wednesday, to £295 13s.; on Thursday, to £136 6s.; and on Friday, to £123 15s.; the total being £1,681.—(*Midland Counties Herald*.) We have many complaints of pens of birds being sold before any visitor could look at them. Two hours should be allowed for inspection before the sale office is opened.

ADAM'S OAK.—P. writes to us as follows: "Between Hemsworth and Great Houghton is a famous old Oak, called 'Adam Oak'; when the sun favours us again I hope to send you a photograph of it, to be engraved in *THE COTTAGE GARDENER*. Also, I should be glad if any of your readers would favour me with any well authenticated history, legend, &c., relating to it. It is situated on Briery Common, and by its side once stood 'Eve,' another Oak, which has been cut down to make a road across the Common!—at least, so I am told." Can any of our readers give the desired information?

ROUP CONTAGIOUS.—Mrs. C. writes as follows:—"I have some valuable poultry, purchased from Capt. Hornby and others, and a fortnight ago I purchased a few Shanghaes in this neighbourhood; the evening after they were bought, I observed something remarkable about the fowls, especially one which I examined and removed. I gathered from *The Poultry Book* it must be Roup. I therefore removed them all, and sent my best stock a few miles in the country to board. I am fully aware that they all drank together, and it is evident to me that in no other way could the contagion have spread, for they did not run together, only met in the yard. The common fowls I kept at home have nearly all taken it, and upwards of thirty I had killed. My question on this head is—When may I safely venture to have my best stock home, without hazard to any that have not been infected by it? One question more, if you will allow me. Our Poultry Show is fixed for next week. If the nostrils and eyes of my best fowls should be dry, would it be any risk to cage them together during those two days?" We should not hesitate to have the birds back to the yard if it was purified by chloride of lime, &c., as recommended by us recently; and the yard allowed to remain empty for a week or two. Nothing would justify exhibiting the birds for some months, or until quite well.

SPANISH FOWLS EGGS (T. F.).—We should put them under a Game hen rather than under a Dorking hen. *Poultry Houses* are treated of most copiously in the first number of *The Poultry Book*.

NORWICH SNOW.—Mr. Playford says we were wrong in considering that he alluded to Mr. Cattling when commenting upon the award of the Prizes, "because he was not there; and if he had been, is sure he would not have done it." So we said.

GOLDEN HAMBOURG (S. B.).—If there is any difference, the *Spangled* are rather harder than the *Penicilled*. The latter, however, are the best layers. Write to any one who has taken prizes for them, and state what you require.

TURKEYS (A Worcestershire Lady).—We think from four to six hens are the best numbers for one cock, and we prefer the smaller number.

LAME SHANGHAE COCKEREL (W. Windley).—What kind of lameness is it? Is it a limping with one leg, or a want of power to move it; or is it a spasmodic lifting up of the legs higher than usual when walking?

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-six years, the average highest and lowest temperatures of these days are 42° and 31.3° respectively. The greatest heat, 56°, occurred on the 14th in 1849; and the lowest cold, 4°, on the 14th in 1833. During the period 104 days were fine, and on 85 rain fell.

NEW PLANTS.

METTERNICHA PRINCIPIS (*Princely Metternichia*).

At first sight this plant has the appearance of a loosely-flowered *Azalea indica*, but it belongs to the Natural Order of Nightshades, and to Pentandria Monogynia of Linnaeus, being grouped in the Natural System with *Sessea* and *Cestrum*. It is in our stoves an evergreen shrub of about three feet high. It was named by M. Mikan, its discoverer, in honour of the Austrian Prince Metternich-Winneburg. Its flowers are white, with greenish tubes, and "powerfully and deliciously fragrant." It blooms during August in our stoves.—(*Botanical Magazine*, t. 4747.) Some authorities have stated, that in its native country it attains the height of twenty-five feet, but Mr. Gardiner, curator of the Ceylon Botanical Garden, and who had seen it growing about Rio Janeiro, says it is a shrub smaller than *Stiflia chrysantha*, the average stature of which is eleven feet. He justly describes the flower as "not unlike those of a *Datura*."

ABIES BRACTEATA (*Bracted Silver Fir*).

We are so utilitarian that we rejoice over the introduction of a new hardy timber-tree much more than over the appearance among us of the most beautiful new flowers. Right glad are we, therefore, to find that this noble example of the true Pines is now settled among us, and may be purchased of Messrs. Veitch. It was introduced by their

able and successful collector, Mr. Lobb, who we congratulate upon having returned to England in health and safety. It is a native of California, where it was first discovered by Dr. Coulter, and subsequently by Douglas, in latitude 36°, and at an elevation of 6,000 feet. Mr. Lobb thus describes it:—

"This beautiful and singular tree forms here (he writes from the Californian forests) the most conspicuous ornament of the arborescent vegetation. On the western slopes, towards the sea, it occupies the deep ravines, and attains the height of 120 to 150 feet, and from one to two feet in diameter: the trunk is as straight as an arrow; the lower branches decumbent; the branches above are numerous, short, and thickly set, forming a long tapering pyramid or spire, which gives to the tree that peculiar appearance which is not seen in any other kinds of the *Pinus* tribe. When standing far apart, and clear from the surrounding trees, the lower branches frequently reach the ground, and not a portion of the trunk is seen from the base to the top.

"Along the summit of the central ridges, and about the highest peaks, in the most exposed and coldest places imaginable, where no other Pine makes its appearance, it stands the severity of the climate without the slightest perceptible injury, growing in slaty rubbish, which to all appearance is incapable of supporting vegetation. In such situations it becomes stunted and bushy; but even there the foliage maintains the same beautiful dark green colour, and when seen at a distance it appears more like a handsomely-grown Cedar than a Pine. No doubt it is one of the hardiest trees of the Californian vegetation, and is equally well adapted for clothing the mountain-tops as the sheltered valley.

"The cones, too, are quite as singular as the growth of the tree is beautiful; when fully developed, the scales, as well as the long leaf-like bracts, are covered with globules of thin transparent resin, presenting to the eye a curious and striking object. Douglas was mistaken in saying that this Fir does not occur below 6000 feet of elevation; on the contrary, it is found as low as 3000 feet, where it meets *Taxodium sempervirens*."—Perhaps the introduction of no *Conifera*, not even that of the Deodar, has excited a more lively interest in horticulture and arboriculture than that of the present species, with its porcupine-like fruits.—(*Botanical Magazine*, t. 4740.)

Mr. Lobb is believed to have also introduced another new Conifer from California, for which Dr. Lindley has proposed the name *Wellingtonia gigantea*. This, however, is premature, for it is not yet clear that it has generic characters sufficiently distinct to separate it from *Sequoia*. In the *Gardeners' Chronicle*, Mr. Lobb thus speaks of this "Giant of the Forest"—

"This magnificent evergreen tree, from its extraordinary height and large dimensions, may be termed the monarch of the Californian forest. It inhabits a solitary district on the elevated slopes of the Sierra Nevada, near the head waters of the Stanislan and San Antonio rivers in lat. 38° N., long. 120° 10' W., at an elevation of 5000 feet from the level of the sea. From 80 to 90 trees exist, all within the circuit of a mile, and these varying from 250 feet to 320 feet in height and from 10 to 20 feet in diameter. Their manner of growth is much like *Sequoia* (*Taxodium*) *sempervirens*, some are solitary, some are in pairs, while some,

and not unfrequently, stand three and four together. A tree recently felled measured about 300 feet in length, with a diameter, including bark, 29 feet 2 inches, at 5 feet from the ground; at 18 feet from the ground it was 14 feet 6 inches through; at 100 feet from the ground, 14 feet; and at 200 feet from the ground, 5 feet 5 inches. The bark is of a pale cinnamon-brown, and from 12 to 15 inches in thickness. The branchlets are round, somewhat pendent, and resembling a Cypress or Juniper. The leaves are pale grass-green; those of the young trees are spreading, with a sharp acuminate point. The cones are about $2\frac{1}{2}$ inches long, and 2 inches across at the thickest part. The trunk of the tree

in question was perfectly solid, from the sap-wood to the centre; and judging from the number of concentric rings, its age has been estimated at 3000 years. The wood is light, soft, and of a reddish colour, like redwood or *Taxodium sempervirens*. Of this vegetable monster, 21 feet of the bark, from the lower part of the trunk, have been put in the natural form in San Francisco for exhibition; it there forms a spacious carpeted room, and contains a piano, with seats for 40 persons. On one occasion 140 children were admitted without inconvenience. An exact representation of this tree, drawn on the spot, is now in the hands of the lithographers, and will be published in a few days."

Former periods of our national history have been variously described as the Dark, the Crusading, and the Augustan Ages; and if we were asked as tersely to characterize that in which we are now living, we should say it is the Common Sense Age.

We remarked, last week, upon the absurd system, now abolished, of keeping Kew Gardens closed against the people, it being now reasonably concluded, that if natural beauties and intellectual pleasures are placed within the easy reach even of the poorest, there is still so much of good in human nature, that very many would prefer such gratifications before more sensual indulgences. That the conclusion was just, is told by the myriads frequenting Kew, the Parks, the British Museum, and the National Gallery.

Encouraged by this, Common Sense has carried the facilities for mental improvement a step further; and in the Mechanics Institutes, their lectures and libraries, all well attended, we observe another attractive power at work to wean the labouring classes from debasing habits.

Common Sense, we think, now suggests to go another step onward. Mechanics Institutes provide rational amusement and wholesome instruction for the artisans and the residents in towns, but we now require *Village Institutes*.

A great movement in that direction is organising, under Lord Shaftesbury, for the better supply of rural districts with cheap and good literature; and Lord Ashburton's proposal to have the Diocesan Schoolmasters better instructed in "common things" will be a powerful auxiliary. His lordship offers prizes to the Schoolmasters now training in the Winchester Diocesan School; the prizes to be awarded to those most fully conversant with the things of every-day life. The importance of having the Village Schoolmaster a centre of "science with practice" in all that relates to our bodies, our clothing, our food, our dwellings, and our gardens, is a suggestion laden with most beneficial results.

We had written thus far when we received the following from Mr. Fish. It is highly valuable, as offering the suggestions of a reflecting mind in one well conversant with the wants and habits of those with whom Village Institutes and Village Schoolmasters will have to be in intimate connection:—

"One of our old winters has returned." Many "a merry Christmas, and a happy new year," has been expressed to old friends in the sounds of the living

voice that would have been unheard but for the iron-cased roads which old Jack Frost had kindly provided for all pedestrian tourists. Writing this on the second day of 1854, after a fortnight of weather below the average in temperature, the days of my *teenhood* seemed to come again at seeing many a sturdy youth and rosy-faced damsel, with buoyant steps, hastening on to a father's home, or a grandfather's fireside; and if a dark shade passed over the happy recollections conjured up by such a bright scene, it was my knowledge of the well-known fact, that in the home of many an honest and industrious peasant, the high price of provisions, the cost of fuel, the comparative inadequate remuneration for labour, the uncertainty of obtaining constant work in such circumstances, combined to render the larder less well filled, and the genial fire less crackling and bright than usual.

"Blessings, many, rest on those, who, feeling their responsibility as stewards of the bounties of Providence, have, by distributing clothing, fuel, and food, insured the practicability of their humbler neighbours rejoicing at this season along with them! May more blessings come to those, who, whatever the extent of their charities, never make charity an opiate for concealing from themselves the demand of justice that a fair day's work should receive a fair day's wages; and who, less or more, are imitating the conduct of a Nobleman, who, according to one of our best correspondents, has raised every man's wages 4s. per week; thus guaranteeing the possession of the necessaries, and some of the comforts, of existence, without breaking in upon that self-respect and high-minded independence of feeling so intimately bound up with the honour and power of a people, that they never can be too much encouraged among our working comrades; but which an indiscriminate charity, approaching to almsgiving, never fails to uproot and destroy.

"Let us look around us still further. What is the aspect of our peasantry, as respects knowledge and morals? We hear much talk about "the schoolmaster being abroad;" and how nicely it swells a period, and turns a sentence, to introduce something about the "march of intellect,"—the progress of thought—the force of public opinion—the wonderful doings, as respects advancement and purity in this nineteenth century of ours! No doubt, contrasted with the past, every philanthropist has reason to take heart and rejoice; but, if we compare general attainments with advantages and privileges, we have reason to hang our heads in very

shame. How general are the scenes in these festive times, in many villages, where the cares of home and kindred are forgotten, and a jollity, so wild, as to touch upon the insane, reigns supreme! Those scenes are in the drink-shops. Tobacco, beer, and spirits have so drowned thought and so muddled the mind, that it choruses, to the echo, sentiments so sensual, and songs so immoral, as once would have mantled their cheeks with indignation. Are such the scenes we expect will promote purity of thought and integrity of action?

"Sufficiently *near to*, if not *in*, most of our villages, schools have been established in which reading and writing, &c., have been taught; but it is often *now*, and too generally, until lately, these were taught as a mere act of routine. Too little attention has been paid to imbue the mind of our youths with the importance of these elements of instruction, not so much on account of what they were worth in themselves, but as valuable keys for unlocking whole storehouses of wonders and sources of elevated enjoyment, even should the range of our enquiry extend no farther than the world on which we dwell. Unfortunately, we are so naturally averse to the pure, that, as a too general fact, it is found that the mind, whose reading had been directed little farther than a catechism, or a work on theology, will be too apt to neglect reading altogether. This will be none the less likely to be the case if the few books within reach should in any way be associated with the hard knocks and canings of the village pedagogue. I would humbly submit this last remark to the strenuous advocates for retaining the "Book of books" as a class book in our schools. Even *now*, some of its most beautiful passages are never read by me without a vivid recollection of the thumps I received when trying to read them when a boy. The Bible and the cane we would divorce for ever from coming in contact in our schools. Let it be reserved for those of their classes advanced beyond the infliction of the rod.

"Be this as it may, the art of reading, when acquired, will be lost if not practised. Men have worked with me who could not read nor write, and yet had learned both when young. Others, who practised what they had learned regretted that they could get nothing to read. Just ask yourselves if that is not the condition of many a village with which you are acquainted? What are the men to do in such circumstances?

"I say nothing now of the unfitness of education females of the same classes receive for throwing all the charms of utility, and the more than witchery of a well-balanced enlightened mind as magnetic attractions around humble homes. To our disgrace it must be owned, that girls, as to education, have ever been less cared for than boys, and hence their comparative weakness as an improving influence on the rougher part of mankind.

"Well, what are these men to do? Many of them, you see, cannot read, but they *think*. They cannot help that; every moment thought is thrilling through their brain. What a fact! How suggestive of responsibility! Will that thought be always concealed? No!

Man is inherently social. We all relish meeting with our fellow-men, and exchanging thoughts by embodying them in words. The same of the man who reads, but who can get little to read. He pants for social intercourse. Where shall he find it? In the ale-house. This ability to read the paper makes him a sage and a philosopher there. The man who cannot read has ears; becomes almost as learned as his reading brother, and learns to talk of murders and sensualism as glibly, until too often the hearts of both become as hardened as those of the perpetrators of the villainies on which they delight to linger.

"Shall I go to the home of such men, and, beholding the broken furniture, the tattered bedclothes, the general misery, denounce them as all that is vile? Nay; a word of love would be more powerful than that! Rather let us ask, 'Have I nothing to do with this man's vice and misery? Have I, knowing that character is so far moulded by circumstances—have I, knowing the strong impulsiveness of human feeling—have I, knowing that mind must be incessantly active—have I—knowing all this, and feeling all this—done what in *me* lay, that my erring brother should have means and opportunities for his faculties being employed upon the pure and the elevating, instead of revelling among the gross and the degrading?'

"Responsibility in these matters is now becoming more felt, and I am happy to say that gardeners and their employers are not behind in the movement. Reading-rooms, at times combined with a coffee-room, good libraries, and occasional lectures on generally interesting subjects, in homely language, would constitute, in time, great opponents of the beer-shops. From the correspondent I have already alluded to, a gardener to a nobleman, I lately received the following account of the forming of a village library:—'We have just established a reading-room and library in the village of S—, which is only about half-a-mile from the garden. The room will be lighted and warmed from six o'clock to ten in the evening, and supplied with the *Times*, *Illustrated London News*, *Cottage Gardener*, *Gardener's Chronicle*, *Sussex Express*, *Mark Lane Express*, *Builder*, *Household Words*, and many other periodicals. Our library is not extensive at present, but we are in hopes it will improve as we go on. Members are to pay 1s. entrance, and 6d. per month subscription. We have had several meetings respecting it, and have now got about forty members. Mr. S., the tutor at —, has been its chief promoter. The clergyman has also taken an active part, and his lordship has become patron, so, altogether, I am in hopes we shall be able to do some good, although, I am sorry to say, the people in this neighbourhood are not very fond of such things. I am in hopes it will keep many young men from going to a public-house at night, as the room will be pleasant and warm, with plenty to read for amusement and instruction.'

"Who does not join in the hope of our friend? Who does not feel grateful for this double example of kindness in the nobleman referred to? Had I to make a

similar effort, I would do away with the entrance-money, reduce the fees to 2s. or 3s. a-year, and thus encourage the peasantry to be members; for though contending against making working men recipients of charity, in any shape, let us advocate knowledge being placed within their reach on the easiest possible terms. Instances are known to me in which such institutions never got beyond *Struggle Point*, until the terms were made so low as to invite the masses. Numbers here are everything as respects energy and usefulness. A man that can pay sixpence is nothing to six men who pay one penny each.

"Then, as hinted above, if our friend was to give a short lecture on gardening, and the worthy tutor, and the good clergyman, were to do the same as respects natural history, mechanical philosophy, social economics, &c., a variety and interest would be added that would be both pleasing and improving.

"Knowing the exciting temptations of the liquor-shop, we have but slender hope of seeing great improvements in our large villages until such institutions are introduced, combined with good-sized gardens, or an allotment for every cottager."

We shall be much obliged by our readers informing us the lowest degrees of cold they have observed, recorded by their self-registering thermometers. One correspondent, at Bury, in Lancashire, says:—

"My registering thermometer, last night (Dec. 27th), indicated 7°, viz.:—25° below freezing point, and at 8 o'clock stood at 13°. I am anxious to hear if the frost has been as severe elsewhere.—W. X. W."

On the same night, at Southampton, the thermometer was at 24°, but on the 29th it fell as low as 18°. At Chiswick, on the 16th of December, it was at 7°, and on the 28th at 8°. At Croydon, in Surrey, on the 29th, it was 15°.

These temperatures, however, are far above that of the night of January the 3rd, when, near Nottingham, the thermometer sank to 4° below zero, or 36° below the freezing point of water. We shall be glad to know what was the lowest temperature of that night in different parts of England.

Mr. E. J. Lowe, of the Observatory, Highfield House, near Nottingham, says,

"The following are the temperatures of the coldest days here since 1809:—

1810	..	Feb. 21	..	12°	above zero.
1814	..	Jan. 9	..	4°	"
		" 13	..	3°	"
		" 14	..	5°	"
1815	..	" 23	..	11°	"
1816	..	Feb. 9	..	2°	"
1820	..	Jan. 1	..	6.5°	"
1823	..	" 19	..	6.5°	"
1826	..	" 15	..	11°	"
1830	..	" 19	..	10°	"
1838	..	" 20	..	9°	"
1841	..	" —	..	4°	"
1845	..	March 14	..	13°	"
1854	..	Jan. 3	..	4°	below zero.

° On the 14th of March, 1845, the temperature, on the grass, fell to 1° below zero; to-day (Jan. 3) that tempera-

ture was 6° below zero (as indicated by several corrected thermometers), and at 4 feet above the ground, upon a flat board, 8° below zero."

CULTURE OF COLEWORTS—SUGGESTIVE.

About thirty years since the culture of these most useful vegetables was principally confined to the market-gardens about the metropolis; our ordinary country gardeners knew and cared little about them. In later years, however, their culture has been much on the increase; our markets have been so abundantly supplied with them at all periods, that their importance has become familiar to all classes, and almost every private garden of importance possesses, at least, a winter supply. Indeed, so much have they increased in esteem, that they have gone far towards supplanting the larger Cabbages. As some confused notions are abroad concerning them, it will be well to state here in what their peculiarity consists. The fact is, that a new race of Cabbages may be said to have sprung up, of which, probably, the *Dwarf Early York* is the parent, at least, on one side; but most of them are far superior to that once useful kind, in being more succulent and fuller in the head, for the *Old York* had a sort of twisted character, which detracted sadly from its value. It is well known that our market-gardeners select for seed from those with thick and succulent midribs in the leaves, as making them of superior quality, and as bunching better for market; and in this respect such kinds as *Barnes's Early Dwarf*, *Atkins's Matchless*, &c., when from a *true stock*, are far superior to the *Old York*.

Now, it so happens that most of these improved dwarf and early-hearting kinds produce a very superior amount of sprouts to the old *Early Yorks*, and although the market-gardeners care not a fig for sprouts, private gardeners frequently find them of great service. Market-gardeners have to pursue a more rapid rotation, based, in the main, on the peculiar demands of the market,—they must produce any given crop when it fetches the highest price; the private gardener, on the contrary, has to consider the peculiar needs of a given family; and it not unfrequently happens that his crops are of the greatest importance in this respect, when they would be of least value in the market. In this way, then, stands the relative position of the parties; and I consider it very necessary to all little gardeners, whenever old blue aprons undertake to explain sound maxims of culture, to clear away those mists which have too long formed a kind of halo around common sense matters, and either dimmed the eye of the would-be learner, or so refracted the rays of light, as to make plain matters appear distorted or unsatisfactory.

I well remember that when the "*Atkins's Matchless*" Cabbage first came up, and when, of course, it might be had in much purity, planting about ten poles of ground with it about the beginning of July. The land had been deeply trenched for the preceding crop, and much of the subsoil brought to the surface,—this subsoil a reddish sand, called, in Cheshire, "*bootel*" sand, from a slight tendency it has to the clayey principle, for when squeezed in the hand it is slightly adhesive. The ground was well-manured with old hotbed linings, which was first dug in a spade deep, and then forked over,—a favourite practice with me when I can spare so much labour, for I find that it makes the soil, for about ten inches in depth, a well-mixed compost, and the dung being old hotbed linings chopped into mince-meat, a most complete mixture takes place, and not a fibre but has food close to it—the soil, also, thus preserving moisture in a summer's drought. These Coleworts were planted at a distance averaging one foot apart, and when they came in use, which was through September and October, their heads, or shoulders, thirty

met each other, and being used up betimes from the circumstance of their being in such a congenial compost, they sprouted forthwith, and by the middle of November the whole surface of the plot was one uniform mass of young sprouts, and never before or since have I seen such a marvellous produce. As I always sow a successional crop about the last week of June, which period would be too early for our more southern neighbours, we had no occasion to use the sprouts until the succeeding February and March, when they produced thousands of what might be termed small Coleworts, just what our fancy cooks like, and forming a valuable connecting link between the true winter Coleworts and the early spring Cabbages of the dwarf and early-hearing kinds. But, be it remembered, this mode, with the best of soil, can by no means carry out the designs of the cultivator, unless the kind be genuine; and of this, together with the disappointments incident to the cultivator through the unguineness of spurious kinds, albeit well prepared and well named, more in a succeeding notice.

And now I have attained, I hope, a point, as to vegetable economics, which was, indeed, the aim I took in taking, "the Colewort, and its culture," for my theme, viz., to shew, that even in the culture of so simple a thing as Dwarf Cabbages, a progressive improvement in culture (as to copious supplies to meet the demands of families from their kitchen-garden) has really taken place, as compared with the kitchen-gardens of some twenty years since; I have, therefore, to suggest, that those gardeners who still adhere to the old system of growing heavy crops of summer Cabbages of large size (famous, to be sure, on exhibition-tables, as astonishing those who are simply gratified with a sudden display), just give the subject a second consideration, and see whether the conveniences and comforts of a private family in the country be not rather enhanced by a capital vegetable garden, which keeps, as they say, "the pot a-going," than by those diversions which are created by extraordinary specimens occasionally, and which, whatever merit they may possess, too often serve to decoy the attention from matters less specious, but of more general utility.

I much fear that our great exhibitors, who live near great towns, where a big dust must be kicked-up occasionally, to evince progress, will blame me for thus, as they may say, decrying the exhibition-table. I must beg, however, to assure them, that no one can admire a big cabbage more than myself, although a *Drumhead*; and that when I feel a strong appetite, I should, certainly, prefer a big one to a small Colewort for my dinner; but such narrow views must not be allowed to settle a whole case, and that these *ex parte* ways of settling an affair, although sometimes very popular, are not entirely worthy of the age we live in. The great fact is in the exhibition of vegetable specimens which astonish by their size, that they ought simply to be considered as samples of what *may be done*, rather than what *ought to be done* on every occasion. If any prefer the exhibition-table to a good round of domestic conveniences, I have no right to blame them; but still it is proper such persons should know that not unfrequently such aims are rather antagonistic to that constant and useful supply in a long succession which is so agreeable to our cooks. When, however, the case becomes agricultural rather than horticultural, it is purely what has been termed a "breeches-pocket argument." Generally speaking, he who can produce, in one crop, the greatest amount of produce from a given space of ground is the greatest hero. Thus it is that gardeners are not always more successful than Mr. Meehi: their balance sheets will not please everybody.

It is well for those of our friends whom we can manage to impress with the due amount of importance,

the subject deserves, to observe, that from the second week in June to the middle of July is the period when a proper succession of Coleworts should be sown; and that they *must be* dwarf, early-hearing, round-hearted kinds; as for names, we are in danger of being swamped with them. Our market-gardeners, who, many of them, save their own kinds, hold the seed-shop names in supreme contempt. The fact is, that be a seedsman what he may, *he cannot* undertake to produce kinds in perfect purity; his business is too complicated to admit of it.

Plenty of manure is indispensable to their culture; for Blue Cabbages, which are the result of poor land, drought, or club, are, by no means, sought after by good table men.

One point more. I hold it good practice, with the private gardener, to take up well-hearted Coleworts in the end of November, and "heel" them right close together; and as soon as a stiff frost sets in, and the ground is well seated, to cover them with loose litter, keeping them frozen with all his might; and when they *must thaw*, to take care that their final thawing and inurement to light runs over about three days, avoiding sudden sunshine. All this requires care, of course.

R. ERRINGTON.

PRESERVING AND SERVING ICE.

ICE crowned the last days of the old year so completely that all the ice-houses and ice-cellars in the country are now, or ought to be, quite full of it; *ice-bergs*, or ice-heaps, ought also to be finished, if not thatched, before this sees the light. In our "Dictionary" there are two ways named for doing the ice, one of which, with plans, is by the late Mr. Cobbett, and the other by your humble servant. Any one who follows the last plan need not fear about the safety of his ice-heap until ice comes again; or, at least, till ice-time comes round, whether we shall have ice then, or not; and any one who follows Mr. Cobbett's plan will assuredly find his ice run short when he most needs it. Some one played off a hoax upon Cobbett about keeping ice, and the ice world was so much divided upon the subject, for many years after his plans were given, that this hoax got into a ready circulation among all the books and newspapers on gardening. No one ever wrote more clearly than did Cobbett, and that was the main reason why so many people in the country read his works, who never believed one-half of what he said on politics, and in his wranglings with those from whom he differed in other things; hence the great demand for his "Cottage Economy," in the sixteenth edition of which the hoax about keeping ice first appeared; but he said the plan was not his own, he only believed what some one else told him of it; and he said, that if the plan should fail, the house he proposed would be a model for a pig-stye for all generations. Those who have not the "Dictionary," or access to that edition of the "Cottage Economy," will understand the plan from this description of it:—A strong pole is fixed in the ground like the handle of an umbrella, fifteen feet long; the umbrella roof is of straw, and four feet thick; the wall all round, and up to this roof, is also of straw, and of equal depth, and the circle within is ten feet across. The usual drainage is very good, and the ice is to be packed all round the centre post up to the roof, and if any of our readers can keep ice with that contrivance till St. Swithin's day, I pledge my word that I shall go down to him to ice the things for his next party dinner, if he only pays me for travelling expenses. The great error in this plan is the centre post, thirty inches round, without it the ice would keep double the time, but it is only waste of time and money to make so small a heap as this; although it is ten feet across, the real diameter of

the ice is only five feet, and that includes the post in the middle, where the ice will give way first. In a very short time there will be a wasting cavity all round the post in communication with the air at the open drainage, and the air at the drainage being warmer than the air in contact with the ice along the cavity, a column of it will rise round the post, and not finding a vent at the top, it ebulls and falls down by the side of the ice, and thus a constant circulation goes on, wasting the ice more and more till all is gone. A walking-stick, even a straw, or a dry leaf, in the midst of ice, soon makes a cavity all round it.

It would have been unpardonable in us to have left out Cobbett's plan from the "Dictionary," because it had a world-wide celebrity, but it would be worse, if we did not show the utter impossibility of securing a supply of ice by it in our country. Cobbett was as well aware as any of us that damp is the great enemy to ice, and he is quite right in advising to have it in a dry place, and away from the drip of trees; farther than that, he knew nothing practically on the subject at all, as he himself acknowledged, but his admission is not known to one in ten who heard his scheme recommended.

Others have recommended salt and salted water to be poured on the ice, from time to time, as the ice was being packed. That idea must have originated from not understanding the reason why salt is so largely used with ice by the confectioners for producing an intense degree of cold for freezing their mixtures, but that very cold is obtained at the expense of the ice, which melts much faster with salt than without it. I have known one or two gardeners who used salt in packing their ice, and kept a good supply, notwithstanding; but that cannot affect the question; they might have had more ice left at the end of the season if they had not used the salt, and, which is the same thing, the quantity of ice put together might be much less when salt was not used.

The next question is watering ice at the time of packing it, in order to make the whole into one solid heap by the freezing of the water between the particles of ice. Whether this watering does more harm than good, or any good at all, depends on circumstances. If the ice is thin, so as to be easily pounded very small, and that it is so pounded on a keen frosty day, there is no doubt but the watering will cement the ice more firmly, so to speak, therefore, the less air is left in it, and the longer it will last in consequence. But if the ice is very thick, as a good deal of it has been this winter, the men will not pound it small enough for the watering, pay them as you will, or make them half drunk to excite them to the work. The thing is impossible, for there is not another kind of labourer's work half so distressing to the limbs; coming in their way but once a year, they never get so used to it as to be able to stand long at it without slacking; all that I know quite well from a long experience, and I dwell on it, because I know, equally well, that there are many masters who blame their gardeners, or any men in charge of labourers, if they do not get more work out of the labourers on certain occasions when a pushing job like this comes to hand. It is quite true, that a gardener, who understands the right way to manage a set of men properly, can very easily get an extra job done quicker, now and then, than the usual run; but that does not apply to the icing days. Therefore, seeing that strong, thick ice cannot be got broken so small as to be safe to use water from a rose pot with it, the best plan is not to use water in such cases. Then, again, if the ice is not finished while it yet freezes, as often happens, the water will not freeze much by the mere coldness of the ice; and, there being cavities innumerable in a heap of lumpy ice, the water playing into them on a soft day, and perhaps the finishing day, will do a great deal of harm.

The next question for consideration is snow and ice put together. Now, I must confess that I have very little practice to bear on this question. I have occasionally ordered the sides of an ice-heap to be plastered, as it were, with snow, and I never found any ill effects from it, neither can I say it did much, or any, good; but, judging from what I have seen of snow-heaps that were made for the purpose of icing, when ice could not be had, and knowing that salt and snow melting together will cause a more intense cold than ice and salt, and also knowing that the fiercest sun, in our climate, has not the slightest perceptible influence on the surface of a deep snow wreath, if the air is allowed to play over it, I am quite satisfied in my own mind that snow is just as good and useful as ice, and is as easily, if not easier, kept than ice by itself, and that packing ice-heaps with snow, as the work goes on, is the best practice; and I should think that the drier the snow was at the time the better it would answer the purpose. If we put two parts ice and one of snow together, in filling an ice-house, or in making up an ice-heap, I should say that would be about the right proportion; but let me be understood as having no actual experience on that point.

I think the question between egg-shaped ice-houses sunk in the earth, and ice-heaps put together in the open air in the form of a sugar-loaf, is now decided, by universal consent, in favour of the latter; but whether the question of confining the air in an ice-house, on the old stalling principle, be settled, or not, I cannot say. I am satisfied myself that such confining of air is decidedly a wrong practice.

I have thus touched, briefly, on all the mooted points that have been discussed on this subject, as far as I am aware of, except that of keeping very thick ice, such as that from America; of that I have no experience, nor do I think it of public use if I had. All the ice for this season, among ourselves, will be gathered and stored before this appears, and that is what I have wished before I said anything more about it, because I did not want to open the question again, but before the end of the year I should much like to hear of the different modes of packing ice which have been put in practice this season; the quantities that were put together in different places; the kind and depth of covering; and the result of the whole, as to how the ice is kept, as, notwithstanding our present experience and success, who can say but a better way still may yet be found out?

And, now, for the long-sought-for information about making ice-plates and dishes, to set iced things upon at breakfast, or on the dinner-table. I have not to go to Mr. Gunter for the receipts, for I have had a pitched battle against his best man since I promised to tell of my own ways. We actually excelled Mr. Gunter's best *frigorifics* when Prince Albert dined at Shrubland Park; but I now forget the name of his manager there, who acknowledged the superiority of our Suffolk manufacture. I have dined with him, however, there, and with others, who saw how things were got up in different parts of the country, on such occasions, and making allowance for good breeding, and "present company," the palm was spread in favour of the "present occasion," &c., &c. If you saw "how things were got up" for the last Christmas dinner, when no ices were wanted, believe me, it would not have taken away your appetite as it did—I mean, by partaking of it so freely.

How to make hoar-frost by the side of the kitchen fire was a problem with us boys when I was at school, and the whole art and mystery of making iced things, ice-plates and all, is on the same principle; but we must not confine the subject so much; for I venture to say that there was not the value of a pin in the Crystal Palace which could not, in miniature, at least, be represented in ice as clear as crystal, beginning with the

crystal fountain itself, and so all round to the English dolls. To make hoar-frost by the side of the fire, you have only to take a wooden pail, or bucket, with iron hoops on, and half fill it with snow, and mix one-third common salt with the snow, and set the bucket so near the fire that the heat will melt the snow. As the snow melts it dissolves the salt; and the melting will produce such intense cold as will make actual hoar-frost on the iron hoops, and sooner, if they are wetted a little, on the side farthest from the fire. If the wood of the bucket is damp, and an equal quantity of snow and salt is melting, the hoar-frost will soon appear on the outside of the bucket, but not so soon as on the iron hoops. I have seen this done scores of times; and the wildest and most mischievous *prank* a boy can be guilty of is to get another boy to put his tongue on the frosted iron hoop, pretending that the hoop is hot all the while—in two or three seconds the tongue will stick to the hoop, so as to tear off the skin before it can be released—so let no one try this experiment until he learns to take off the tongue as quickly as the twinkling of the eye.

Now, a bucket more than half-filled with ice pounded very small, and a good quantity of common salt mixed with it, will give nearly the same degree of cold any day in the year; and so things are iced. Every iced thing one can buy in London is done by ice and salt melting in a wooden vessel, or ought to be in a wooden one; but, of course, any other vessels might answer nearly as well. The iced things you buy at public stalls near London, and other large places, might have been made at Inverness, and sent up in wooden casks, packed like Dutch and Irish butter, if they had free communication by rail beyond Aberdeen so far; then they scoop it out of these casks with strong wooden spoons, put it on china plates—then, and not till then, is it ready for your order. Pewter vessels are the best to put the creams in for icing, and they are to be bought in London of all sorts and sizes as easily as beer pots, but I do not know where in London.

To make a bowl, a tea-cup, or a plate, of ice, all that you have to do is to get the mould (of pewter), fill it with the clearest water, and put it in the ice-bucket, covering it all over with a little salt, besides the salt already mixed with the ice in the bucket; let this be done two hours before the plate or other vessel is wanted at table, and place the bucket in a cool room; the larder is as good as any place in summer; in the winter time any place will do away from the fire; just when they are ready to go in to breakfast, have so many pats of butter, made that morning, standing on ice, and get a nice common breakfast-plate on the ice, with the butter, but the butter must not be on the plate that goes to table. Now, get out your pewter-plate mould, and before you open it, plunge it in a bucket of warm-water, such as you could bear your hand in, and leave it in half a minute, but you must learn the exact time by experience, as one mould requires more time than another that might seem of the same size and substance; the reason for dipping the mould into the warm-water is to free the ice-plate from the inside of it; now open the lid of the mould, and slip out the ice-plate on a clean, dry cloth or towel, wipe it all round, to get off the damp caused by the hot-water, and put it on the cold china plate, and put the cold butter on it, and off you go as fast as anything straight to the breakfast-table, and who knows how the crystal plate and cold, firm butter was got; but there it is, sure enough.

Imitations of Strawberries, and other fruit, also of all kinds of fishes and birds, fancy things, and what-not, may be done in ice after the same manner, for the dinner or breakfast-table. For *pic-nic* parties, what is easier than to carry along with you as much of iced-cream as will cool the whole party, in little wooden

casks or jars, rolled in woollen cloth or Welsh flannel. Mr. Gunter would send any quantity of ice-cream to Aberdeen, and it would be as firm and cold as when it left his still-rooms in London, till the last particle of it was consumed.

There is a good deal of practice and expertness required to manage all this, and the first attempts will be like the first lessons in music, or drawing, or dancing, or anything else; and for a whole life-time some persons will succeed much better than others. In getting up fifty varieties of things, or moulds, out of the ice-buckets, one person ought to manage the plunging hot bath, and slide out the ices as fast as possible, on something cool and dry; and a second to take them up equally fast, and arrange them on cool plates or dishes; and a third carry them off to the dining-room with all speed. But be sure of one thing—see that any deformed article is not the perquisite of the operators, else there may be more of them than will cool their ardour in the work.

Ice-buckets ought to have a few drainage holes at the bottom to let off the water as the ice melts, and wooden hoops are better than iron ones, as the latter rust, and take the cold faster to their sides. As to the real quantity of salt to be used, I cannot just say, by weight or measure; the very commonest will do, and if you were to put weight for weight of ice it would not spoil it, but far less will do, and you will need much more of the salt in summer. D. BEATON.

SNOW AS A PROTECTOR.

“My cold pits have got covered with snow; shall I sweep it off, so that the plants beneath may have a little sunlight, when there is any in these frosty days; or should I allow it to remain until a change in the weather removes it? I don't mind covering and uncovering, if I shall advantage my plants by my labour.”

This is the purport of many enquiries from friends who cannot see how our general principles are to be applied to particular cases. If only part of what has been said of protecting materials be correct, then snow, when loose, and sufficiently thick to prevent frost penetrating, is one of the very best protectors we could use. Its colour places it low in the scale either as an absorbent, or a radiator of heat. Even where there is a little sun, about the shortest day, if the frost is at all keen, the sun will affect the snow merely on the surface, and what is softened there will be congealed again by the frost of night, but still leaving a quantity of lighter matter beneath it. As long as this light, flossy matter remains between the glass and this surface that is softened and hardened by turns, there will be no danger of frost of a few degrees penetrating by the glass that would injure half-hardy plants usually kept in such places. Care should, however, be taken that the frost does not enter through the walls, or by the ends of the sashes where they rest on the wall plates. When, however, the snow is alternately melted and frozen, so as to resemble a cake of ice on the glass, it would then be necessary to throw some litter over all to prevent the greater radiation of heat from within, as the very compression of the snow squeezed out, as it were, all the confined air, the possession of which, independent of its colour, made it a bad radiator, and a good non-conductor of heat.

Now, if in such a pit the heat within was not high enough to melt the snow contiguous to the glass, that heat would not be sufficient to lengthen the tissues of the plant, nor yet to cause fungous broods in the shape of damps to spread. Hence, for the mere preserving of a plant—the maintaining it, so far as its nature will permit, in a state of healthy rest—it matters but little whether that rest be a period of fourteen hours or four-

teen days. In such a long night as the latter period there must be no extension of growth. As low a temperature within as the plants will stand without injury, is the first essential of safety, when we wish, from motives of economy or necessity, to keep half-hardy plants shut up night and day.

In the case of hardier plants, such as Cauliflower plants under hand-lights, whenever a frost of a week or so is expected, and the days are too dull to give the plants any advantage from uncovering that would compensate for the labour, it is preferable to have the plants and ground slightly frozen before putting this night-cap in the shape of protection over them. The cold pits under my care have not been uncovered, now, for almost a fortnight. Some of the tenderest had straw covers over them previously; others had a little dusting of rough hay shaken over the glass; and some had merely the protection of the glass. The weather, as respects cold, seemed threatening, and more protecting material was got in readiness. A fall of five inches of snow was hailed as a temporary respite from a regular attack on the little hay-rick we had saved from the first mowing of the least prominent parts of the lawn. The sun, on pits facing the south, when it did shine, lessened the thickness of the snow, and on these places, especially where it was likely to disappear altogether, a little hay was shaken on, or litter of any sort; but as to ease our trouble in this respect, it has happened, several times, that when we were thinking of doing this another slight fall of snow has come and thus saved us the trouble.

Plants under frames, on a north border, such as the little bedding *Calceolarias* mentioned the other week, and which have not yet been touched, are all quite comfortable under their snow mantle. The sun, when it did shine, never touched the snow there. I find that these pits, owing to the heat stored up in their bottoms, &c., and with this mantle over them, which, while it lasts, prevents heat and cold easily penetrating, have a very equable temperature, ranging from 34° to 38°. Did I allow them to remain in such a darkened state, with a temperature 10° higher, I should expect to witness, at the end of a fortnight, a quantity of miserable spectres, though, if this weather should last for a month, I feel confident that when uncovered then, the plants will look as nice as a field of Wheat, that for a similar time, and a similar agent, has been shrouded from the light of day. If the snow fell on the field of Wheat after the ground was crusted with frost, the farmer knows that many of the enemies of his favourite crop will be kept inactive, and that when the snow disappears his crop will look much the same as before it came. But if, as sometimes happens, a good fall of snow should take place when there has been no frost to affect the ground, though frosty weather afterwards causes the snow to remain, everyone knows, that when, after a gradual thaw, that snow has gone, the Wheat plant will be found to have grown, at least to have extended in length, and if not exposed afterwards to sudden frosts when in this tender state, the farmer has reason to look upon such a snow fall as his best friend. Now, what in this latter case affects but a little in the way of injury such a hardy plant as the Wheat, even when long covered, would be apt to spread destruction among a pit of half-hardy bedding plants. Suppose, for instance, that in an afternoon the enclosed atmosphere of such a pit should be 45°, the external heat 38° or 40°, but that owing to the air being more rarified and cold between us and the clouds, the moisture that otherwise would have reached us as rain descended in the shape of a heavy fall of snow, and that on the score of economy we wished to secure that snow as a protecting agent, so long as the frost which it brought with it continued, then the true points of safety would be to reduce the temperature within, by tilting the

sashes a little behind, so as to take away every inducement to make the plants lengthen and grow while thus excluded from light.

The question of uncovering cold pits, by sweeping off the snow that envelopes them, so as to give them light, becomes thus a matter of expediency, economy, time of the year, and object aimed at. For instance, when in such places we wish to grow on plants as fast as we can, and the labour can be commanded, which, after all, is not much where there are only a few glass sashes altogether, then no safe opportunity of giving sunlight should be missed. Was it my object to *keep* merely as great a number of small plants in as small a state as possible, so as to economise time, room, and labour—then, during the months of November, December, and the first part of January, I should be sorry to sweep off a good covering of snow under such supposed circumstances of continued frost; because, in the first place, I should quite despair of getting any frigidomo, in the way of a protector, equal to the snow, whatever price I paid for it; and, secondly, because, in addition to knowing that the plants were kept in the stationary circumstances I wished them to be, I know that what sunlight they could get under such circumstances would not, in the way of advantage, counterbalance the labour of uncovering and covering, and the getting of the protecting material in the stead of the snow. But suppose, now, that I wanted these tiny things to take a bit of a race in growth, so as to attain some size by April and May; and suppose, again, that we had a snow fall in March, and sunny days afterwards; I should not hesitate in clearing away the snow to admit sunlight then, so as to induce and consolidate growth. Circumstances, then, must regulate our procedure.

In all we have said above of half-hardy plants being safe under glass with a covering of snow, it must be understood that we mean the snow to be thick—from six to twelve inches—and the frost not very severe. When the snow was only one or two inches thick, and the frost was 10° to 20° below the freezing point, the sun, obeying the laws of radiation, would soon let the frost penetrate, and plenty of other covering must be held in requisition, in addition to or without the snow.

Two words more. If the frost should penetrate, never uncover until some time after a thaw has come; and, again, if long shut up, give the plants subdued, not full, light at first.

R. FISH.

THE WOODS AND FORESTS.

(Continued from page 231.)

THINNING A NEGLECTED PLANTATION.—This is not an easy task to do effectually without injuring the trees that are left. It requires considerable judgment and experience, or the trees will be so injured by a too sudden exposure to the cold air rushing through them as to be several years in recovering the effects of it. I have seen young slender Oaks completely killed by a too severe thinning. The best way, in such a case, to proceed, in my opinion (and I am borne out by practice), is this—

Supposing a plantation, no matter to what extent, has never been pruned or thinned till the trees have grown so high and so thick that all the lower branches are dead, and the lowest of these have dropped to the ground; the very tops of the trees only have branches, and these touch each other; the poles of such a wood will be tall and slender, and, therefore, when one is fixed upon to stand, and all the others near it are cut down, this tree to be left for a noble timber tree will look something like a birch-broom stuck into the ground, the broom end upwards; this appearance the best woodsman in the world cannot remove; but he can

prevent, in a degree, the serious injury that would accrue, by first going through the wood, and marking, by some means or other (a circle of red paint is a good method), all the handsomest and best trees, at such a distance from each other as would allow them sufficient space to form good heads when they have space to expand their branches. Supposing there are five trees between these standards, as I may term them, then let the marker, with some other kind of mark, place it upon the two trees on each side of the standard. These are to be cut down that season, and these will leave three trees standing as a protection to the standard till it has become partially prepared, as it were, to stand by itself.

This opening-by degrees process will give the standard, also, an opportunity of sending forth a few more branches down the stem. (I refer more particularly to deciduous trees.) This putting forth of new branches must have been observed by any one in the practice of thinning woods, and these branches assist very materially in enabling the tree to acquire more strength to withstand the strong draught that it will be exposed to when the second thinning is done. The standard tree should have two seasons allowed to get used to its partially unsheltered position. In the third season, two of the three trees left should be removed; there will then be one left, and the standard will have to bear a much greater exposure to cold winds, but it will now be enabled to bear them; it will have acquired two years' additional strength, the wood will be more consolidated, and the roots will have had a larger space to gather up strengthening food. Imagine the difference between this preparatory thinning process and that of taking away all the five nurse trees at once. Any common-sensed man must perceive that it is better to thin by degrees.

"Oh but," says one, "it is too much trouble; and do not tell me: the trees that are left are natives of this country, and are hardy enough; they will stand any breezes, and will soon thicken, get stiff and upright, and will then have nice clean boles without any fuss about thinning and pruning." Such is the language too often used by the managers of the woods of this country, but I do trust the proprietors of such neglected wood will open their eyes and see the folly of such let-alone doctrines. Trees, like every other production of the field, are given to man to dress and keep, and no owner of woodland, if he neglects it, is excusable.

To proceed with our thinning process. The one nurse left should remain to fill her office for at least three years more, so that the whole process of thinning a neglected plantation will extend over a period of seven years. The trees for timber will then have become proof, by gradually acquired strength, against all storms and cold winds. If it is desired, the space between and under the trees may either be planted with proper under-wood shrubs, such as Hazels, Hollies, Laurels, Rhododendrons, &c., or the trees that have been felled may be allowed to produce stools of suckers, or the whole ground may be dug over and sown with grass. All these considerations, or practices, depend, of course, upon the will and objects of the owner. If game is desired, the underwood will be cherished; and the best protection for pheasants I ever saw was made by plashing the whole of the underwood so that it formed a perfect unpassable thicket. No poacher could possibly penetrate it, and the owner, now, alas! defunct, soon had the finest preserve of pheasants in the country. This wood so plashed had been a neglected plantation.

THE IRIS.

(Continued from page 263.)

A BED of the Spanish and English bulbous Irises is, when in flower, very effective, and, as they flower during the summer months, they should be made use of more than they are as bedding-out plants.

The species are named *Iris xiphium* (from *xiphos*, sword-like, the leaves being of that shape), and *I. xiphoides*, which means that the latter's leaves are like those of the former. They are distinguished from each other by the petals of the first being as narrow as the flat-shaped stigmas, and the germen or seed-vessels being round; whereas, *xiphoides* has the petals broader, and the germen acutely angular. These are distinctions sufficient to separate the species. Each species has been hybridised, and there are numerous varieties now cultivated chiefly distinguished by the sporting of the colours.

Propagation: By Seed.—Every amateur in Florists' flowers that propagates them by seed ought to be more anxious to improve the variety he saves seed from than merely to increase the number of roots; hence, no seed should be saved but such as has been hybridised with a view either to improve the form, the colour, or the size. Now, in order to succeed with more certainty in attaining these objects, the pollen of the one possessing one of these qualities in the highest perfection should be dusted upon the stigma of another possessing the property of size. From such hybridised flowers the best seeds most likely to bring improved flowers will be obtained. All other blooms that have not been operated upon should be cut off as soon as the flowers fade.

The seed will ripen about the end of September, and should then be gathered just before the seed-vessels burst. Examine the bed daily, and cut off such seed-pods as appear to be quite ripe; lay them as they are gathered upon a large sheet of brown paper placed in a window where the morning sun only will shine upon them; in this position the ripening process will go on, and the pods will open one after another. When all are gathered, and properly dried, then clear the seed from the cases; let them lay another day or two exposed to the sun to harden them, then put them up into brown paper, and place them in a drawer in a dry, cool room. Mice are very fond of the seeds, and will soon eat and destroy the stock, if they can get at them; therefore, the seed should be put in a secure place, where it will be safe from their depredations.

In early spring, prepare a place to sow the seed in, the best will be a gentle hotbed, with a one or two-light box upon it; but if that cannot be conveniently had, it may be sown in square boxes, or flat earthenware pans. The soil proper for them is good loam, sandy peat, and leaf-mould, in equal parts, thoroughly mixed together, but not sifted. If the hotbed is used this compost should be at least eight inches thick. If boxes or pans are used let them be well drained. The surface of the soil should be patted gently down and made quite smooth, then sow the seed rather thinly upon it, and sift some of the compost through a rather fine sieve upon it, taking care that the seed is not buried too deep; the thickness of a crown-piece will be sufficient. Place the light on the frame, giving air night and day, unless it be very frosty. Those in pans may be placed in a greenhouse.

As soon as the seed-leaves appear then increase both the quantity of air and water freely, but at distant intervals. I mean, thoroughly wet the soil once, and then water no more till the soil is dry again. Continue this treatment through the summer, till the leaves begin to turn yellow, then withhold it. As soon as the leaves are quite decayed, then sift the soil through a very fine-

meshed sieve, picking out, as the operation is going on, all the young bulbs, even the very smallest, for the smallest may produce the best flower. When all are carefully picked out, dry them for a few hours, and then put them in a canvass bag, and hang it up in a room without fire till the planting season arrives. In the mean time prepare a bed, three feet wide, and as long as may be needful, to plant them in.

Choose an open part of the garden, and a dry subsoil. If it is not dry it must be made so by drainage. Dig out the soil to the depth of fifteen inches, and then lay in three inches of broken stones or brickbats, and upon them place a covering of thin turf, the grassy side downwards. Fill in the soil again, if of tolerable good quality, mixing it, as the operation goes on, with some dung and leaf-mould, in such quantities as will make the soil rich and light. A little sandy peat would be of service, as also a liberal allowance of river sand, unless the soil be already of a sandy character. With these additions the soil of the bed will be considerably raised; but if the bed is prepared some six weeks or two months before it is wanted, a settling will take place, so as to lower it nearly to the original level, or only just high enough to suit the flowers. In this state let it lay till the month of September, then is the time to plant the seedling bulbs. If there should be any great difference in their size it will be advisable to select the largest size, and plant them by themselves at one end of the bed. Draw drills four inches apart, and three inches deep, across the bed, and plant the larger bulbs (if any) four inches apart in the drill; the smaller size may be planted thicker—two or three inches will be space enough. When all are planted, level down the drills with a rake, and they will require no further care till the spring, after they have made their way to the surface; then, with a small three-pronged fork stir up the soil, to give it a fresh appearance, and to admit freely the warm rains and air of the spring and summer months. In this bed they may remain two years, when some of them will have attained such a size as to warrant the expectation that they will flower. They should then be taken up, dried, and stored, and treated like the old flowering bulbs. T. APPLEBY.

(To be continued.)

PEAS.

SOWING AND PRESERVING.

It is certainly a just and wise provision of nature that the seeds of plants possess a greater degree of hardihood than their parent plants. This is, perhaps, most conspicuous in those of the tenderer exotic natives of the tropical regions, which, though never naturalised with us, yet are enabled to ripen their seeds in our hot-houses, and these seeds are capable of enduring an amount of frost, I might say equal to that of indigenous plants. It is true, a seed is but a bud containing in embryo the future plant; but the same beautiful law of nature has so ordained that the mere bursting of the shell which confines the cotyledon, does not, in every instance, involve the young offspring in destruction, for they are possessed of a greater degree of hardihood at that age than when further advanced. This is especially the case with hardy or half-hardy plants, most of which endure our winters but when in a young state. Now this rule has been taken advantage of by the flower-gardener, who sows his annuals (from the temperate regions) in the open ground the beginning of September, and sees them stand an amount of frost they would not have done had the plants been larger. Subject to the same law is the tenderer kinds of Broccoli and Cauliflower, and many other things, which, having

a duration allotted them, and a duty to perform in that time, are fortified with a power of resisting many inclemencies, which a look at the map of the country they came from would induce a belief they were not able to do.

This example of adaptation to circumstance is of inestimable value in many points of view. Our farmers sow their Wheat in autumn with something like a certainty that nothing short of a Russian winter (without snow) will kill the young plants. True it is that another point bears on this last case, and one that should be mentioned in conjunction with a young plant's hardihood. The seed itself continues to supply nourishment, or assistance, to the young plant long after we might suppose, by its size and habit, that such assistance was needed; and the shrewd, observant husbandman, notices the check the plant receives when it loses that support, which, in local phrase, passes by various denominations; and the plant, left there to its own resources, has to struggle and maintain an existence by its own exertions, aided, of course, by the external circumstances in which it is placed, and the soil in which are its roots.

I have introduced the above observation by way of calling attention to the culture of one of our most useful vegetables, *i. e.* Peas—to obtain an early dish of which has long been regarded as an important point in horti-culture; and in furtherance of this object, the attention of seed-growers and others has been directed to the improving of varieties in cultivation, so as to hasten production as much as possible.

It is generally allowed that the Pea, as well as most cereals, &c., are all annual plants, and that their capability of standing over one winter to ripen their seed in the next season is merely owing to the accidental circumstances of their being sown at such a season as just enables them to attain a size capable of resisting the elements, without incurring a danger of their falling a prey to the severities of the season, which they are sure to do if beyond a certain size. Now, to have the crop of such a size as to secure itself, as well as to produce the earliest possible pods, many things are to be considered—as the position in which the crop is placed in, and the nature of the soil, as well as the latitude of the place; coupled with these, is also a prophetic knowledge of the kind of weather they are likely to encounter, a circumstance as much important to success as any other, and one of which the cottager has as good a chance to foretell as any philosopher, of whatever standing he may be; and as the wisest may be mistaken and at fault, it is advisable, in all cases, to provide against such mishaps as that of a flourishing looking crop of Peas being destroyed in February.

This was much the case last season; the mildness of the autumn and early winter months favouring their growth, they had progressed so far as to be unable to endure the rigours of frost and snow when these tokens of winter visited us; now we know that crops which last year were sown at the same time they had been for many years perished as above, while, in former seasons, they had flourished and done well: the reason was obvious—the mildness which continued so long, favoured their growth to such a degree, that many crops were a full foot high, or more, when hard weather set in, besides being in that delicate state which moisture and mildness imparts. The time at which such crops were sown was somewhere about the middle of November; later crops stood better; those at or about Christmas being the best. Now, this was sufficient to teach all those who did not know before, that, besides the November crop, it was also advisable to put one in at Christmas, the latter being the more certain to succeed.

Independent of taking care to have a successional crop, it is also advisable to look to, and preserve the

first by all available means, for besides the weather, a host of enemies will very likely attack the crop. Mice, in the first instance, will seize and devour the seed just when it is coming through the ground, if not before. Rats are equally destructive, and worse to trap, but they are rarely so numerous. Wood Pigeons are also sad enemies; these are only frightened away by the use of gunpowder; while, perhaps, the worst to combat is the slug, which, in mild seasons, abounds in such numbers as to render the protection of the crop a work of difficulty. Nevertheless, it must be persevered in; and in addition to the use of coal-ashes as a covering, and of lime, soot, &c., as dustings, the rows might also be partly covered with barley chaff, which is one of the best of all coverings, being a preservative against the slug, as well as a protector to the plants themselves. We, therefore, urge on the necessity of this article being more used by gardeners who have the means of obtaining it, for it not only saves Peas, but it will be found useful to other things as well, its sharp points, and angular file-like sides, rendering it a more formidable barrier to the slug than anything else we are acquainted with. It is needless to say that sticks should be supplied as soon as possible; and when severe frost sets in suddenly, after a long period of mild weather, some other covering should be adopted as well. This will suggest itself to the cultivator in sundry ways; and it is not the most costly that is at all times the most useful, for a few boughs of Furze, evergreen Firs, or anything that way, will sometimes serve as well as waterproof covering, &c.

In closing this account, I cannot recommend any one Pea in particular as likely to meet all the wants of the case in hand, for I believe the number of really distinct kinds is much fewer than many people imagine. I have so repeatedly been deceived in a so-called new one being only a "Kent," or "Charlton," that I fear it will not be safe to say which are generally good; but I have found *Warner's Emperor* universally so, and as it is a fair, good kind, of medium height, and not new now, consequently, likely to be genuine, I would recommend it to the inexperienced for the earliest crop. Later crops I will speak of hereafter, as other considerations will determine these; and as the first crop will have been sown some weeks before these pages reach the reader, I would advise those who have not tried this Pea in November, to try it in January, and I question much if the six weeks difference in the time of sowing will make more than half that number of days in the gathering, other things being the same. This, however, with other matters relating to second crops, must be postponed to another time.

J. ROBSON.

MANAGEMENT OF DOWN EWES AS BREEDING STOCK.

(Continued from page 244.)

THERE are two circumstances which concur to make a flock of Down Ewes, as breeding stock, in all probability, more profitable for the future than they have been hitherto; first, the great and increasing consumption of mutton and lambs; and secondly, the almost entire supply of wether mutton being obtained by early maturity, and derived from sheep killed at two years old or under. Coupling these two, with other favourable circumstances, it must be considered as highly encouraging to flock-masters to proceed with energy and judgment in increasing, as much as possible, the extent of their stocks of breeding Ewes.

Early maturity is certainly become a new feature in

fattening of sheep; and, as it is likely to be very much more extended, there is no doubt but it will induce breeders of Down Sheep to use more judgment than has been hitherto shewn in the selection of their stock. This brings us to one of the most important points in the whole range of sheep management; and one upon which the success and profit of a flock mainly depends. For it must be admitted, that those kind of sheep which are most in demand by the purchasers, and which will consume the green crops of the farm with the greatest amount of profit, possess those qualities which should direct our judgment in selection.

Under the head of "Downs," I must name three varieties as demanding our attention, the origin of all, being, without doubt, the South or Sussex Downs; the other two being founded upon crosses with other breeds, and are called the Hampshire Downs and Shropshire Downs. The two latter are at the present day engrossing the attention of breeding and flock-masters to a much greater extent than formerly. It is, however, well known, that all Down varieties of Sheep have been greatly improved for useful and profitable purposes by the advocates and admirers of each particular sort. It may be considered a somewhat difficult task to advise parties to select as breeding stock, for general purposes, any sort in particular, as the soil, situation, and climate must be taken into account. My intention is, however, to offer a few ideas upon the subject, and which are gleaned chiefly from my own experience and observation. For farms situated upon the high and exposed chalk hills of the southern counties of Hampshire, Wiltshire, Dorsetshire, and Berkshire, the improved variety of Hampshire Down proves to be well adapted. There is no question but that they are more hardy than the pure Sussex Down; which fact, together with the advantage of additional size, and early maturity, has influenced the minds of breeders in selecting this variety; and I do not hesitate to say, that the Hampshire breed are quietly making way, and driving the Sussex Downs from many of the above-named districts.

In the south-western counties of Dorsetshire, Somersetshire, and Wiltshire, upon the best soils, where breeding flocks are kept, the Sussex Downs still predominate, although they are greatly improved in size, and in many other respects, since their first introduction, which took place after the Horned Sheep of these districts were given up. Many of the finest flocks of breeding Ewes of these counties still retain the advantages which they derived from a cross with the Horned Dorset; and, although they are, in appearance and general character, South Downs, yet this dash of the breed, together with the influence of soil and climate, gives them the propensity for early breeding, and for the purposes of producing early Down Lambs, renders them much in request by graziers in arable districts.

The Hampshire variety of sheep differ widely in this respect, and their lambing season is from five to six weeks later; nor is this singular, when it is considered that the derivation of the breed was by crossing with the native breed, and that the soil is cold and backward upon which

they are usually kept. The Sussex Downs have still numerous advocates, and although they are found in considerable numbers in many counties, yet they are chiefly found upon their native hills in the county of Sussex in all their purity of breed and distinctness of character. I am somewhat inclined to think, that in this district climate alone favours the perpetuation of the breed, for the soil partakes much of the character of the chalk hills of the before-named counties. There is, however, one idea of which the Sussex breeders are peculiarly tenacious, which is, that they can keep a much greater number of Sussex Downs than of the larger variety of Down sheep: I have heard it stated, to the amount of one-third more. But we have good judges, who, after impartial trials and great experience, do not allow more than one in twenty in favour of South Downs. My own opinion, however, is, that the fairest proportion is one in ten, and that will be found an ample allowance in favour of the breed. I must also observe, that the great improvements in the culture, and generally productive state of the land, has been lost sight of in this case; for I must claim the advantage of superior cultivation as imparting to vegetation more nutrition, and, consequently, more capability of sustaining a larger and heavier variety of stock.

I have considered the foregoing observations as necessary in guiding parties who may be commencing stock farming, and assisting those who may be desirous of improving their breeds in different districts. I shall now proceed to treat of the general management requisite at the commencement of the breeding season; having, in previous papers, spoken of the method of keeping the Ewes upon a generous and liberal diet, in order to bring them forward to the ram. I beg to observe, that the rules and manner of proceeding there alluded to will apply upon stock farms, for the management of the out-going, or that portion of the Ewes intended for sale; but for the ordinary breeding stock, it is not necessary to resort to any peculiar or expensive method of feeding; for under ordinary circumstances, the Ewes have their breeding season, which is somewhat peculiar to soil and climate, and which it does not often answer a good purpose to attempt to alter. I should, therefore, say, let them be kept fairly, and in good useful condition, with due variety and regularity in feeding, and the usual advantages of a breeding flock may be expected in return. The first thing to be considered is the selection of rams, either for the improvement of the flock, or for the maintenance of its good qualities; the former is generally, however, considered somewhat easier than the latter. I am aware it is the custom with many ram breeders (who may, possibly, be repaid for extra trouble and attention to their stock), for them to select sheep, and put them to Ewes individually, with the view of one animal correcting defects existing in the other, and which may otherwise be inherited or perpetuated by the offspring. Now, I am well aware, that in large breeding flocks, kept for profitable increase, this would be too tedious and expensive a project. I, therefore, suggest, whilst acknowledging the fact that "like begets like,"

that the improvement of a flock may be well secured by drafting the Ewes previous to turning the ram with them, and dividing them into two or more classes, placing in one class those which may be too kind, or deficient in flesh and bone, and turning with them rams calculated to remedy these defects; and in another class, those which are too coarse and unkind, and select rams for them of an opposite description; whilst a third class may also be formed, with the object of correcting any deficiency in the quality of wool, or other points, which are well known to breeders. This plan possesses great advantages; for the general character of a flock may be soon raised, at a moderate expense, merely by the extra trouble attending the separate keeping and feeding the flock during a period of about six weeks.

JOSEPH BLUNDELL.

(To be continued.)

GAPES, AND THE DISEASES CONFOUNDED WITH IT.

I AM afraid that the readers of the COTTAGE GARDENER are as tired, as, I confess, that I am of the constant discussions that arise from Dr. Horner's criticisms on my medical articles. Dr. Horner's last letter (page 224), in which he states that my experiments, related at page 127, prove the roup to be *not* contagious, shows that we regard medical evidence from points of view so widely different, and the inferences which we draw from the same facts demonstrate that our processes of reasoning are so essentially opposed to one another, that I scarcely think it probable that we shall ever arrive at the same conclusion on any subject whatever. Respecting roup, it is, therefore, useless for me to say more. I have laid the facts with which I am acquainted so fully before my readers, that they may readily draw their own inferences as to its contagious or non-contagious character.

On the subject of Gapes, however, I must be permitted to say a few words; especially as I have not hitherto replied to the numerous remarks of Dr. Horner on my statements.

The discussion has arisen from the confounding of two essentially distinct diseases, namely, Gapes caused by parasitic worms, and Croup, or inflammation of the windpipe. I repeat, two essentially distinct diseases, that could never have been confounded by any person who had closely watched the symptoms of both.

True Gapes is prevalent amongst chickens; whilst Croup usually attacks older fowls. Gapes is common in the spring and summer; Croup is more frequent during wet autumns. I have not seen a case of Gapes for some months; and Dr. Horner is quite safe in asking for specimens of the disease at this season, when it is quite certain he will not get them.

It is well known that croup in children is more prevalent in wet seasons and situations than in those that are dry; and, as might have been expected, croup in fowls was very abundant during the past rainy autumn; many cases, both living and dead, were forwarded to me, and I also had several amongst my own fowls. In all instances I found the disease yield readily to one-twelfth of a grain of tartar emetic, and warm, dry housing. One bird that I killed for examination, during the progress of the disease, exhibited no other morbid indications than a high degree of inflammation of the living membrane of the windpipe.

I have cases I never for a moment confounded with Gapes, as the manner of breathing in the two diseases is most distinctly marked; in Gapes, as its name implies, the chick is observed to open its mouth at *intervals* with a decided gape, and a muscular action of the neck, as if it were endeavouring to dislodge something from the throat. In croup, on the contrary, the bird does not gape (strictly speaking), but the mouth is kept more or less open, and there is always either a rattling noise from accumulation of

mucus in the windpipe, or that peculiar metallic trumpet-like sound which is so characteristic of croup in children.

The cases mentioned by Drs. Horner and Ranking were evidently those of croup, or simple inflammation of the windpipe; they are described as occurring in fowls (not in chickens), and as yielding readily to antimonials.

If these gentlemen will patiently wait until the spring, I have no doubt but that they will be able to discover a sufficient number of cases to induce them to modify the assertion that Gapes is only occasionally produced by parasites. I repeat, from extensive experience, and I know numbers of your readers will bear out my assertion, that *true Gapes in chickens is invariably produced by the presence of worms in the windpipe, and that spirit of turpentine, applied either directly, or by fumigation, is the most effective remedy.* At the same time, I am perfectly cognisant of the frequent existence, under other circumstances, of a simple, (and if my unprofessional readers will excuse a technical term) idiopathic inflammation of the mucous lining of the windpipe.

Dr. Horner's assertion, that the presence of parasites "is quite compatible with, yea, perhaps necessary, to health," is certainly one of the most extraordinary I ever met with; and if some professional D'Israeli shall hereafter arise, will stand a fair chance of being embalmed amongst the "curiosities of (medical) literature."

The medical profession are evidently in a state of the most benighted ignorance, for they all regard the presence of tape worms, and the other animals that infest the human body, as causing severe and sometimes fatal disease, and are in the habit of employing the most powerful medicines for their expulsion.

I cannot conclude without returning my thanks to Dr. Anthony for kindly forwarding the drawing of the worm which it would have been impossible for me to have furnished at this season of the year. Into the disagreement between him and Dr. Horner I have no inclination to enter, for I regard personal disputes as exceedingly undesirable in a public journal, and very uninteresting to the readers at large. I have, therefore, in my capacity as a regular correspondent to this journal, often refrained, even when sorely tempted, from entering into a personal discussion with my perpetual antagonist.—W. B. TEGEMEIER, *Willisden, near London.*

GROWING PEAR-TREES ON QUINCE STOCKS.

LIVING, perhaps, in the most favoured locality under the sun for the cultivation of the Pear, viz., the Isle of Jersey, it may not be irrelevant, and I hope will not be considered obtrusive by your talented correspondent, "R. E." if I submit the following remarks to the perusal and attention of your readers. There is so much soundness of argument and apparent good judgment in the article he has written and published in one of your late numbers relative to the comparative value of the free (Pear) and Quince stocks in their application to the purpose of growing this valuable and wholesome fruit, that I dare not say, "we differ in opinion." Nay, I have learned much from his article; he may, possibly, learn something from mine. And, doubtless, it may be observed in the perusal of these lines, that the object it is so desirable to prevent, *i.e.*, too great an extension of the roots, may be realised without having recourse to what I consider the troublesome practice of constantly transplanting the trees, attended with certain loss of time in a large establishment, where much ground is devoted to gardening purposes, and many hands are kept, and altogether incompatible and inconvenient in the management of small gardens.

My friends have been growing Pear-trees on Quince stocks for upwards of forty years, and I have been employed in the same way for the last fifteen. I obtained all the information I could from them, and then applied my own wits to the subject, and I have cause to be much gratified with the result of my practice; and trust I may, having shown the grounds on which I offer my opinions, write confidently and freely on a subject I am so well and

intimately acquainted with; and whilst my experience is limited to this favoured island alone, I have authority for stating that similar practice has produced similar results in many parts of the United Kingdom. In Cornwall, Devonshire, Somersetshire, Hampshire, Essex, Suffolk, and other counties, and I dare to say it may be done generally, where suitable soil and situation is afforded. I, therefore, with due deference to the opinion of "R. E.," "that until the public better understand, or better consider this question, it will be well for those who feel puzzled to grow Pears on the ordinary stock," strongly recommend the Quince stock for the cultivation of the Pear; and whilst advocating and proving its efficiency for the purpose, strongly recommend all persons about to plant Pear-trees to adopt the plan, setting aside all idea and thought

"That he who plants pears,
Plants for his heirs."

In the cultivation of the Pear on the Quince stock, it is necessary, in the first place, to procure good stocks (the Portugal variety is the best, as it grows most vigorously), which, if planted in a suitable soil in the fall of the year, will be fit for budding the ensuing August. By a suitable soil, I mean any soil that is rich, open, and moist, and in a sheltered situation. Should the soil in which it is convenient to plant them be of a stiff, retentive character, and rather dry in its nature (very dry soils in high situations will not suit), I would recommend that it should receive a good dressing of sea-sand, or lime and salt, the saline particles of which retain their moisture, and are of immense benefit to stiff soils, both as to rendering them open, and also in enriching them at the same time, by imparting to them the benefit of the salts they contain.

The stocks being planted, and having made a free and vigorous growth during the first season, I, as far as possible, use the western and south-western sides of the stocks for the insertion of the buds, as the wind is more prevalent in this quarter of the globe from these than from any other parts of the compass, the buds are thereby less exposed, and, consequently, less liable to be broken off by the wind. I do not bud until the middle or latter end of August, availing myself, if possible, of an opportunity after rain, as I always find the bark of the stocks run best at such times. I insert the buds within two or three inches of the ground (applying the common T method in the practice), as I find the buds so placed always shoot off much stronger, and upon the first year's growth much of the after success depends. All the varieties do not do equally well on Quince bottoms, but the exceptions are very few. I have subjoined a list of a few of the best varieties, with their styles of growth, and periods of maturing their fruits.

The buds having been carefully put in and tied require no further attention but looking to at the descent of the sap, so as to loosen and remove such ties as require it, and prevent their cutting the bark, paying the penalty of negligence at this period of the plant's growth, the results of which are unsightly carbuncles and disfigurements, from which the plant cannot be afterwards ridged, and which often causes stagnation in the flow of the sap, producing canker and irremediable disease.

To this particular point I would call your readers attention—"That unless a Pear-tree budded on a Quince stock is clean and freely grown it is not worth planting." The only chance of succeeding with it, is to plant it a little below the bud, so as to induce it to root in its own wood, thus annulling, to a great extent, the utility of the Quince in bringing it to an early bearing state.

In December, I carefully head the stocks down three inches above the bud, slanting the cut to the northward, so as to carry the wet from the bud; I, at the same time, remove the remainder of the ties. When the buds shoot off in the spring, I tie them carefully up to the upper part of the stock, pinching out the ends of the strongest shoots in the beginning of May: it must not be done later, as it would be useless, not allowing time for the perfection of the young wood, which, if not properly ripened, must be cut away at the next season's pruning.

In the first year's pruning, I cut the shoot or shoots short, the central shoot being left longer than the others, and being careful in pruning the side-shoot or shoots to have an eye to the future formation of the tree, by leaving

the utmost and foreright buds in the right direction. The second year's pruning and growth so far forms the strongest of the trees, that they are prepared to be removed to the position in the ground or garden they are intended to occupy; and as the principal part of the stocks are grown from cuttings, the great disadvantage of strong roots is, and has been, obviated by this means of preparing the stocks, so that the transplanting is attended with very little trouble, and the replanting is rendered equally easy. In the planting, should the ground be moist and rich, I plant the trees at the same depth as they were previously planted and had grown in the quarter; but if, on the other hand, it is rather dry, I plant a little deeper, as I find they do better by being so planted, and roots often proceed from the Pear wood as well as from the Quince. I find old lime-rubbish and cinder-ashes to be excellent materials for dressing the surface with, as they induce the stock to throw out a large quantity of fibrous roots, and they are the alimentary and nutritive organs of the tree, in the fruit-bearing state, during many after years. I generally prune the roots previously to planting, cutting under, and mixing a small proportion of well rotted manure with the soil in the planting, more particularly so if the ground has not been previously prepared by trenching, &c.

The trees being planted either in rows at ten feet apart either way, over a piece of ground, or round the quarters of a vegetable garden (the usual plan), it is desirable to get as much growth as possible from them during the first two or three years by judicious pruning. This is easily effected; the wood being vigorous, you have only to adopt the plan which is most applicable to your situation, and train the trees accordingly, either as espaliers in the perpendicular and horizontal style of training (by far the best plan for Pears, either in this way or on walls, as it throws them into early and productive bearing), or as pyramidal trees, or as dwarf standard, or Quenouille trees, or as standard, or standard-trained trees, run up on their own wood; in the practice of either of which plans I prune with care until the tree is formed, shortening all the shoots, so as to form fruiting spurs, with the exception of the leading and such shoots as are required to make and maintain the formation and appearance of the tree, which are pruned from nine to twelve inches long. The trees grow spontaneously, and produce abundant crops, which are valuable in these islands as articles of sale,—one hundred *Chaumontelle* Pear-fruit, weighing one hundred pounds weight, readily realizing the handsome sum of £5. It is not unusual to see them so fine; most gardens here produce some such fine fruit, and I once saw a Pear of this particular sort which weighed twenty-three ounces. Smaller fruit of the same sort realize lower but almost proportionate prices, according to their weight and appearance. The other sorts of Pears, being some of them smaller, and produced in much larger quantities, besides being ready for sale when there are larger collections of fruit in the market, are sold at much lower prices, but, nevertheless, make a good return.

The period of the tree's duration in a productive state is from twenty to twenty-five years, requiring to be often renewed after that period; for, having produced quantities of fruit during the preceding years, and the wood having been constantly spurred back, has become more or less deteriorated. The roots may also be decayed, or have, possibly, got into the cold subsoil, which is not suitable for them. Whichever may be the case, they will, if they have received one-third of the care it is necessary to bestow on free stocks, and have thrived under it, be in no way indebted to their owners, and should be grubbed-out, to be replaced by young trees.

Thus the greatest of all advantages attending growing Pear-trees on Quince stocks are—early and great productiveness; whilst they occupy so small a space of ground that they soon pay for themselves and the space they occupy, besides handing a handsome per centage over to their owners for the little trouble and care necessary to keep them in order. Who would grow Pears on free (Pear stocks) in preference to Quince, when such results may and are realised? My reasoning powers induce me to think, "that to grow Pear-trees in such a way as to last a short and useful space of time, is far better than to take the

chance of growing fruit for futurity;" the risk run in growing them on the free stock.

I subjoin a list of a few of the best and most free-growing varieties, with the periods of the fruit's maturity, which, of course, varies a little according to the seasons, and trust the foregoing article may be interesting and instructive to some of your readers, as well as assist in settling an unsettled question, as wherever a Quince-tree will grow, a Pear-tree may be grown on a Quince stock.

NAME.	STYLE OF GROWTH.	PERIOD OF MATURING FRUIT.
Citron des Carmes	Free	July to August
Windsor	Very Strong	August
Jargonelle	Free	August
William's Bon Chretien	Very Strong	September
Beurré d'Amans	Very Strong	Sept. to Oct.
Gracoli	Strong	October
Louise Bonne de Jersey	Very Free	October
Brown Beurré	Free	October
Marie Louise	Indifferently	October
Duchesse d'Angouleme	Free	Oct. to Nov.
Duchesse d'Orleans	Strong	Oct. to Nov.
Miel de Waterloo	Free	Oct. to Nov.
*Cressanne	Free	Oct. to Nov.
Beurré Diel, or Royal	Very Strong	Nov. to Dec.
Napolcon, or Charles d'Autriches	Free	Nov. to Dec.
Glout Moreau	Strong	Nov. to Jan.
Colmar d'Arenberg	Strong	December
*Colmar	Free	Nov. to Dec.
*Passe Colmar	Free	Dec. to Jan.
Chaumontelle	Free	Dec. to Jan.
Knight's Monarch	Free	Nov. to Jan.
Winter Nels	Free	Dec. to Jan.
Beurré Dufom	Strong	Jan. to Feb.
Beurré Rance	Strong	Jan. to March
Easter Beurré, or Bergamot de la Pentecôte	Indifferent	March to May.
Uvedale's St. Germain, or Belle de Jersey	Strong	Baking or stewing
Gilgil	Strong	Ditto

Of the twenty-seven varieties here enumerated, which are all of the best and most useful descriptions in their seasons, there are but two which do not thrive luxuriantly on the Quince stock. The varieties marked with an asterisk require a wall: an eastern or a western aspect suits them well. Many of the other varieties produce finer fruit when placed against walls, but they do not absolutely require it.—C. B. SAUNDERS, *Cæsarean Nursery, Jersey.*

THE POUTER PIGEON.

WITH regard to the English Pouter, I believe no fancier ever saw the crop too large, provided it was of the right shape, viz., globular; although large, it is, nevertheless, neat. A large crop, slack-winded, is a great fault; fanciers do not strive to get huge crops in shape like three-cornered-cocked hats; but if they can get them round, they care not how huge they are called, particularly if it has a bill which marks it in the shape of a half-moon, well known to fanciers.

What fancier ever saw a Pouter with too slender a girth? Unfortunately, in some measure, this grand property is lost; fanciers complaining that they have to take both hands to them, whereas formerly, comparatively speaking, to use an old term, the girth would pass through a "wedding ring." The Pouter fanciers are exerting their utmost to restore it, so that the Pouter may appear like a "Tumbler" in hand. The smaller the girth, greater is the contrast given to the beautiful shape of the whole bird.

Above all, what fancier ever saw an English Pouter too long in the legs? It is possible a Pouter may fall short of length of body, or feather, but it is utterly impossible to breed a Pouter with legs too long; the best Pouter fanciers that ever lived have tried at it. Moore, in 1735, says, length of leg, seven inches. Mayor, in 1765, length of leg, some of them wanting a mere trifle of seven inches-and-a-quarter. In our day, "talk is cheap," and we hear of Pouters seven inches-and-a-half in legs. It is one thing to hear and another thing to see. I believe Pouter fanciers will think that I am going too far when I say it is possible, but very improbable, that in England a Pouter might be found that would measure seven-and-a-half inches in the leg; at the same time, I do not believe, in a thousand years they will breed one eight inches in length of leg; even if it was

possible, the legs cannot, by any possibility, be too long. The body, flight, and tail, might be too short.

The epitome of excellence in an English Pouter is made to consist as follows:—

1. Length of body.
2. Length of legs.
3. Neatness of crop.
4. Slenderness of girth.
5. Beauty of feather.

Any combination of three of these properties out of the five in a Pouter, shewn against another, must, if rightly and justly awarded, take the prize; for instance, one Pouter shewn against another, supposing one to take the first three properties, and the other to take the last two, to the former the prize ought to be awarded. It is quite immaterial which of the three properties a Pouter takes out of the five to be awarded the prize; and this will, or ought to prevail, at Metropolitan, Birmingham, and every other Show, if rightly awarded.

If persons prefer Blue Rocks to Almond Tumblers, Skinums to Carriers, or common house Runts to English Pouters, by all means let them do so, but I cannot agree with them, or admire their taste. In all shows, whether agricultural, horticultural, poultry, or pigeon, certain well-defined rules must be clearly laid down, or no judges can act in unison, or give satisfaction.—JOHN MATTHEWS EATON, 7, Islington Green, London.

EASY MODE OF EXCLUDING FROST.

It may interest some of your readers, who, like myself, have only a cold pit or frames for preserving half-hardy plants during winter, to know that I succeeded last year in keeping out frost by burning one or two floating night lights* under a plate of iron, about a foot in diameter, supported about an inch above the flame, which I found radiated sufficient heat for the purpose. I used *castor oil* (costing, wholesale, about 4d. per pound), which is so free from smell, and burns so purely, that I have used it in a sick room for three months, and at present burn it all night in my bedroom.

I did not observe any injurious effect from gases generated by the lamp, such as you seemed to fear in your reply to "J. S. K.," page 192; but if this were found to be the case, the lamp could be burned in a close iron box, and the fumes carried off in a small pipe.—A. D. A.

[The suggestion at the conclusion of this communication obviates our objection. The iron box might be made like a gas stove, with a tube passing the whole length of the pit, so that scarcely any heat would be lost. There need be no door to the box, but the bottom be made to take on or off in the manner of a pill-box lid.—ED. C. G.]

SEA WEEDS.

(Continued from page 15.)

DASYA.—Ag.

"FROND filamentous; fructification two-fold on distinct plants—1, ceramidia, containing a tuft of pear-shaped spores; 2, lanceolate pods (stichidia), containing tetra-spores ranged in transverse bands."—Harvey. Name signifying hairy.

1. DASYA COCCINEA (Scarlet).—Stems rather thick and hairy, branched, the branches twice winged. This is one of our most lovely sea plants; the colour varying from pale pink, in the early stages of its growth, to bright rosy-scarlet, and then to deep crimson-brown. In this last state it does not adhere well to paper. It is a summer plant, and annual.

2. D. OCELLATA (Eyed).—This lovely little thing is found on rocks covered with mud, near low-water mark. It is rare, though Mrs. Griffiths has found it abundantly on the pier at Torquay. It is in little tufts only one or two inches high. The minute branches at the tips of the fronds are so crowded that the plant looks something like a tuft of

* The best are German manufacture, a wick inserted in a thin slice of cork, and cost only 6d. for a large box.

little brownish-red feathers, with eyes; hence its name (*ocellata*).

3. D. ARBUSCULA (Shrubby).—"The stems much branched." They vary from two to four inches in height, are of a red-brown, and the substance rather soft. "Not uncommon on the shores of Ireland and Scotland."—Harvey.

4. D. VENUSTA (Lovely).—I have never had the pleasure of seeing this plant. Harvey speaks of it as cast on shore in summer, and found in Jersey by Miss White and Miss Turner. "Annual. Very rare. Stem 3—4 inches high, as thick as a hog's bristle, bare of ramuli, but all the branches and their divisions clothed with very slender, hair-like, single-tubed ramuli. Colour a fine rose-red; substance very flaccid and tender; closely adhering to paper. A beautiful species."—Harvey.

ORDER 8.—LAURENCIACEÆ.

"Rose-red or purple Sea Weeds."—Harvey.

1. BONNEMAISONIA.—Ag.

Named after M. Bonnemaïson.

BONNEMAISONIA ASPARAGOIDES (Asparagus-like).—A very

beautiful weed, growing on rocks. The frond is from four to twelve inches long, and much branched; the branches alternate, with little slender ramuli. The colour, when cast on shore, a fine scarlet, or rather rose, becoming darker, or crimson, in drying. Harvey remarks that "those plants of *B. asparagoides* found in the west of Ireland are darker, and also become darker in drying; while in those which are from the east coast of Ireland and south of England the colour fades in drying." I have observed this tendency to fade in Scotch specimens also. The most beautiful specimens I have seen, as regards colour, were some which I found on the Northumberland coast at Bamborough, opposite the Farn Islands. It was really a very pretty sight to see them come floating in with the advancing tide, and I watched and waited long that none might escape me, as they were not very plentiful, and it was only on that one day that I found them. It is a summer plant, and annual. The specimen from which our plate is taken is from Ireland, and rich in capsules, which contain a tuft of spores.

2. LAURENCIA.

Name in honour of M. de la Laurencia.

1. LAURENCIA PINNATIFIDA (Deeply-lobed).—This plant is also annual, and grows on rocks. It is common and very

variable in its appearance—sometimes of a yellow-green, at others brown or purple. The fronds are from one to twelve inches high; substance cartilaginous. "It has a hot, biting taste, and in Scotland is called Pepper dulse."

L. CESPITOSA (Tufted).—Fronnd roundish-winged, pyramidal; ramuli numerous, often crowded, tapering to the base. Growing on stones. Annual. Summer. Common. Colour dark purple—sometimes, when exposed to the sun, greenish-yellow.

3. *L. OBTUSA* (Blunt).—Parasitic on large algæ. Annual. Not uncommon in England and Ireland, but more so in Scotland. The substance is tender, and the plant soon breaks into pieces if left long in fresh water. The fronds are tufted, rather crowded, from three to six inches long. I have specimens from the Cumberland coast, and one from *Jaffa*!

4. *L. DASYPHYLLA* (Hair-leaved).—"Fronnd filiform, irregularly branched; ramuli short, club-shaped, obtuse, very much attenuate at base; colour pale pink."—*Harvey*.

5. *L. TENUISSIMA* (Thinnest).—On rocks and algæ. Very rare. Colour pale purple, or red.

3. CHRYSYMENTIA.—*J. Ag.*

1. *CHRYSYMENTIA CLAVELLOSA* (Club-spotted).—The frond of this delicate and lovely weed is gelatinous, and from three to twelve inches high, very much branched, and of a beautiful crimson-pink. When placed in fresh water for a time it assumes a yellow or orange tint, whence its generic name, from two words, signifying golden and a membrane. It is not very common, but I have frequently had it from the Isle of Man, through the kindness of my friend, Miss Heslop.

2. *C. ORCADENSIS* (Orkney).—"At Skail, Orkney, Miss Watt. The specimens yet seen of this supposed species are insufficient to establish its character fully."—*Harvey*.

4. CHYLOCLADIA.—*Grev.*

"Fronnd tubular, constricted at regular intervals, and divided into chambers. Name from two words, signifying juice and a branch."

1. *CHYLOCLADIA OVALIS* (Oval).—On rocks, sometimes on other algæ. An annual, and not uncommon on the English and Irish shores. From two to ten inches high; cartilaginous; the branches set with oval ramuli of a purplish colour.

2. *C. KALIFORMIS* (Kali-shaped).—The substance is gelatinous, and the form that of a tube constricted at intervals, with the branches in whorls. Fronds from four to eighteen inches long; colour purplish-red, often a pale greenish-yellow. Frequent on rocks and algæ.

3. *C. REIFLENA* (Bent-back).—Fronnd of a purple colour, and membranaceous. The lower branches are arched, and attach themselves by short processes. This plant is very rare. A specimen I have from Mrs. Ralfs is the only one I have seen. It has been found near Ilfracombe.

4. *C. PARVULA* (Little).—A parasite on the smaller algæ. Gelatinous and slender; colour a fine red.

5. *C. ARTICULATA* (Jointed).—Like the preceding, this plant springs from a tuft of fibres. It is very much branched and bushy; colour a pink-red, and the frond filled with thin gelatine. S. B.

(To be continued.)

POULTRY NOTES. DISEASED PIGEONS.

A CORRESPONDENT wished to know how to treat the disease termed "going light," when Pigeons are ill, moping about inanimate, and gradually wasting away. I have always found fat of some sort to be an excellent restorative; for instance, a few pills of fresh butter, suet, or pork-fat, about the size of a pea, put down their throats on alternate days, a few times; and, if practicable, allow them to run in the garden. Though Pigeons are not carnivorous, I have known some exceedingly fond of ham-fat, which they devoured greedily, and apparently much to their well-being.

Your correspondent seems to doubt the fact that Pigeons

are fond of green food. I am well aware that those that have never had an opportunity of pecking about in a garden, and are, consequently, ignorant of such food, will necessarily express no fondness for salad; but Pigeons are, nevertheless, naturally very fond of some plants, such as young peas, lettuces, savoys, cabbage, and the young tops of Swede turnips. Rough-leaved plants, such as mustard and white turnips, they reject.

SPANGLED HAMBURGH FOWLS.

IN giving the Lancashire Rules for judging the Pheasant Fowls, or, as you call them, Spangled Hamburgs, I beg to say it is a mistake to call those therein named Creels, Silver Pencilled, for by carefully reading that rule you will find them to be what I suspect you would condemn as bad Silver Spangled; they are, in other words, White-necked Silver Pheasants; their difference from the Moon Pheasants consists in their having white necks and breasts; and the black markings being simply designated spots, not moons, the Moon Pheasants having dark markings in their hackles, and moons (round spots) on their breasts; thus you will perceive there are four classes of Pheasant Fowls, or Spangled Hamburgs, Golden Pheasants, Copper, or Red Moon Pheasants, Creels, or Silver Pheasants, and Silver Moon Pheasants. Now, as no Poultry Book, that I have seen, has collected all the rules for judging these varieties, consequently, a judge that prefers, or, perhaps, only knows one, may be excused for having a predilection when both are shown in one class.

COMBS OF DORKINGS.

I FEAR my remarks on the combs of Dorkings, published some time back, were misunderstood. When I said they ought to be Rose-combed, I meant the old Dorkings of white plumage, the fowls originally bred at Dorking, in Surrey. The single-combed birds that occasionally appear among them, I believe to arise from the practice formerly so frequent of crossing with a game cock to improve a worn-out stock. The Grey, I am aware, may be either single, cuppel, or rose-combed, according to the pleasure of the breeder, but as these are descended from the old Sussex fowl, I do not consider them as true Dorkings, even though they have generally assumed the name.

CHICKENS FROM PULLETS & COCKERELS.

YOU wished to know the sex of chickens bred from birds of the preceding year. My Shanghaes, from a cockerel of Anster Boms, hatched in March, 1852, and pullets of April and May, of the same year, have produced as follows:—First broods, thirty-three chicken, sixteen cockerels, and seventeen pullets; second broods, twenty-five chicken, seven cockerels, and eighteen pullets.

ROUP.

THE various discussions on this malady of the poultry-yard, concerning its contagion, or non-contagion, appear rather to have passed the bounds ofanity. I believe there is some truth on both sides, thus—influenza, or any cold, is at once set down as Roup; and it is here, I think, the error originates.

Putrid Roup I consider similar to glanders in horses, and very contagious; still I am inclined to believe, that even were a roup fowl placed in a healthy run, and clean, airy fowl-house, where there was no predisposing cause, the contagion *might not* spread, so powerful are circumstances; but I should, by no means, like to try the experiment with valuable fowls.—B. P. BRENT, *Bessels Green, Sevenoaks*.

POULTRY EXHIBITIONS.

CORNWALL POULTRY EXHIBITION.—This was held in the Corn Market, Penzance, on the 27th and 28th of December. The following is the

PRIZE LIST,

in reading which it should be borne in mind, that where two classes exist for the same breed of fowl, the first-mentioned

are birds above a year old, and the last those hatched in 1853.

SPANISH.—Second prize, Mr. J. Fox, Rosevale, Penzance. Ditto.—Second prize, Mr. W. Lawrence, Rosemorran.

COLOURED DORKINGS.—First prize, G. Williams, Esq., Trevince. Ditto.—First prize, G. Williams, Esq., Trevince. Second prize, W. Bolitho, Esq., Chyandour.

WHITE DORKINGS.—Second prize, A. Smith, Esq., Scilly. Ditto.—First prize, A. Smith, Esq., Scilly. Second prize, ditto.

BUFF AND CINNAMON SHANGHAES.—First prize, Mr. W. Lawrence, Rosemorran. Second prize, Mr. J. R. Branwell, Penzance. Ditto.—First prize, Rev. W. W. Wingfield, Gulval. Second prize, Mr. T. Gittus, Goldsithney, and Mr. Welch, Penzance.

BROWN AND PARTRIDGE-FATHERED SHANGHAES.—Second prize, Mr. T. Gittus, Goldsithney. Ditto.—First prize, Mr. E. Burton, Truro.

WHITE SHANGHAES.—Second prize, Mr. W. Lawrence, Rosemorran, Gulval. Ditto.—First prize, Rev. W. W. Wingfield, Gulval. Second prize, Mr. W. Lawrence, Rosemorran.

MALAYS.—First prize, Mr. Thomas Mayne, Penzance.

GAME FOWL.—First prize, E. H. Rodd, Esq., Penzance. Second prize, Rev. W. W. Wingfield, Gulval. Highly commended, ditto. Ditto.—First and second prizes, Rev. W. W. Wingfield, and P. Grenfell, Esq.

GOLDEN-PENCILLED HAMBURGH.—Second prize, P. Grenfell, Esq., Gulval (young birds).

SILVER-PENCILLED HAMBURGH.—Second prize, P. Grenfell, Esq., Gulval. Ditto.—Second prize, P. Grenfell, Esq.

SILVER-SPANGLED HAMBURGH.—Second prize, P. Grenfell, Esq., Ditto.—Second prize, Mr. E. Burton, Truro.

POLANDS (Black with white crests).—Second prize, Mr. J. Fox, Rosevale.

GOLDEN POLANDS.—First prize, Mr. E. Burton, Truro. Ditto.—First prize, Mr. E. Burton, Truro.

SILVER POLANDS.—Second prize, G. Williams, Esq., Trevince. Ditto.—Second prize, Mr. J. Fox, Rosevale.

POLANDS (Any other variety).—First prize, Mr. Lawrence, Rosemorran.

BANTAMS.—First prize, G. Williams, Esq. (Silver-laced). First prize, Mr. E. Burton, Truro. (White.)

GEESE.—First prize, Rev. W. W. Wingfield, Gulval. Second prize, G. Williams, Esq. Third prize, Mr. H. Trembath, junr., Bosereage, Gulval. Ditto.—First prize, Rev. W. W. Wingfield, Gulval. Second prize, ditto.

WHITE AYLESBURY DUCKS.—First prize, J. S. Bedford, Esq., Pendrea. First prize, Mr. E. Burton, Truro. (Young birds.)

ROUEN DUCKS.—First prize, Rev. W. W. Wingfield. Second prize, T. S. Bolitho, junr., Esq., Penalverne, Penzance.

DUCKS (Any other variety).—First prize, J. S. Bedford, Esq., Pendrea. Second prize, A. Smith, Esq., Scilly.

TURKEYS.—First and second prizes, G. Williams, Esq., Trevince. Ditto.—First prize, G. Williams, Esq.

PIGEONS.—First prize, Mr. E. Burton, Truro (Black Carriers); ditto, ditto (White Pouters); ditto, ditto (Buff Jacobines); ditto, ditto (Yellow-shouldered Turbits, crested; ditto, ditto (Silver Owls). First prize, Mr. J. Fox, Rosevale (Nuns); ditto, ditto (Fawn Tumblers). First prize, G. Williams, Esq., Trevince (Runts); ditto, ditto (Almond Tumblers). First prize, Rev. W. W. Wingfield (Fantails); ditto, ditto (Arohangel). First prize, Rev. T. P. Phillpotts, Portgwidden (Trumpeters). Highly commended.—Rev. W. W. Wingfield (Runts); Mr. C. Ellis, Hayle (Fantails); Mr. E. Burton, Truro (Silver Turbits); Rev. W. W. Wingfield, Gulval (Nuns); and Mr. E. Burton, Truro (Nuns). Commended.—Mr. H. Baynard (White Fantails); Mr. E. Burton, Truro, ditto; Mr. J. Fox, Rosevale (White Jacobines); ditto (Trumpeters); ditto (Owls); and Mr. E. Burton, Truro, (Almond Tumblers).

EXTRA STOCK.—First prize, W. Bolitho, Esq., Chyandour (Peacock and Hen). First prize, Rev. W. W. Wingfield, Gulval (coloured Call Drake and Duck). First prize, E. H. Rodd, Esq., Penzance (Cock and two Hens, common Pheasants).

Some notes promised on this Exhibition have not yet reached us.

HONITON AND EAST DEVON POULTRY EXHIBITION.—The Second Annual Exhibition of the Honiton and East Devon Association for the Improvement of Domestic Poultry was held at Honiton, on Wednesday and Thursday, the 28th and 29th December, in the Market House and Poultry Market adjoining, which had been covered in with glass, and fitted up for the occasion, and everything done to render it comfortable for the birds and commodious for the visitors. The weather, unfortunately, was very unpropitious, a heavy snow-storm having fallen on the day previous to the Show, followed by a severe frost, which deterred many from visiting the Exhibition. But, notwithstanding, the attendance was very good on the first day, and on the second the numbers were largely increased. 418 pens of birds were entered for competition, and the quality of the classes, with the exception of one or two, was such as has rarely been brought together at any Provincial Show.

The Pen of *Spanish*, which took the first prize in class 1, contained hens of surpassing excellence; and the Cockerel in the first prize pen of Class 2 was a bird of considerable merit. The *Coloured Dorkings* were particularly fine. The *Cochin-Chinas* were, as usual, the most numerous. The *Buff Chicken* class was, however, the centre of attrac-

tion, as it contained the rival pens of Captain Snell, of London, and Mr. Channing, of Heavitree; the former gentleman having, through the local papers, challenged his birds against those of all the amateurs in Devon and Cornwall, which was accepted by the latter. The pens exhibited by both gentlemen were unusually fine, and although Capt. Snell carried off the palm, Mr. Channing may well be proud of his birds; and many of the other pens in this class were of sufficient merit to have secured for them a prize at almost any local Show. The *Malays* were a very good class, and showed that in spite of the favour which their more recently imported neighbours have enjoyed, they still retain some kind patrons and friends. The Birmingham Prize birds, "Wallace" and "Lord Lilliput," appeared in this class.

The *Game Fowls*, in all their varieties, were admirably represented, particularly in the *Chicken* class.

The *Hamburghs*, with their gay and varied plumage, were, in all their classes, of great merit.

The *Polands* were few in number, and, with the exception of two or three pens, not remarkable either for size or beauty.

The *Turkeys*, *Geese*, and *Ducks* were all good, particularly the latter. In the *Aylesbury* class the competition was unusually severe.

The *Bantams* comprised almost every variety, and were well represented, and among them was a pen of *Silky Japan Poultry*.

The *Pigeons* were numerous, and, from their beauty and rarity, formed a very interesting part of the Exhibition.

The prizes for *Dead Poultry* were a new feature. The entries were, however, comparatively few, and the poultry not of first-rate quality. The Exhibition closed at four o'clock in the afternoon of Thursday, and, with very few exceptions, the birds were dispatched to their respective homes the same evening. The Judge was E. Hewitt, Esq., Sparkbrook, near Birmingham.

The following is a list of the awards:

SPANISH.—Class 1.—Cock and two Hens. (8 pens.) 8. First prize, James E. Marshall, Belmont, Taunton, Somerset. 1. Second prize, Boughton Kingdon, Upper Paul-street, Exeter. (Whole class meritorious.) Class 2.—Cock and two Pullets, chicken of 1853. (12 pens.) 10. First prize, Miss Dyott, 2, Torwood Mount, Torquay, Devon. 11. Second prize, W. J. Square, 14, Portland Square, Plymouth.

DORKING (COLOURED).—Class 3.—Cock and two Hens. (9 pens.) 21. First prize, J. F. Pearce, Lower Sleuton, Whimple, Devon. 26. Second prize, Mrs. Brunel, Watcombe, Torquay, Devon. Class 4.—Cock and two Pullets, chicken of 1853. (13 pens.) 31. First prize, J. R. Rodbard, Aldwick Court, Wrington, Bristol. 40. Second prize, J. H. Townsend, Ashfield, Honiton, Devon.

DORKING (WHITE).—Class 5.—Cock and two Hens. (4 pens.) 50. First prize, C. Edwards, Brislington, Bristol. 51. Second prize, Miss Wilcox, Nailsea Court, Bristol. Class 6.—Cock and two Pullets, chicken of 1853. (2 pens.) 52. First prize, Miss Fanny Patteson, Feniton Court, Honiton, Devon. (Second prize withheld.)

COCHIN-CHINA (CINNAMON AND BUFF).—Class 7.—Cock and two Hens. (13 pens.) 54. First prize, W. L. Channing, Heavitree, Exeter. 62. Second prize, Cyrus Clark, Street, Glastonbury, Somerset. Class 8.—Cock and two Pullets, chicken of 1853. (32 pens.) 92. First prize, Capt. Snell, St. Swithin's Lane, London. 91. Second prize, W. L. Channing, Heavitree, Exeter. (The whole class highly meritorious.)

COCHIN-CHINA (WHITE).—Class 9.—Cock and two Hens. (6 pens.) 102. Second prize, F. J. Coleridge, The Cottage, Ottery St. Mary, Devon. (The first prize withheld.) Class 10.—Cock and two Pullets, chicken of 1853. (4 pens.) 108. First prize, Cyrus Clark, Street, Glastonbury, Somerset. 107. Second prize, James Turner, Northbrook, Exeter.

COCHIN-CHINA (BLACK, BROWN, AND PARTRIDGE).—Class 11.—Cock and two Hens. (4 pens.) 109. First prize, Miss Dyott, 2, Torwood Mount, Torquay, Devon. (Black.) 110. Second prize, Mrs. Madge, Gittisham, Honiton, Devon. (Partridge.) Class 12.—Cock and two Pullets, chicken of 1853. (19 pens.) 125. First prize, Capt. Snell, St. Swithin's Lane, London. (Partridge.) 124. Second prize, Thomas Bridges, Croydon, Surrey. (Partridge.)

MALAY.—Class 13.—Cock and two Hens. (6 pens.) 132. First prize, Charles Ballance, 5, Mount Terrace, Taunton, Somerset. 135. Second prize, William Manfield, Dorchester. Class 14.—Cock and two Pullets, chicken of 1853. (6 pens.) 138. First prize, Charles Ballance, 5, Mount Terrace, Taunton, Somerset. 140. Second prize, Edmund Stamp, Honiton, Devon.

GAME.—Class 15.—Cock and two Hens. (16 pens.) 145. First prize, J. R. Rodbard, Aldwick Court, Wrington, Bristol. 156. Second prize, Charles Edwards, Brislington, Bristol. (The whole class meritorious.) Class 16.—Cock and two Pullets, chicken of 1853. (12 pens.) 168. First prize, J. F. Mortimer, Mill-street, Plymouth, Devon. 170. Second prize, Edmund Timms, Stoke Bishop, Bristol. (The whole class unusually meritorious.)

GOLDEN-PENCILLED HAMBURGH.—Class 17.—Cock and two Hens. (9 pens.) 172. First prize, Mrs. Devenish, Honiton, Devon. 175. W. W. Rowe, Milton Abbot, Tavistock, Devon. Class 18.—Cock and two Pullets, chicken of 1853. (6 pens.) 181. First prize, Miss F. Patteson, Feniton Court, Honiton, Devon. 185. Second prize, Charles Hoxley, Norwood House, Honiton, Devon.

GOLDEN-SPANGLED HAMBURGH.—Class 19.—Cock and two Hens. (9 pens.) 193. First prize, Charles C. TEMPLER, Bridport, Dorset. 192.

Second prize, Charles C. Temyler, Bridport, Dorset. *Class 20.*—Cock and two Pullets, chickena of 1853. (8 pens.) 198. First prize, W. K. Sprague, The Quarry, Paington, Devon. 201. Second prize, C. C. Temyler, Bridport, Dorset. (An exceedingly good class.)

SILVER-PENCILLED HAMBURGH.—*Class 21.*—Cock and two Hens. (7 pens.) 204. First prize, F. H. Aberdine, Honiton, Devon. 208. Second prize, W. W. Rowe, Milton Abbot, Tavistock, Devon. *Class 22.*—Cock and two Pullets, chicken of 1853. (6 pens.) 212. First prize, F. H. Aberdine, Honiton, Devon. 211. Second prize, Miss F. Patteson, Feniton Court, Honiton, Devon.

SILVER-SPANGLED HAMBURGH.—*Class 23.*—Cock and two Hens. (9 pens.) 222. First prize, C. C. Temyler, Bridport, Dorset. 221. Second prize, Charles Edwards, Brislington, Bristol. (The whole class well represented.) *Class 24.*—Cock and two Pullets, chicken of 1853. (9 pens.) 230. First prize, Frank Page, Tor, Torquay, Devon. 232. Second prize, C. C. Temyler, Bridport, Dorset.

BLACK POLAND (WITH WHITE CRESTS).—*Class 25.*—Cock and two Hens. (3 pens.) 236. First prize, James P. Hine, Thickethorn, Ilminster, Somerset. 237. Second prize, James Newick, Hinton St. George, Ilminster, Somerset. *Class 26.*—Cock and two Pullets, chicken of 1853. (3 pens.) 239. Second prize, Henry Hine, Bedford Brewery, Plymouth, Devon. (First prize withheld.)

GOLDEN POLAND.—*Class 27.*—Cock and two Hens. (3 pens.) 243. First prize, Robert H. Bush, Liffield House, Clifton, Bristol. (Second prize withheld.) *Class 28.*—Cock and two Pullets, chicken of 1853. (5 pens.) 248. First prize, Cyrus Clark, Street, Glastonbury, Somerset. 245. Second prize, Charles Edwards, Brislington, Bristol.

SILVER POLAND.—*Class 29.*—Cock and two Hens. (3 pens.) 251. First prize, Cyrus Clark, Street, Glastonbury, Somerset. 240. Second prize, W. W. Rowe, Newton Abbot, Tavistock, Devon. *Class 30.*—Cock and two Pullets, chicken of 1853. (3 pens.) 252. First prize, Charles E. Coleridge, Eton College. 253. Second prize, Charles Edwards, Brislington, Bristol.

BANTAMS (GOLD AND SILVER-LACED).—*Class 31.*—Cock and two Hens. (10 pens.) 258. First prize, Joseph Goodenough, Godmanstone, Dorset. 260. Second prize, J. G. Gully, Queen-street, Exeter.

BANTAMS (BLACK, WHITE, AND ANY OTHER VARIETY).—*Class 33.*—Cock and two Hens. (18 pens.) 232. First prize, William Connett, 270, Hight-street, Exeter. 281. Second prize, William Connett, 270, Hight-street, Exeter.

TURKEYS.—*Class 33.*—Cock and one Hen. (13 pens.) 291. First prize, Charles Edwards, Brislington, Bristol. 285. Second prize, Mrs. Griffin, Holmsley Farm, Monkton, Honiton, Devon. (Competition good.)

GESE.—*Class 34.*—Gander and one Goose. (5 pens.) 295. First prize, Thomas Valentine, Uppottery, Honiton, Devon. 300. Second prize, W. W. Rowe, Milton Abbot, Tavistock, Devon.

DUCKS (WHITE AYLESBURY).—*Class 35.*—Drake and two Ducks. (13 pens.) 311. First prize, W. W. Rowe, Milton Abbot, Tavistock, Devon. 318. Second prize, Miss Wilcox, Naislea Court, Bristol.

DUCKS.—*Class 36.*—Drake and two Ducks. (10 pens.) 322. First prize, T. J. Bremridge, Penrose Villa, Heavitree, Exeter. 326. Second prize, W. W. Rowe, Milton Abbot, Tavistock, Devon.

PIGEONS.—*Class 37.*—Carriers. (7 pens.) 329. W. L. Channing, Heavitree, Exeter. *Class 38.*—Tumblers. (4 pens.) 336. W. L. Channing, Heavitree, Exeter. 339. Commended.—J. B. Chune, Coalbrookdale, Salop. *Class 39.*—Nuns. (8 pens.) 341. W. L. Channing, Heavitree, Exeter. *Class 40.*—Archangels. (3 pens.) 350. J. B. Chune, Coalbrookdale, Salop. *Class 41.*—Jacobines. (5 pens.) 353. W. L. Channing, Heavitree, Exeter. *Class 42.*—Fantail. (9 pens.) 361. Charles Edwards, Brislington, Bristol. *Class 43.*—Runts. (2 pens.) 365. Rev. E. E. Coleridge, Buckerell Viarage, Honiton, Devon. *Class 44.*—Any other variety. (2 pens.) 397. J. B. Chune, Coalbrookdale, Salop. (Australian Pouter.) 386. Highly commended.—Charles Bluett, Taunton, Somerset. (Magpies.)

DEAD POULTRY.—*Class 45.*—Turkey. (5 entries.) 389, and 390. First and second prizes, Mrs. Griffin, Holmsley Farm, Monkton, Honiton, Devon. *Class 46.*—Cockerels. (6 entries.) 397. First prize, Wm. Brown, Red Gate Farm, Shute, Devon. 394. Second prize, Mrs. Vern, Upton Cottage, Payenhury, Devon. 396. Highly commended.—James Conley, Honlet, near Honiton, Devon. *Class 47.*—Pullets. (4 entries.) 401. First prize, Dr. Rogers, Honiton, Devon. 400. Second prize, Mrs. Banfield, Wadhayes Farm, near Honiton, Devon. *Class 48.*—Goose. (5 entries.) 404. First prize, Clement Griffin, Luppitt, Devon. 406. Second prize, Thomas Griffin, Luppitt, Devon. *Class 49.*—Ducks. (3 entries.) 409. First prize, Clifford Shirreff, Yardbury, Colyton, Devon. 410. Second prize, Thomas Griffin, Luppitt, Devon.

SALISBURY AND WESTERN COUNTIES.—This took place on the 5th and 6th instant. Very great credit is due to the Honorary Secretary for the success attending it. The birds were exceedingly well attended to, and the rooms of the Council Chamber afforded a well-lighted and comfortable arena. Mr. Andrews, of Dorchester, was to have been one of the Judges, in conjunction with Mr. Hinxman, of Durnford House, but being absent, unavoidably, his place was supplied by Mr. Higgs, of Southampton. The Silver Cup, we suppose, will be given to Mrs. Mills, as the winner of the greatest number of first prizes. *Spanish* fowls were indifferently represented; *Coloured Dorkings* were better, and *White Dorkings* were most excellent. Mrs. Mills exhibits birds in this class which in stoutness are seldom equalled. In *Shanghaes*, or *Cochin-Chinas*, the Bufts and Browns were good and numerous; but there were only three pens of White, and the same number of Black. *Malays* were moderate; *Game* but little better; and all the *Hamburgh* classes were below an average. The *Polands* were few, but some good birds were among them. In the *Cross-breeds*, the

chickens (Mr. Fookes fully realize what we have advocated as the result of a union between the *Shanghae* and *Dorking*—the breasts were largely developed. The *Bantams* were all indifferent. The *Geese* most excellent; those which took the first prize weighed 21 lbs. each, and those to which the second was awarded weighed 19 lbs. *Ducks* of all the classes were good, and the *Turkeys* were still more superior. In the class for any distinct variety, the *White Polands* of Mrs. Assheton Smith were very superior, and in admirable condition. In Class 51, the *Crow* fowls, we think, are only bad black Game fowls, but Miss Baulhurst's *Silk Fowls* were of the best we ever saw.

The following is a list of the Prizes :

SPANISH.—*Class 1.*—Exceeding one-year-old. 6. First prize, Mr. T. Pain, Salisbury. 2. Second prize, Mr. James Crane, jun., Tolpuddle, Dorset. Age, two years.

SPANISH.—*Class 2.*—Chickens of 1853. 17. First prize, Mr. P. P. Cother, Salisbury. Cockerel hatched May 20, 1853; pullets, June 20, 16. Second prize, Mr. Clark, Hartley Row.

DORKING (COLOURED).—*Class 3.*—Exceeding one-year-old. 23. First prize, Mrs. Finch Noyes, Laverstock. 26. Second prize, Mr. Jos. Symonds, Gorwell, near Dorchester. Age, one year six months.

DORKING (COLOURED).—*Class 4.*—Chickens of 1853. 32. First prize, Mrs. Finch Noyes, Salisbury. 31. Second prize, Mr. R. Genge, Waterson, near Dorchester.

DORKING (WHITE).—*Class 5.*—Exceeding one-year-old. 46. First prize, Mrs. Mills, Bisterne. 47. Second prize, ditto.

DORKING (WHITE).—*Class 6.*—Chickens of 1853. 52. First prize, Mrs. Besant, Milborne St. Andrews, Dorset. Age, seven months. 51. Second prize, Mr. W. Fookes.

COCHIN-CHINA (CINNAMON AND BUFF).—*Class 7.*—Exceeding one-year-old. 56. First prize, Mrs. James Crane, jun., Tolpuddle, Dorset. 54. Second prize, Mr. F. T. Kelsey, Lavington House, Devizes.

COCHIN-CHINA (CINNAMON AND BUFF).—*Class 8.*—Chickens of 1853. 64. First prize, Mr. W. Flight, Winchester. Age, seven months. 65. Second prize, Mr. H. Fooks, Whitechurch, Blandford. Age, cock, seven months; pullets, nine ditto.

COCHIN-CHINA (BROWN AND PARTRIDGE FEATHERED).—*Class 9.*—Exceeding one-year-old. 81. Second prize, Mr. Woodcock, Fugglestone.

COCHIN-CHINA (BROWN AND PARTRIDGE FEATHERED).—*Class 10.*—Chickens of 1853. 91. First prize, Mr. Wm. Cave, Hartley Row, Hants. Age, seven months. 85. Second prize, Mr. Edwards, Lyndhurst Station. Age, nine months.

COCHIN-CHINA (WHITE).—*Class 11.*—Exceeding one-year-old. 93. Second prize, Mr. Flight, Winchester.

COCHIN-CHINA (WHITE).—*Class 12.*—Chickens of 1853. 94. First prize, Mr. Flight, Winchester. 95. Second prize, Mr. T. Lyne, Malmesbury.

COCHIN-CHINA (BLACK).—*Class 13.*—Birds exceeding one-year-old. 96. Second prize, Mrs. Mills, Bisterne.

COCHIN-CHINA (BLACK).—*Class 14.*—Chickens of 1853. 97. First prize, Mr. Flight, Winchester. 98. Mr. Lyne, Malmesbury.

MALAY.—*Class 15.*—Birds exceeding one-year-old. 102. First prize, Mr. Woodcock, Wilton. 103. Second prize, Mr. C. Coles, Fareham.

MALAY.—*Class 16.*—Chickens of 1853. 105. First prize, Mr. Dawkins, Salisbury. 104. Second prize, Miss Lewis, Martyr Worthy, Winchester. Age, seven months.

GAME FOWL (WHITE, PILES, DUCKWINGS, AND GREYS).—*Class 17.* Birds exceeding one-year-old. 111. First prize, Mr. Mundy, Winchester. (Duckwing.) 113. First prize, Mr. Blake, Castle-street, Salisbury. 108. Mr. Thos. Hall, Newport, Isle of White. (Duckwing.)

GAME FOWL (WHITE, PILES, DUCKWINGS, AND GREYS).—*Class 18.* Chickens of 1853. 118. Second prize, Mr. Mundy, Winchester. (Duckwing.) Age, nine months.

GAME FOWL (BLACK-BREASTED AND OTHER REDS).—*Class 19.*—Exceeding one-year-old. 121. Second prize, Mr. Thomas Hale, Newport, Isle of Wight.

GAME FOWL (BLACK-BREASTED AND OTHER REDS).—*Class 20.*—Chickens of 1853. 125. First prize, Mr. T. Hale, Newport, Isle of Wight. Red. Second prize, Mr. J. Stratton, Bodenham. Age, Cock, nine months; Pullets, seven ditto.

GOLDEN-PENCILLED HAMBURGH.—*Class 21.*—Exceeding one-year-old. 128. First prize, Mr. T. P. Mew, Cowes, Isle of Wight. 127. Second prize, Mr. Robert Fookes, Milton Abbas, Blandford. Age, twenty-one months.

GOLDEN-PENCILLED HAMBURGH.—*Class 22.*—Chickens of 1853. 131. Second prize, Mr. R. Fookes, Milton Abbas. Age, six months.

GOLDEN-SPANGLED HAMBURGH.—*Class 23.*—Exceeding one-year-old. 134. First prize, Mr. T. P. Edwards, Lyndhurst. 132. Second prize, Mr. Genge, Waterson, Dorset.

SILVER-PENCILLED HAMBURGH.—*Class 25.*—Exceeding one-year-old. 138. First prize, Mr. N. Antill, Portsea. 142. Second prize, Mr. Chambers, Portsmouth.

SILVER-PENCILLED HAMBURGH.—*Class 26.*—Chickens of 1853. 144. First prize, Mrs. Mills, Bisterne. 145. Second prize, Mr. T. Mew, Cowes, Isle of Wight.

SILVER-SPANGLED HAMBURGH.—*Class 28.*—Chickens of 1853. 152. First prize, Mrs. Mills, Bisterne. 154. Second prize, Mr. H. Fisher, Blandford.

POLAND FOWL (BLACK, WITH WHITE CRESTS).—*Class 29.*—Exceeding one-year-old. 157. First prize, Mrs. Mills, Bisterne. 158. Second prize, Mr. Edwards, Lyndhurst Station.

POLAND FOWL (BLACK, WITH WHITE CRESTS).—*Class 30.*—Chickens of 1853. 160. First prize, Mrs. Mills, Bisterne. 162. Second prize, Mr. Edwards, Lyndhurst.

POLAND FOWL (GOLDEN).—*Class 32.*—Chickens of 1853. 169. First prize, Mr. Fisher, Blandford. 166. Second prize, Mr. C. Stephenson, Brixton. Age, eight months.

POLAND FOWL (SILVER).—Class 33.—Exceeding one-year-old. 171. First prize, Mr. Parkins Jones, Fulham.

POLAND FOWL (SILVER).—Class 34.—Chickens of 1853. 172. First prize, Mrs. Assheton Smith, Tidworth. 173. Second prize, Mr. Edwards, Lyndhurst.

CROSS BETWEEN ANY BREEDS.—Class 35.—Birds exceeding one-year-old. 175. First prize, Mr. Attwater, Cheltenham. (Dorking and Malay.) 174. Second prize, Mr. Fooks, Tarrant Monckton. (White Dorking and White Cochin.)

CROSS BETWEEN ANY BREEDS.—Class 36.—Chickens of 1853. 188. First prize, Mr. Attwater, Cheltenham. (Dorking and Malay.) Age, seven months. 183. Second prize, Mr. Fooks, Whitechurch, Dorset. (Cochin and Dorking.) Age, six months.

BANTAMS (GOLD-LACED).—Class 37.—199. First prize, Mr. J. Crane, Jun., Tolydale, Dorset. 198. Second prize, Mr. J. J. Fox, Devizes.

BANTAMS (SILVER-LACED).—Class 38.—201. First prize, Mr. Cateels Cooper, Guildford.

BANTAMS (WHITE).—Class 39.—204. First prize, Mr. J. P. Mew, Cowes, Isle of Wight. 206. Second prize, Mrs. Assheton Smith, Tidworth House.

BANTAMS (BLACK).—Class 40.—214. First prize, Mr. J. Fox, Devizes.

BANTAMS (ANY OTHER VARIETY).—Class 41.—220. Second prize, Mr. W. Symonds, Milborne St. Andrew. (Silk.)

GRESE.—Class 42.—231. First prize, Mrs. Pinnegar, Coombe. 224. Second prize, Mr. Edwards, Lyndhurst. (Whole class commended.)

DUCKS (WHITE AYLESBURY).—Class 43.—236. First prize, Mr. Edwards, Lyndhurst. 235. Second prize, Mr. W. Fooks, Tarrant Monckton. Age, nine months. (Whole class commended.)

DUCKS (ROUEN).—Class 44.—242. First prize, Mr. H. Fookes, Whitechurch. 246. Second prize, Mr. John Wickham, Sutton Scotney.

DUCKS (ANY OTHER VARIETY).—Class 45.—248. First prize, Lady M. Macdonald, Liphook, Hants. (Buenos Ayres.)

TURKEYS.—Class 46.—Birds exceeding one-year old. 262. First prize, Mr. I. Waters, Boscombe. 264. Second prize, Mr. C. Smith, Durnford. (Whole class commended.)

TURKEYS.—Class 47.—Birds hatched in 1853. 268. First prize, Mrs. Attwater, South Newton. (Copper-colour.) 272. Second prize, Mr. Symonds, Gorwell. (Bronze.) (Whole class commended.)

DISTINCT VARIETIES.—Class 50.—280. First prize, Mrs. Assheton Smith. (White Polands.) 277. Second prize, Dr. Burney, Gosport. (Ptarmigans.)

DISTINCT VARIETY—CHICKENS.—Class 51.—287. First prize, Mr. Cave, Hartley Row. (Bramah Pouter.) Age, five months. 289. Second prize, Miss Bathurst. (Silk Fowls.)

HARDY BORDER PLANTS.

(Continued from page 268.)

ACONITUM PANICULATUM.

PANICLED WOLFSEANE OR MONKSHOOD.

This is a very desirable kind, having flowers large, and of a pale blue colour. It is said to be a native of France, and introduced to this country in the year 1815. Its roots are tuberous, supported by a large mass of fibres. It is readily increased by division in the spring months, when it first puts up its leaves. The roots may remain in the same spots for many years without injury, or becoming too wide and straggly. Its stems rise, according to the soil and situation, from three to five-and-a-half feet in height. They are much branched upwards, the branches being somewhat twisted, and panicles straggling. The upper part of the flower, or helmet, is conical, or half-circular, and the spur short, thick, and a little spiral. The leaves are deeply cut, or lobed; the segments saw-toothed, and curved upwards at the points.

There is a great similarity in the growth of this species and of the *variegatum*, both in the shape and cut of the leaves, the manner of branching stems, and the form of its expanded blossoms.

It is a very ornamental plant, but, of course, from its height, it should form a bunch in the back or centre row in the borders or beds. It flowers from the end of June to the end of August. T. W.

OUR CONTEMPORARIES.

THE FAMILY FRIEND.—Most unreservedly and strongly do we recommend this little monthly periodical to our readers. Its very varied contents are full of amusement as well as instruction. The illustrations, also, are excellent. As somewhat relative to our own subjects, we quote from it the following, on Salads.

“*Salad.*—The herbs and vegetables for a salad cannot be too freshly gathered. They should be carefully cleared from

insects and washed with scrupulous nicety; they are better when not prepared until near the time of sending them to table, and should not be sauced until the instant before they are served. Tender lettuces, of which the outer leaves should be stripped away, mustard and cress, young radishes, and occasionally small green onions, (when the taste of the party is in favour of these last), are the usual ingredients of summer salads. Half-grown cucumbers sliced thin, and mixed with them, are a favourite addition with many persons. In England it is customary to cut the lettuces extremely fine; the French, who object to the *flavour of the knife*, which they fancy this mode imparts, break them small instead. Young celery alone, sliced and dressed with a rich salad-mixture, is excellent; it is still in some families served thus always with roast fowls. Beet-root, baked or boiled, blanched endive, small salad-herbs which are easily raised at any time of the year, celery, and hardy lettuces, with any ready-dressed vegetable, will supply salads through the winter. In *summer salads* the mixture must not be poured upon the lettuce or vegetables used in the salad, but be left at the bottom to be stirred up when wanted, as thus preserving the crispness of the lettuce. In *winter salads*, however, the reverse of this proceeding must be adopted, as thus: the salad of endive, celery, beet, and other roots being cut ready for dressing, then pour the mixture upon the ingredients, and stir them well up, so that every portion may receive its benefit. In doing this, it should likewise be recollected that the spoon and fork should always be of wood, and of sufficient size to stir up the vegetables in large quantities.

“*Salad dressing.*—For a salad of moderate size, pound very smoothly the yolks of two hard boiled eggs with a small tea-spoonful of unmade mustard, half as much sugar in fine powder, and a salt-spoonful of salt. Mix gradually with these a small cup of cream, or the same quantity of very pure oil, and two table-spoonfuls of vinegar. More salt and acid can be added at pleasure; but the latter usually predominates too much in English salads. A few drops of Cayenne vinegar will improve this receipt. Hard yolks of egg, two; unmade mustard, one small tea-spoonful; sugar, half as much; salt, one salt-spoonful; cream or oil, small cupful; vinegar, two table-spoonfuls. To some tastes a tea-spoonful or more of eschalot vinegar would be an acceptable addition to this sauce, which may be otherwise varied in numberless ways. Cucumber-vinegar may be substituted for other, and small quantities of soy, caviare, essence of anchovies, or catsup may in turn be used to flavour the compound. The salad bowl, too, may be rubbed with a cut clove of garlic, to give the whole composition a very slight flavour of it. The eggs should be boiled for fifteen minutes, and allowed to become quite cold always before they are pounded, or the mixture will not be smooth; if it should curdle, which it will sometimes do, if not carefully made, add to it the yolk of a very fresh unboiled egg. As we have before had occasion to remark, garlic, when very sparingly and judiciously used, imparts a remarkably fine savour to a sauce or gravy, and neither a strong nor a coarse one, as it does when used in larger quantities. The veriest morsel (or, as the French call it, a mere *soupeon*) of the root is sufficient to give this agreeable piquancy; but unless the proportion be extremely small, the effect will be quite different. The Italians dress their salads upon a round of delicately toasted bread, which is rubbed with garlic, saturated with oil, and sprinkled with cayenne, before it is laid into the bowl: they also eat the bread thus prepared, but with less of oil, and untoasted, often before their meals, as a digester.

“*French Salad dressing.*—Stir a salt-spoonful of salt and half as much pepper into a large spoonful of oil, and when the salt is dissolved, mix with them four additional spoonfuls of oil, and pour the whole over the salad; let it be well turned, and then add a couple of spoonfuls of vinegar; mix the whole thoroughly and serve it without delay. The salad should not be dressed in this way until the instant before it is wanted for table; the proportions of salt and pepper can be increased at pleasure, and common, or cucumber-vinegar may be substituted for the tarragon, which, however, is more frequently used in France than any other.

“*Another Salad dressing.*—Boil two eggs ten minutes, and put them into cold water, to harden and cool; then take out

the yolks, and rub them through a coarse sieve into a basin; add two table-spoonfuls of olive-oil, a tea-spoonful of salt, the same quantity of mustard, half the quantity of ground black pepper, a tea-spoonful of soy or essence of anchovies, and two table-spoonfuls of vinegar; incorporate the whole, and pour this sauce down the side of the salad-bowl. The whites of the eggs will serve to garnish the salad.

"Summer Salad.—Wash very clean one or two heads of fine lettuce, divide it, let it lie some time in cold water; drain and dry it in a napkin, and cut it small before serving. Mustard and cresses, sorrel and onions, may be added.

"Winter Salad.—Wash very clean one or two heads of endive, some heads of celery, some mustard and cresses; cut them all small, add a little shredded red cabbage, some slices of boiled beet-root, an onion, if the flavour is not disliked; mix them together with salad sauce. In spring, add radishes, and also garnish the dish with them.

"Vegetable Salads made of roots which have been boiled, also make good winter salads, amongst which *potato* and *beet-root salads* are perhaps the best. Cut the roots into thin slices, season them with pepper and salt, and pour over them the salad mixture, to which may be added, if the flavour be not disapproved, a few slices of raw onion.

"French Salad.—Chop three anchovies, a shalot, and some parsley, small, put them into a bowl with two table-spoonfuls of vinegar, one of oil, a little mustard, and salt. When well mixed, add by degrees some cold roast or boiled meat in very thin slices; put in a few at a time, not exceeding two or three inches long. Shake them in the seasoning, and then put more; cover the bowl close, and let the salad be prepared three hours before it is to be eaten.

"Italian Salad is made by picking the white portion of a cold fowl from the bones in small flakes, piling it in the centre of a dish, and pouring a salad mixture over, enriched with cream; make a wall around with salad of any kind, laying the whites of eggs, cut into rings, on the top in a chain.

"Spanish Salad.—Take whatever salad can be got, wash it in many waters, rinse it in a small net, or in napkins, till nearly dry, chop up onions and tarragon, take a bowl, put in equal quantities of vinegar and water, a teaspoonful of pepper and salt, and four times as much oil as vinegar and water: mix the same well together; take care never to put the lettuce into the sauce till the moment the salad is wanted, or it loses all its crispness and becomes sodden.

For Vinaigrette.—Take any kind of cold meat, chop it finely, and lay it in a dish; chop the whites of the eggs employed for the salad very finely with small onions; add any kind of herb, and pickled cucumbers, all chopped finely: make a garnish round the meat, serve it with salad mixture, but do not stir it together, as it would spoil the appearance of the dish, which looks very pretty with the eggs and herbs in a ring.

"Chicken Salad.—Boil a chicken that weighs not more than a pound and a half. When very tender, take it up, cut it in small strips; then take six or seven fine white heads of celery, scrape and wash it; cut the white part small, in pieces about three quarters of an inch long, mix it with the meat of the fowl, and just before the salad is sent in, pour a dressing made in the following way over it. Boil four eggs hard; rub their yolks to a smooth paste with two table-spoonfuls of olive oil; two tea-spoonfuls of made mustard; one tea-spoonful of salt; and one tea-cupful of strong vinegar. Place the delicate leaves of the celery round the edges of the dish. White-heart lettuce may be used instead of celery. Any other salad dressing may be used, if preferred."

TO CORRESPONDENTS.

WILLIAM ADAMS (C).—Both your very kind enclosures have been received, and applied as nearly as possible as you directed. The Author's of "My Flowers" will explain more.

DISEASED GERANE (A. L. C.).—The leaves of your *Eschmanthus* and *Columnea* are diseased; the inner substance of the leaf appears to be destroyed. You wish to know how to restore them to health. The diseased leaves cannot be restored, and, therefore, they may as well all be cut off at once, and if the shoots are thereby left quite naked it will be advisable to shorten them in also freely. The plants should have fresh compost to grow in, and a brisk heat to start into fresh growth. Do this well, and disease will disappear. Did you ever observe a little insect, or grub, in the interior of your leaves? The disease is very likely caused by such a grub. Celery leaves are often destroyed in apparently

a similar manner to the leaves of your *Columnea*, &c.; and the mischief is certainly done to the Celery by a little mining grub.

TRAILING VERBENAS (Ferns).—There are very few of our modern Verbenas that have the trailing habit of *Verbena melindris*. The only ones are varieties of that species—namely, *V. melindris major* and *V. melindris alba*. There is an old sort named *Hendersonii* that creeps, and it has dark purplish-crimson flowers. *Ormsby Beauty*, also, has a dwarf habit, and is a pleasing light blue; but it is none of the *melindris* breed.

CHRYSANTHEMUMS (Homo).—You ask more than we can tell you. We should suppose there are no Chrysanthemums that are hardly enough to blow out-of-doors as far north as Lancashire. Have you ever seen any? The following is a list of the best now grown, arranged in the colours you mention:—*Rose*—Amazon (Salter), with orange border; Fortune, ditto; Agenor (Salter), Barhette. *White*—Diamant de Versailles, Ermine, Fleur de Marie, Gem de Versailles, Lady Talford. *Purple*—Leon Laquay, Armand Tossier—these are very few of this colour. *Bright Scarlet*—The nearest approach to this colour is *Atrorubens*, raised by Boulanger, of Paris. *Mound Etna* is a red. There is not a bright scarlet in existence. *Yellow*—L'ingot d'Or, Annie Salter, Cloth of Gold, Nandee. *Orange*—Pondre d'Or, La Reine d'Or, Plutus, Gluck, Temple of Solomon. *Dark*—Rantonette, Comte de Ranton, Madame Poggi, Phidias. The price of the above would be, on an average, about 12s. the dozen. We cannot recommend dealers. Any respectable nurseryman would supply you. Your other questions will be answered shortly.

ROCK-WORK IN FERNERY (D. E.).—You are erecting a house for Ferns, and intend planting them out against the walls, in a kind of rock-work, and wish to know the material to be had. If you can get rough sandstone, that would answer well. It might be placed irregularly against your walls, with spaces left to hold soil for the Fern-roots. There is a Fern-house at J. Anderson's, Esq., the Holme, Regent's Park, London, where the Ferns are planted against the walls in a kind of rustic basket, or nest, made with Roman cement. If stones are scarce with you, you might make a similar arrangement, having the largest spaces towards the bottom, and the smaller upwards, to grow in each Ferns of proportionate size. Read Mr. Appleby's papers on Ferns; he describes the height each grows to. In the meantime, we give the list below, agr eable to your request. None of them are expensive, but all require moderate heat:—*Adiantum assimile*, medium size; *A. concinnum*, medium; *A. formosum*, large; *A. trapeziforme*, large; *Acrostichum alaicorne*, large; *Aspidium coriaceum*, large; *Asplenium auritum*, small; *A. ebeneum*, small; *Blechnum intermedium*, small; *B. occidentale*, medium; *Cissaberna hastata*, medium; *Cheilanthes lindigera*, medium; *C. repens*, large; *C. tenera*, small; *Ctenopteris cicutaia*, medium; *C. viviparum*, medium; *Cyrtium falcatum*, large; *Davallia canariense*, medium; *D. pycnata*, large; *Doodia aspera*, small; *Gymnogramma calomelanos*, large; *G. chrysophylla*, medium; *Pteris chinensis*, medium; *P. sagittifolium*, small. In addition to these, you should have all the *Lycopodiums*.

HEN DEAD ON THE NEST (T. S.).—In this case, in which the hen was fed on Indian meal and bran twice a-day, with corn and drier, the death, doubtless, arose from apoplexy, which is not untrifling in fat laying hens. Indian meal and bran both contain a high proportion of fat-forming food, and being largely supplied, no doubt conduce to the attack. A little raw, dry rice could not have had any ill effect, although, if much were given, it might swell to so great a degree as to cause the bird to become crop-bound. Under any circumstances, rice is better given after having been cooked.—W. B. T.

COCK WITH MALFORMED TAIL (A Dorking Fancier).—The occurrence of soft quills filled with blood in the tail of a cock, in the place of well-formed feathers, depends evidently on some irregular action of the parts which form or secrete the feather; and as these are situated deep in the skin it is difficult to suggest a remedy. It would, perhaps, be most advisable to trust to the restoration of the natural action at the next moulting time.—W. B. T.

DISEASED RABBIT.—Can any of our readers give *Acute* information on the following case?—"On examining a rabbit of the Lop-eared breed to-day, I found one ear completely filled with a hard matter resembling scurf; on touching the ear the rabbit screamed out. I then took as much of the hard stuff off as I could, and bathed with warm water; after that I greased the ear well. I took two pieces as large as a man's finger from the ear, which seemed to reach quite to the farthest extremity. Can you tell me the cause of this, and a remedy for same?"

COCOA-NUT (Linda).—The end of the nut, which has the three circular marks or scars, "commonly known as the monkey's face," is the base, or that next the stalk. It is not generally known that these three marks indicate the places through which the three embryos each nut contains would sprout forth if each was completely developed. Two, however, are constantly abortive; and which is the fertile may be ascertained by trying to thrust a pin into each scar. Those two which the pin cannot pierce are those over the undeveloped embryos.

EXCHANGE (W. Nicholas).—We cannot insert such a proposal. When we have seen a specimen of your communications we can decide whether they are suitable.

VINEGAR PLANTS (Raysent).—We cannot undertake such negotiations. You had better advertise.

TAUNTON SHOW (J. E. M.).—We are much obliged; but as the committee did not think it of sufficient interest to our readers to advertise it in our columns, we cannot allow ourselves to shew we differ from them by inserting their prize list.

INSECT ON CINCERARIAS (An Enquirer).—It is the thrips which has attacked them. Dust over the insects frequently with Scotch snuff, and syringe the leaves when the weather permits.

HALL'S GARDEN NETS.—Mr. J. Murchum, Lichfield, wishes to know where these can be obtained.

METEOLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 43.1° and 33.1° respectively. The greatest heat, 60°, occurred on the 19th in 1828; and the lowest cold, 45°, on the 19th in 1838. During the period 93 days were fine, and on 96 rain fell.

BRITISH WILD FLOWERS.

(Continued from page 233.)

ARABIS HIRSUTA: Hairy Wall Cress; Daisy Tower Mustard.

Description.—It is a perennial. Root strong and woody.

Stems several, about a foot high, upright, leafy, clothed with thick-set, spreading, or partly bent-down hairs; branched, and less hairy, at the top. Leaves bluish, variously toothed, more or less rough, with short, bristly, simple or forked, prominent hairs; the root-leaves largest, reversed-egg-shaped, tapering at the base; stem-leaves numerous, stalkless, oblong-egg-shaped. Flowers small. Calyx smooth, purplish. Petals white, moderately spreading. Stigma stalkless. Pods forming very long, close, smooth clusters, erect, slender, smooth; valves with a slight keel half way up, undulated from the alternate projection of the seeds, which are in a single row, not a double one like *Turritis*. This last character, confirmed by a similitude of habit, is admirably chosen by Mr. Brown to define the genus *Arabis*, in contradistinction to *Turritis*, whose much more numerous seeds are disposed in double rows.

Time of flowering.—May.

Places where found.—On old walls, stony or rocky banks, and mountain dry pastures. Not common.

History.—Parkinson calls this the *Erysimum* or "Hairy Hedge Mustard, with uncut leaves," and Ray describes it as *Barbarea muralis*, "Wall Cress, or Tower Mustard, with Daisy leaves." It is the *Turritis hirsuta* of Linnæus, and many other botanists. If grown in a rich soil it not only acquires a much larger size but loses all its hairiness. It is one of the "Scitica Cresses" of the old herbalists, who say that if the roots, or leaves, but especially the roots, are bruised in summer, and made into an ointment with hog's-lard, applied to the part affected with rheumatism, for four hours, and the place afterwards bathed with a little oil, and covered with wool or other warm wrapper, a cure will always be effected. (Smith. Withering. Ray. Parkinson.)

THE January Meeting of the *Entomological Society* was held on Monday, the 2nd inst., at the Society's Rooms, and, notwithstanding the great severity of the weather, was much better attended than could have been anticipated. The Members of the Council had, however, been especially summoned to a meeting previously to the general meeting, to settle the lists of Council and Officers for the ensuing year, to be proposed at the Anniversary Meeting on the fourth Monday in the month; the result of which was, that Messrs. Spence, Curtis, Westwood, and Janson, are proposed to be removed from the Council, and Messrs. Stainton, Dallas, F. Smith, and Edward Shepherd, to be elected in their stead. We are not sorry to perceive, in this arrangement, that the Council are anxious to bring the younger active members of the Society into the Council, re-

moving such as from their length of service may desire to be released from the duties; but we think that the rule which is adopted of striking off such Members as have attended the Council Meeting the fewest number of times has been too rigidly adopted in the case of one of the gentlemen proposed to be removed, as his absence was known to have arisen from his having been abroad for a long period, and his long service and devotion to the science, with his return to this country, ought, in our opinion, to have ensured his retention on the Council, and which, in fact, we hope may still be effected at the Anniversary Meeting. The Council do not propose any alteration in the list of officers for the ensuing year.

Amongst the donations to the Library and Museum, received since the last meeting, were the "Transactions of

the Natural History Society at Vienna;" the "Journal of the Entomological Society of Stettin;" an elaborate Memoir on the anatomy, history, and transformations of the common domestic Black-beetle, or Cock-roach (*Blatta orientalis*) in which the author has endeavoured to investigate the place of its origin, whence it has been so widely distributed over the habitable world; the remarkable nature of its egg-case, &c., is also carefully examined and described.

A number of splendid *Lepidoptera* were presented by Mr. Jones Stevens, of Bogota; and various species of rare British *Microlepidoptera*, by Mr. Vaghan, of Bristol. A note was communicated on the decease of Mr. Whitfield, the African traveller and collector, by whom so many rare animals had been brought to this country. Mr. Samuel Stevens exhibited some specimens of the splendid *Morpho Ganymede* (*Morpho Sulkowskyi*, of Kollar, recently described and figured in the Vienna Transactions), which he had received from Mr. Jones Stevens, of Bogota. One of the specimens had arrived in a bad condition, being saturated with an exudation of grease. Having, however, dipped the Butterfly in camphine, and then powdered it over with magnesia, or pipeclay, the grease is entirely absorbed, and the fly has entirely regained its former brilliancy. Mr. S. Stevens also exhibited some beautiful *Lepidoptera* from Manilla. The Secretary read a note by Mr. Jones Stevens, on the occurrence of many species of minute moths in Bogota, but as they generally came to the lamps at night, they could not be captured and preserved in good condition.

The Secretary also read a note by Mr. R. Fortune, from the *Gardeners' Chronicle*, on the mode of taking honey from bee-hives in China. The Chinese hives consist of a rough box, square or cylindrical, with a moveable top and bottom, which is rarely placed near the ground, as with us, but is raised eight or ten feet high, and generally fixed under the projecting roof of a house or out-building. When it is desired to take a portion of the honey, the hive is gently lifted down, and placed on its side on a table; the moveable top is then taken off, and as much honeycomb as is considered desirable cut out with a knife, made apparently for the purpose, having the handle almost at right angles with the blade; the top is then replaced, and the hive elevated to its former position. The bees had neither been killed by fumes of brimstone, as it is contrary to the Buddhist Creed to take away animal life, nor had they been stupefied with fungus, but they were flying overhead, during the operation, in great numbers, without even stinging the half-naked operator; but they were rendered harmless by the smoke of the dry stems of leaves of a species of *Artemisia*, which grows wild on the Tea-hills, which is cut early in summer, sun-dried, and twisted into bands, and used for this purpose, as well as for driving the Mosquitoes out of the dwellings.

Mr. Westwood stated that a similar plan of taking honey had been adopted by an apiarian neighbour of his at Chiswick, and who, having turned-up the hive to be operated upon, partially stupefied the bees by a few

whiffs of tobacco-smoke; he had himself succeeded in extracting as much comb as was desirable from his hives even without the use of tobacco, by simply turning the hive upside down, and driving the bees into an empty hive, and then cutting out the comb, working slowly and quietly, and brushing off the few bees which remained in the comb with a feather.

Mr. Curtis read a note upon the habits of *Panurgus ursinus*, a curious wild Bee, which he had observed formed its burrows on hard earth at Tunbridge Wells. He had noticed the females occasionally curled up, as if asleep, in the flowers of *Hieracium*; and at other times with their hind-legs laden with pollen. The first portion of a Memoir on the *Chrysomelida* of New Holland, by Mr. Baly, was read, containing the genera *Phyllocharis* and *Lamprolina*; also, descriptions by Mr. Hewitson, of new species of Butterflies from Bogota; and an elaborate Memoir by Dr. Davy, F. R. S., on the Chemical Analysis of the excrement of insects, from which some remarkable results were deduced, with reference to the analogies exhibited with the urinary and excrementitious secretions of birds, serpents, &c.

AFTER two years' experience, we think it right to express our firm conviction that the most valuable domestic Fowl at present known to us is the Shanghai, or Cochin-China.

If any one conversant with poultry as a stock for profit were asked to give what he considered the points of excellence desirable in such fowls, he would reply—"They should be large, quick of growth, hardy, fit for the table at an early age, meaty, abundant layers, especially in winter, good mothers, quiet in their habits, and their feathers valuable for the upholsterer."

Now, in every one of these points do the Shanghai excel. Their feathers are equal to those of the Goose. No fowl known to us is so gentle, or can be kept within a boundary no higher than three feet. Better sitters, or mothers more careful of their chickens, cannot be found; and at the end of a month from their hatching time they will again begin laying with their chickens around them. That they are early fit for the table is told by the facts that cockerels are best cooked when from four to five months old, and pullets when from five to six months old, and that, if tolerably well fed, they will weigh about 1½ pounds for every month of age. As to their hardihood, we have not heard of their suffering anywhere during the late severe weather, though we know of many that endured it with no other shelter during the day than a roofed shed, boarded up on the north and east sides. As layers they are surpassed by none. We have known instances of pullets laying more than 190 eggs without requiring to sit. Pullets when six months old begin laying, and continue doing so throughout the winter.

As to their meatiness, the very great mistake is being assented to by some breeders of this fowl, that there is more of giblets than meat upon them. It is quite true that most of the meat on a cockerel is upon the legs,

but it is not so in the case of pullets, for these have breasts quite as well developed as the usual breed of barn-door fowls. Those who condemn the Shanghae as a bird deficient in producing serviceable flesh, ground that condemnation on the crooked-breasted, crooked-backed, or otherwise imperfect birds that are rejected from the stock. Good, short-legged, compact pullets are too valuable as yet to be killed usually for the table, but we can attest that such birds are as meaty on the breast even as Dorkings, and the flesh is more juicy, but not so close grained.

The sole point of inferiority, then, which can be established against the Shanghae fowl is that its cockerels are deficient in breast meat. Then, to make the breed perfect, let breeders set about selecting birds for stock that are characterised by well-developed breasts. We know of one cock that is breasted like a Dorking, and he will be coupled this season with an imperted hen that has the largest development of breast we ever knew in any bird. The attention of the breeders of Shanghaes has been most successfully directed towards the improvement of colour—let it now be turned to the more important improvement of an increase of flesh upon the breast. We know, from experience, that it is to be effected; and the results of further experiments, we are confident, will be still more effectual. The two brothers, Messrs. R. and C. Colling, achieved far greater changes in the arrangement of meat upon their Short-horns than has to be accomplished upon the Shanghae.

Even whilst we are writing this we have received letters confirmatory of our views. Thus, a first authority, writing to us about the recent challenge exhibition, expressly says that *form*, and not mere size, gave the palm to Captain Snell. His letter is as follows:—

“The town of Honiton, Devonshire, was, on the 28th ult., the scene of far greater excitement than has hitherto agitated the poultry world, and the influx of amateurs from long distances was far beyond all precedent. Though situate twelve miles from the nearest railway station, Liverpool, Manchester, Shrewsbury, Birmingham, and intermediate places, sent incredible numbers of the poultry fancy, while not a trifling addition of amateurs reached Honiton from the metropolis.

“This was occasioned from the news being carried, with wild-fire rapidity, that the challenge of Captain Snell, of St. Swithin's Lane, London, to all Cochin-China breeders in Devon and Cornwall, to produce the equals of those that gained first prizes in London, Southampton, and various other places, had been accepted by Mr. W. L. Channing, of Heavitree, Exeter, and that the event was to take place at the Honiton Exhibition of Poultry.

“Each pen of birds had its confident supporters, who somewhat liberally espoused their individual opinions by making it the subject of a ‘betting speculation;’ and, no doubt, considerable sums changed hands in consequence. Another notoriety of this affair arose, too, from the lengthy correspondence that had previously taken place, in the public newspapers of Devonshire, between their respective owners. To prevent the possibility of any unfairness, the committee had (with the sanction of the owners) placed the rival favourites intermixed among thirty other pens in the same class, and secured the services, as judge, of Mr. Edward Hewitt, of Eden Cottage, Birmingham, to officiate on this unusually important occasion—so that not the slightest possible clue might offer itself, either as to the ownership of the ‘favourites,’ or their individuality. These arrangements complete, the anxiety to ascertain the result

was unceasing; and every stratagem was called into play to get early information of the successful ones; and not till the public admission was it known that another chaplet was added to the existing laurels of Captain Snell, though the most diverse statements on the affair had been ‘flying about’ for hours previously to the judge entering on his duties. It is very doubtful whether two so perfect pens ever before contested publicly for the mastery, and certain it is that time will long pursue its onward course before such rivals again enter the lists. One marked difference was at once apparent—that the defeated fowls, in regard to size, had the superiority; not so, however, in respect of formation and colour—Captain Snell's being a perfect self-coloured light butt; his rival's, on the other hand, being what is termed ‘mealy,’ or ‘grizzled,’ more especially on the wing coverts; neither could they boast of the perfection of shape that marked the winning pullets—one, more especially. The visitors, generally, made the space opposite ‘the favourites’ the trysting place during their stay; while not a few, negligent of the excessive fall of snow, found it impossible to reach the trains in due time, and were, therefore, compelled to pay ‘a visit to mine host,’ to discuss over their wine the events of the closing day.”

Then, as to the table merits of the Shanghae, J. B., whose address we have, writes thus:—

“In publishing my ‘Poultry-yard Report,’ in your number of the 29th December, a mistake has been made. Instead of ‘Mr. Baily, of Mount Street, says flesh-coloured legs are inadmissible,’ it should be, ‘flesh-coloured legs are *admissible*’—just the opposite. I have lately had several Cochin chickens of four to six months old at table; the pullets were round and compact birds, but the cockerels rather leggy. The colour of some of them rather yellow before cooked, but of others not to be complained of. They were, however, *my worst-coloured fowls* that I killed. I am persuaded that the colour of my best light-feathered Cochins (none of which I have killed) would be unexceptionable in colour when killed, particularly those with pink-white legs. As to the eating of those already had to table, they were very superior to the common run of fowls—particularly tender, juicy, and well-flavoured. This opinion has been expressed by several, who should be judges, who have partaken of them at my table. I am persuaded that this breed will stand their ground as a very useful, if not the most useful, fowl. A *first cross* with the Dorking I can well conceive to be a first-rate table fowl.”

On the 9th, 10th, and 11th, took place sales by auction of drafts from three of the best Poultry Yards of England—Mr. Sturgeon's, Mrs. Herbert's, and Mr. Punchard's. We know that it has been an opinion prevailing recently that the taste for Shanghaes is declining. This opinion we felt convinced was grounded upon the fact, that at various recent sales (Mr. Stevens has had thirty-six in about as many weeks) the prices have been low. On the other hand, we saw in this no other proof than that the public judgment had improved, for the low prices were those given for indifferent birds. The results of these three sales testify that we were correct, for all the good birds realized good prices.

At Mr. Sturgeon's sale, the 100 lots sold for £275 17s. 6d. At his sale, in November, 1852, the highest sum given for one bird was £12 10s. for a cockerel, but this year, £13 10s. was given for Lot 39, “Rich buff cockerel, well-feathered, and of good weight;” another cockerel, Lot 16, sold for £10 15s., and two of the hens, Lot 42, “sister to the ‘Queen,’” sold for £7 7s.; and Lot 42, for £9 15s. A hen of 1851, winner of the

Cheltenham Cup, realised £10 10s. Of the *White Shanghaes*, the highest sum given for a cockerel was £4 5s., and the highest for a pullet, £1 15s.

Mrs. Herbert's fowls were sold on the 10th. Her *Buff* birds were very bad indeed, and her *Blacks* very little better; not one of the cockerels being without red feathers. Her *White Shanghaes*, for which she has been so justly celebrated, are not so stout as those of last year's sale. Seventy birds of these Whites were sold for £110. The highest price was £10 10s., and that was for the cockerel which took the first prize at Birmingham in 1853. The three pullets which accompanied him on that occasion sold for five guineas each.

Mr. Punchard's Shanghae fowls, all buff and cinnamon, were sold on the 11th. They were not so good as those drafted from his yard last year, being smaller and deficient in substance. The cockerels were better than the pullets. There were 160 Lots, and they sold for £176. The highest price given for a cockerel was £7 10s. for Lot 49, he having taken the second prize at Norwich, and been highly commended, at Birmingham. The largest sum given for a pullet was £4 6s. for Lot 63.

THE WINTER: ITS PROBABLE EFFECTS ON VEGETABLES, &c.

If the weather has been as severe in other parts of Britain as it has been in Cheshire, I make no doubt that a great outcry will prevail about the losses in our kitchen-gardens. I am not aware (speaking of the present moment, January 2.) that I ever saw stronger signs of extremely severe weather for a few days, for the thermometer now, whilst I write, six o'clock, p.m., is down to 6°, which is what we gardeners consider rather a strong case. But the accompaniments are remarkable; the wind has been vacillating in a singular way, although, to observe the extremely quiescent state of the air, one might materially imagine that not a disturbing cause existed. It rather reminds one of the accounts we have read of the conditions of atmosphere in the Polar regions, for although such an extreme depression of temperature exists, the air is bearable: I have known many a day in the beginning of March less so, when we have had a frost only some 10° or 12°, but accompanied by a cutting north-easter. Verily these winds are the greatest refrigerators, taking away not only warmth, but robbing all vegetable bodies of that moisture which not only promotes their succulence, but constitutes, as it were, their life-blood and energy.

I well remember the great frost of 1813—14^(?), when the Thames was frozen, and a fair held on it. That very year I had left my school, which was on the banks of the Thames, opposite to the old Church at Putney; and having a few holidays before I was compelled to put my shoulder to the wheel, I was daily on the Thames with my school-fellows, and many dangers we narrowly escaped in crossing to Fulham on the icebergs which floated abundantly on the Richmond side of the bridge, whilst, strange to say, on the London side all was smooth ice, and, indeed, there the fair was held, with all its paraphernalia of printing-presses, booths, roundabouts, swings, &c.

But to my tale; I do not think that the present position of affairs greatly resembles it. A south-east wind greatly prevailing, a creamy condition of air, with huge rolls of mist in the evening, like the lace in folds round a lady's cap, rolling stealthily over the meadows,

at four o'clock, p.m., at about six feet above the ground level.

I should not depart so wide of the Cabbage and Lettuce question, but to furnish notes for comparison with those of distant friends, for, doubtless, many a one will be dreading the upshot, as we do in this quarter. To give a slight detail of recent temperatures, I must observe, that the frost here may be said to have set in at precisely the same period as on that former memorable occasion, viz., the day after Christmas-day, which, if my memory does not prove treacherous, was the exact period.

On Monday evening, the 26th, a slight frost occurred; in the night, on Tuesday, a good deal of snow fell; on Wednesday frost continued; and on Thursday morning, at seven, a.m., thermometer down to 6° or 7°; and on that same evening, rain, with a temperature ranging from 30° to 40°. On Friday, froze again; continued on Saturday. On Sunday afternoon, and through part of the night, a right old English snow, on Monday morning averaging six inches in depth, when we had to put our ice plough into requisition, for besoms were helpless, you might as well have had a lady's fan; and now, as before observed, the thermometer about 6°, with such a hoary starving look as would almost startle a veteran of the Siberian deserts.

Further I cannot report now; therefore let us see about its application.

One of the first families of vegetables which suffers is the Brocoli, and these are rather difficult to replace. Little can be done for these after suffering from the effects of severe weather; those that are half-killed must, of course, fall off in an immature state, and such being generally half-decayed in the stem, produce very lean and small heads. With regard to these things, every pains should be taken to get the hand-glass Cauliflowers forward, as if the destruction amongst spring Brocoli is very great there will be an unusual desire for these betimes. Plants, well-established in pots in the autumn, very sturdy, and preserved hitherto in frames, or pots, may be repotted, and placed in the front of some house in the course of January; these, with the use of liquid-manure, will be strong indeed by the end of February, when they may be got out under hand-glasses in rich soil, and every attention being paid them, nice Cauliflowers may be cut in the beginning of May. Lettuces will, doubtless, be heavy sufferers, especially those which were very strong plants in October, and to provide against such a mischance, sowings should be made immediately in boxes, or pans, and these introduced immediately to heat.

As soon as the young plants can be handled, a frame possessing a bottom heat of about 60°, should be appropriated to them, and they should be pricked out in rich soil, very close to the glass, and receive covering in severe weather. Such may be pricked out by the end of the month, and will be stiff little plants by the third week in February, when they must be hardened off, and planted out in prepared soil, in very warm situations, on elevated beds, and by receiving every attention, with an occasional liquid-manuring during dry weather in March and April, good Lettuces may be produced by the end of the latter month and all through May. Cabbage plants, too, are apt to suffer much in such winters, and even those of the dwarf, hearting kinds may be sown in heat, and transplanted after the manner of the other things. Those planted out in autumn should have examination during the first dry weather at the end of January or first week in February, they are apt to become loose in the soil. Such should be fastened, and have the soil drawn close to their necks; all blanks, too, should be made good, and towards the middle of March they will begin to benefit by a liberal application of liquid-manure during dry periods.

A close examination of all store roots should take place as soon as possible, and these should be all turned over and picked. Beets will have sprouted, and Parsnips, Carrots, &c., should have all sprouts and roots rubbed away. It is a capital plan to spread them in the sun and wind for several hours to kill the young fibres, and then to store them again. *Kidney*, or other early Potatoes, in early frames, may be placed in simple layers in boxes, first putting a layer of leaf-soil in the bottom, and sticking their ends in it; they may then be introduced to heat to sprout, but it will be well to cover them over their crowns with very fine manurial matter, which will cause them to produce strong sprouts. Such may be planted with fine sprouts three inches in length, in prepared beds, in the middle of February, and will, with proper attention, probably be found earlier than those planted at once in hotbeds in the end of December.

I may first mention, in addition to what I had previously stated with regard to the weather, that the thermometer, whilst I finish these observations, January 3, six o'clock, P.M., may be quoted about 3°; but as I do not place extreme reliance on my glass, it is not improbable that we may hear of its being below zero in some places.

It is not improbable that this weather may be followed by cutting winds, if so, it is fearful to contemplate the havoc amongst vegetables, tender trees, &c. This weather will also put some of our so-called hardy new shrubs and trees to the test, and will tend to purge some of our trade catalogues of over-glowing descriptions.

R. ERRINGTON.

PRACTICAL PRUNING.

WHEN a child is born high up in the world, I mean, up among the hills, the boy or girl is so far apart from other boys or girls, that a great deal is to be learned from the natural bent of the mind and body; add to this, that when the grown-up people gather together, as to a wedding, or a dance, or at sheep-shearing, or at "marking the lambs," or on any other common occasion, the boys and girls are put out of the way lest they should be troublesome; besides, these high born little ones are never allowed little high chairs to sit at table, they must take their porridge elsewhere, as it happens; so, as I have just hinted, they have no chance to learn much from doing what they see others do, for they do not see them at their doings. I believe, that if a dull child, say a boy, were left on an island where there was no one but himself, but where there were plenty of birds and animals, that he would learn two things, at least, that are prized in civilized life; he would learn to like flowers, and he would learn to dance from what he saw around him. No great credit thus for highlanders being such good natural dancers, yet they find it very difficult afterwards to learn it by rule and note; but when they get over the first three steps, the "one, two, three, and a hop," all the difficulty is over.

It is just the same in pruning. The man who has been accustomed to cut and prune after his own natural fashion, or as if he came to this world for no other purpose, will find it a hard and tedious process to follow and imitate the first three steps of the scientific pruner, even though the said pruner is guided as much by circumstances as by scientific rules; but no sooner does he master the first three fundamental rules for pruning than the difficulty is over. We must not suppose, however, that the thing is either easy to learn, or that every one can be a thorough master of it; like every thing else, there will always be better pruners than others, teach or practice as we may. To be a good general

pruner requires a long course of practice, because it is from that alone that we can learn the vast variety there is in the nature of so many kind of plants and trees. A forester may prune his Oaks to perfection itself, and yet cut a sorry figure against a Peach wall; and a smock-frock customer, in Kent, may prune a filbert bush better than my lord's gardener. So on to the end of the chapter.

Here we have certain kinds of trees to fill up the boundary line of a confined garden for a screen, such as Poplars, Maples, Thorns, Oaks, Horse Chesnuts, Spruce and Silver Firs, Scotch Pine, Larch, and such trees, and we must not allow them to spread out their limbs over our neighbour's garden, or suffer them to trespass on our own more choice trees and shrubs in front of them along the border. We have thus a definite object to prune for, as much so as he who prunes for a crop of fruit; and if we take heed as to how we start, our trees are just as easily managed, and more so than the Peach or Apricot against the wall. All depends on the style of pruning for the first few years. I once cut in a shoot of a *Pinus excelsa* in the month of May, and it bled as fast as the drops could run, and the sap was as thin and clear as spirits of turpentine. I never saw any tree bleed so fast before or since. I repeated the experiment two seasons after that, and at the same time, when the sap flowed as before. I never knew a Spruce or a Silver Fir to drop the sap after a cut at any season, but if they are pruned late in the spring, they, and the Larch, as well as many other conifers, will ooze out a kind of resin in the form of gum; therefore I should not like to make free with any of the tribe, by way of pruning, from the end of March till after Midsummer, and I would not hesitate to cut them at any other season, so that the whole of the boundary trees under consideration may be pruned any time in the winter; but from the middle of June to the middle of July is the best time in the whole year to prune all forest trees whatsoever; the reason for that is, first, that none of them bleed at that season, the growth being then so rapid as to suck up all their sap faster than it comes, leaving none of it to run over; and secondly, that at that season growth is so vigorous, extending the seat of life outwards, that new wood is soon formed over small wounds, and round the sides of larger wounds; whereas, all wounds, or cuts, made from the end of October to the end of May, must necessarily stand fully exposed to all weathers till the Midsummer following. The worst of it is that few people can spare time for summer pruning.

The Spruce, Silver Fir, and Larch, and most conifers, seldom require any pruning in a boundary line, or anywhere in a garden, until they are old and full grown, and then all they require is to thin out the spray on the chief limbs, if the parts get too crowded, or, as is too often the case, if they were planted too close at first, and are now hurting each other, or some valuable shrubs near them, when the tops of the branches, which overrun the space between them and the shrubs, may be shortened back without any harm. So, too, if the Fir branches hang over the next door neighbour's garden, for, be it remembered, I am now contemplating one of the evils of a house semi-detached; builders will put up houses in pairs, and divide them and the garden across the middle, and if you plant trees along the boundary of No. 1, they will spread their branches over No. 2, and so will those of No. 2 in the other directions; thus the occupiers turn colours, the one looks black and the other looks blue, and soon they are as much divided as the houses and gardens they severally occupy; therefore, if only for the looks of the thing, it is surely worth while to learn to prune boundary trees before all other trees.

According to my tale, almost all trees can be so pruned as to grow something in the way of trees trained against

walls, that is, two-sided back boughs are stopped, from time to time, to prevent them spreading over to the other side, and front boughs the same, to keep them from trespassing on our own more choice things in front of them, and this stopping on two sides will force much of the growth right and left, and that will fill up the boundary-line much sooner and better than letting the trees grow in a more natural way. The only difficulty lies in this, the chance of having our trees look so much like a hedge, and that difficultly no pen can remove, but nothing in the world is more easy for the knife. A good pruner can give any form or turn to a tree, and still it will look as if it took that particular form naturally, and that is the right test for a good pruner: if you can trace his handywork after the trees are all in leaf, depend upon it he wants a cut or two himself. A Spruce tree is a good pattern to go by in pruning boundary trees, only the tiers of branches should not be so regular, nor the regularity of their diminishing lengths upwards so apparent, still, I say this is a very good pattern-tree. When you first begin to thin the head of a young tree is the right time to think of the Spruce pattern, and to follow it out patiently from year to year.

There would be little difficulty in so pruning and training a young Oak as to make it look exactly of the same style of growth as a Spruce—tiers of branches at regular distances, and the branches getting less and less in length upwards, but there is no need for such close imitation; all that I want to impress on the young pruner is, that there is nothing in the nature of our deciduous trees to prevent him from giving them the same form as the Spruce has by nature; and, then, knowing he has this power, I want to teach him also not to make bad use of it, or to blame THE COTTAGE GARDENER if he does. A genial soil, and good brains, help to cover every brick in a fruit-wall; but the best brains, contending against bad soil, find it a difficult matter to make a decent appearance. None of this difficulty, however, affects our pruner on the present occasion; if branches come at all, he knows they must have space enough allowed them to expose their leaves to sun and light, and if more branches come and crowd the necessary space, he knows he must prune off the supernumeraries. He knows, also, that main branches will grow in size, and extend in length, just as trees do, and he prunes them from the beginning as he would thin a thick plantation. In course of years, he finds the side-branches on the main limbs require exactly the same kind of management as the large limbs when they were mere branches did at the first setting-off, that is, they, too, get crowded, and must be thinned, else their closeness, and consequent shade, will soon spoil other branches which he cannot well spare, and so he removes them as often as they interfere with his plans, so that, in fact, the proper thinning of the head of forest-trees, and all other trees, according to their natures, is the main and grand secret of the pruner's art, and the last thing that is thought of, when we want to make a pruner of a country bumpkin, or of my lord Duke, with his thousands of acres, who, if he thinks at all on the subject, is perfectly satisfied with his forester, if he, the said forester, knows as much as keeping down aspiring leaders, and cutting off a tier or two, year by year, from the under or lowermost boughs, but that degree of knowledge could be taught to a needle in ten minutes; and it is idle talk, if not altogether shameful, to rail at Royal Forest Commissioners for doing the very thing that our best books on foresting, until a very recent date, were teaching, and even insisting ought to be done. The whole thing amounts to that style of writing called "teaching your grandmother." You now perceive a better order of things, and you find fault with her, poor soul, because she did not find it out for herself before your first smile gladdened her very heart.

Yes, and I say it, and I will maintain it, until the end of the war, that the grand secret of pruning lies in the thinning of the branches, first, from the main trunk of the tree, and afterwards from the great limbs into which the first branches grow in the course of years. In short, I hold it as a fundamental rule, that every main branch, or great limb, which is only the same thing, in the head of a tree, requires the same kind of pruning and attention, after a certain age, as the trunk and head required at the first setting-off; and that rival branches, and crowded ones, ought, and must be removed, or subdued, in the one as well as in the other. A healthy tree will always make more shoots, and, consequently, more leaves than can receive the necessary light for the exercise of their functions; or, if they do for a year or two, they get overshadowed after that, and the pruner must remove them in time, rather than allow nature to suppress and kill them in the long run; but all that is necessary to know about thinning, neither science, or a practical pen can thoroughly teach a third party; you might as well try to learn a man to make a military cloak, or Wellington boots, except as far as general rules can teach.

The *Cedar of Lebanon* is often the worst-managed tree in England, while it is young and growing very fast, and the best tree I know of to point to for the teaching of thinning heads and limbs of trees. At the first going-off this tree grows so slowly that the intervals between the tiers of branches is very little, and the branches themselves do not come in regular tiers, as in the Spruce, until the tree has grown freely in its final place, and often not even then, or at any stage of its growth, owing to slight variation in the seedlings, like those of the Scotch Fir. There is one peculiarity, however, in all the varieties of this Cedar, which is much in the favour of the pruner; it bears the knife more freely than any other tree, not excepting the Yew; and, like the Yew, no day in the year comes amiss to it for pruning. I have had a great deal to do with young Cedars of Lebanon in my day, and I am quite sure of all this, and I know that one can give any kind of form to the tree by pruning, from the shape of a Currant bush to that of the Larch, or Lombardy Poplar; but for illustrating the subject of thinning, I shall suppose the Cedar of Lebanon is to be carried up as the Silver Fir grows—a regular set of tiers at regular distances all the way up, and no small branches left between these tiers, only little stumps of small branches that were stopped early, and the usual tufts of leaves so common on the stem of young trees of this Cedar. A young Cedar of Lebanon, and a young *Wistaria sinensis* are the two most lazy plants we have, if they once take to being lazy; but that is not their natural way, for the Cedar can grow almost as fast as the Larch, and *Wistaria* faster than the Grape Vine. The reason for the slow growth of the Cedar is, principally, that a lot of bottom branches had been allowed to divide the strength and energy among themselves at the expense of the leader, and if they were allowed to stand in a free open space they would keep their advantage for very many years, spreading as far, on all sides, as the leader could rise upwards, and that is the reason why you see so many of them flat-headed. But cut out one-half of these bottom shoots, and stop the point of the other half, and away goes the leader immediately; and if you were to cut off every one of them, the leader would go quite as fast, that I am quite certain of; but then the want of bottom branches in a young Cedar-tree would look bad, besides hindering one from making a good specimen of it. The best plan is to fix on what is to be the lowest tier, and cut all the rest into within four inches of the trunk; the stumps, being all covered with leaves, will keep alive as long as you please without increasing in diameter, so that when you come to cut them off quite close the wood will be small

and easy to cover. This stopping process, or stumping, is often obliged to be resorted to by the best forest pruners when they have to deal with trees; I mean, any forest trees that have been long neglected. There is so much thinning to be done at once, that if the one-half of it were done in one season, many trees would suffer severely from it, and so they hit on this stumping plan, to arrest the swelling of such branches as they intend to remove ultimately.

D. BEATON.

(To be continued.)

LOOKING AROUND US.

THE last three weeks have been trying ones to the patience of anxious amateurs—the let-well-alone policy is one they are very slow to learn. Many an anxious look has been given to plants in cold-pits, when true prudence would have kept the glass shut, and the covering untouched, except for turning and breaking it. Writing this on the 9th, it is now more than three weeks since the plants in our cold-pits saw the light of day. I know the inside was cold enough, and, therefore, no air was necessary. The snow constituted a valuable protection until the 7th, when it began to melt rapidly. I have glanced in at a corner or two, and have no reason to be alarmed, but, as the covering is not thoroughly thawed, I shall leave it as it is a day longer. When first uncovered, if the day should be sunny, a little shading will be necessary. Air, too, after such confinement, should be given gradually, not too much at once. I mentioned, the other week, the importance of giving a little air, even if the covering was kept on several days, whenever the temperature within was high enough to encourage growth. The first opportunity should be taken to remove every damped or decaying leaf. In all structures capable of being heated, the keeping constantly covered would neither be necessary nor useful; but in severe frost, as we have had, the thermometer sinking from 10° to 22° below freezing, covering the glass, where practicable, becomes both useful and economical. The plants are not dried and drawn, and the coal-heap is saved; besides, a minimum of attention is required. Large fires pre-suppose frequent waterings, and admittance of air, too, when the plants would have been better in a cooler atmosphere, and without the admission of dry, frosty air. Hence, in a greenhouse, kept in mild weather at from 45° to 50° at night, I would prefer that that house should range from 35° to 40° during a few nights, with 10° to 20° below freezing out-of-doors. A gardener lately wrote to me, that he had covered all the pits and houses he could, though he could heat them, and he was sure, that with an outlay of a few shillings on litter, his plants would look better than some of his neighbours, who, in similar structures, had kept out frost by the cost of many pounds for coals alone.

Watering.—In cold pits, little of this will be required for some time to come. When the weather brightens, and a plant, or pot of plants, gets dry, it is best to lift the pot out, and replace it when drained. In houses heated, watering will be most wanted where the flue or pipe is hottest; and whatever needs it should have enough at the time to reach every root. In the case of a flue, the necessity of frequent waterings should be avoided in severe weather, by having evaporating pans, or vessels filled with water, set over the heating medium. This will prevent the atmosphere being dried. In mild weather it matters not whether these vessels are full or empty, as if there is no fire-heat evaporating from them will proceed but slowly. Much care is necessary in watering all greenhouse plants in frosty weather, and an effort should be made to spill as little as possible. A

little fire-heat with a frosty air outside dries the soil in pots very quickly. Such things as Cinerarias, Geraniums, and soft-wooded plants, show this before much mischief can be done; but in the case of Heaths, Chirozemas &c., if you wait until you see the flagging signs of dryness, you may pretty well take them to their last resting-place at once. Fine specimens of these should be examined by weight and striking their sides with a knuckle almost every day. In the case of the whole of the pea-blossomed fraternity of compact hard-wooded plants, such as *Gastrolobium*, and other allied genera, with a similar termination of "*lobium*," as was long ago demonstrated, they must neither be dry nor soaked, or the rootlets go to a certainty. Drainage, therefore, must be perfect; and, at times, the means mentioned the other week must be resorted to in watering, when the specimen is large. Any one of our readers as fond of fruit as they are of flowers, and who have succeeded in gathering Strawberries from January to March from plants that were runners the previous season, will have no difficulty in keeping these hard-wooded plants in just the right condition. Copious and good directions have been given about Strawberry growing, but when wanted early, a vast deal depends upon the watering. If left too dry, the fruit embryo is dried up; if too wet, a gouty dropsy is the result; and in winter especially, the disuse, or the ill-use of water affects injuriously our pot plants. Let the water during winter be always a few degrees warmer than the house.

Plants in Windows.—Judging from what little we have seen of window-gardening, many of our friends will have to visit the plant stores next season. Large fires, the dry air of the room, and the neglect of the water-pail at the roots, and the sponge over the foliage, have left nothing but dried skeletons, where a month ago all was fresh and luxuriant. The soil, in some cases, had been of a loamy character, and so thoroughly baked and hardened had it become, that with neither finger nor nail could I make an impression upon it. Whole tribes of Geraniums, Myrtles, &c., were not worth a brass farthing. Fuchsias presented the only hope, inasmuch as there might be vitality below the soil, though there was none above it. Others, to save trouble, had for three weeks kept their window-plants on the chimney-piece, or in a recess by the side of the parlour chimney, and their dusty, weakly aspect was enough to give one the blues.

A few, copying the example of our old friend, *Mrs. Think-in-Time*, had plants in their rooms almost sufficient to make us blush for our own. No dust had been allowed to fall upon them; the leaves had been sponged every week; the roots had been watered just as they needed it; not a vestige of a yellow leaf was allowed to remain; every possible ray of light was given when safety from frost was secured; and when cold was apprehended the plants were removed from the window, and covered up at night. The first mild sunny day the window will be opened a little, and by-and-by the plants will be set outside. Plants in living-rooms, however, suffer but little from close vitiated air; every opening of the door brings a fresh supply. It is the heat, and the dryness of the air from the fire that injures them; and these can only be counteracted by nearness to the glass in the day time, so as to cool, as well as have light, and a damp atmosphere by sponging and sprinkling the foliage.

Manure Water.—This, in a weak state, will now be of advantage to Cinerarias coming into bloom, Camellias in bloom and opening their buds, Chinese Primroses, Ageratums, Salvias, *Tropæolum Lobbiaua*, *Lachenalia* showing bloom, *Cyclamens ditto*, Perpetual Carnations, Pinks, Scarlet Geraniums in a blooming state, &c. Most other things in a greenhouse should have clear soft water at this time.

Syringing.—This will be generally advisable, when, after some dull days, we have a sunny one—very likely the forerunner of a frosty night. If plants are as dry as safety will permit, they will stand an amount of cold they could not do when wet. In dull, foggy weather, the whole perspiring and elaborating processes of this plant are reduced to a minimum. A bright sun comes upon such plants, and finds them unprepared to meet him, and before their dormant energies are aroused, he makes them hang their heads like bulrushes. Now, ten to one, the plants do *not* require moisture at the roots, and a drenching there, with a frosty night succeeding, might require as many more coals from you as would keep a parlour fire for several days, if your house was large. A slight dusting over the foliage, in such circumstances, just as the sun begins to shine forcibly—nay, repeating the operation at mid-day, if necessary—would supply moisture for him to evaporate, without extorting it from the debilitated stems and foliage of the plant. Upon the same principle, after dull weather, we are often forced to shade tender plants from a bright sunshine, not because sunlight is not good for them, but because they are not prepared for its free action. Extremes must be avoided.

Air-giving.—This is another puzzler. I have mentioned, when in cold pits they may be shut up, and when air *must* be given. As a general rule, with an outside temperature of 36° to 40° in the shade, air may be given freely; but so as to keep out wet. With that temperature, and foggy, give none if you can keep the fog out; give a little if that is beyond your power. In cool greenhouses act on the same principle. Where plants are in bloom, or plants are forced, air must be given with more caution. Give little, or none, in very frosty weather; prefer letting your fires low during the day; and, if practicable, cover up at night. If several days of raw, cold, damp fog come, keep it out if you can. If it gets into the house, light fires to change the fog into invisible vapour, and give a little air at the top, just to let the moisture-laden air escape. This will prevent the evil of a stagnant atmosphere. With an outside temperature of 40°, and above, give air freely. When much below that, a free admission of air, except for an hour or two, would, in the case of greenhouse plants in general, be attended with a free use of the fuel heap.

R. FISH.

THE WOODS AND FORESTS.

PREPARING THE GROUND FOR A NEW PLANTATION.

(Continued from page 281.)

SUPPOSING the proprietor of some extensive moor, or mountain land, has determined, or been influenced, by some means or other, no matter what, to plant a large piece of those barren and bare portions of his estate, the first thing to do is to prepare the ground for the reception of the young trees. Draining is the first step towards that preparation. Without this important measure being well carried out vain will be the labour and expence of planting. I have, some three or four weeks ago, given an instance of the ill-effects of planting undrained land, and the beneficial effects it had on them when performed.

If the ground, then, is wet and springy, or any part of it, let that part be well and thoroughly drained. It will pay the expence in a very few years by the rapid and free growth of the trees. The next operation will be digging or trenching the ground. This is a heavy and somewhat costly operation, requiring a large amount of labour, and a no less large share of patience and perseverance; but wherever the spade and pickaxe can be used, the land intended to be quickly covered with timber must be digged, or even trenched. Far better

is it to only undertake to plant five acres at once, and do it well, than to plant fifty carelessly prepared. The practice, when I was a boy, was to let to nurserymen, by contract, a certain number of acres to be planted at so much an acre; the nurseryman to find labour and trees, and to fill up all vacancies that might occur through deaths for three years. This seemed a very excellent plan; and where the land was tolerably good, in some ten or fifteen years a fair sprinkling of trees did make some growth.

I was then in a celebrated nursery in the north, and often had to attend upon the men and carry plants for them. Previous to planting, a kind of pioneers were sent to what they called prepare the ground by *holing* it. This work was commonly done about August and September. If the ground would allow it, a turf, about a foot square, was cut off the surface, the soil underneath thrown out, and then the turf put into the bottom of the hole, and the soil upon it; but if the land was thin of soil, covered with brushwood, or fern, the *holing* was then done with a kind of mattock, one end of which was like a strong, thick hoe, and the other sharp and small, like a common pickaxe. With the broad end of this certainly powerful tool in the hands of a strong, willing man, the turf, or fern, was chopped off in a circle about a foot or fifteen inches diameter. Then the soil, or gravel, or marl, or whatever was underneath, was loosened with the sharp end of the mattock, and the hole was ready, as they said, for the tree. This operation was often relet by the nurseryman, and was, or was not, properly done, as the case might be. The price, if I remember rightly, was miserably low, so that too frequently the men only half did the work, in order to count a greater number of holes, and thereby earn more, or, at least, obtain mere of their scanty pittance. Then, when autumn arrived, the trees were torn up out of the nursery beds, a kind of hodge-podge mixture was concocted, and the trees were thrust into these prepared holes or holings. The men should have opened the holes deep enough for the roots, then set the tree in the centre, and fill in the loosened stuff, whether gravel, sand, or soil, or a mixture of all upon and amongst the roots; but too frequently, in order to get in a certain number before night, the spade was merely thrust in about the centre of the loosened soil, worked backwards and forwards, till a kind of chasm was formed; then the roots were crammed in and the soil closed, and this was called preparing and planting a forest.

In some situations this mattock would be an excellent tool, no doubt, for preparing the ground, and the previous summer a proper season to do the work in. Steep hill sides, covered with small stones, with here and there patches of gorse heath and rough grass, in such places this mattock would be the very best instrument for the purpose; but then the whole surface should be mattocked over, and all brambles, whin bushes, or heath, stubbed up, and either burnt or laid in heaps to rot. With this instrument the most barren hill, or mountain, might be prepared, so as to receive and grow trees well.

It is well known to many persons that in Hampshire there are large tracts of hilly land on which there is the scantiest of all herbage, and scarcely an inch of mould. About forty years ago, the late Lord Calthorpe came into possession of a large tract of such land in that county. He was then a young, enterprising man, full of benevolent feelings for the poor on his estate, and therefore he immediately set them to work in preparing the barren parts of it for the reception of trees. So little soil was there that every particle that could be found was laid in little heaps, and when the planting was commenced not more than a spadeful could be allowed to each tree. Yet, so well were they planted and managed under his own eye, that ten years ago, when I sojourned for a short period in the neighbourhood, the

trees had progressed so as to give the what was once a bleak waste quite a woody appearance. These hills are now covered with very fair timber, and this instance of great success in making the wilderness to smile, even in the owner's life-time, ought to stimulate all proprietors of waste lands to go and do so likewise.

T. APPLEBY.

(To be continued.)

THE TUBEROSE.

This fine, sweet-scented flower, *Polianthes tuberosa* was introduced from the East Indies so long since as 1629. The tuberous roots are grown in Italy as an article of commerce, and are brought over in considerable quantities to this country annually. They are mostly imported by the Italian warehousmen in London, and come generally along with Orange and Lemon-trees, the large flowered Jasmine (*Jasminum grandiflorum*), and the Arabian Jasmine (*Jasminum Sambac*). As this is the season to purchase the roots of the Tuberose, and plant them, I trust a few remarks on its culture will be acceptable and useful to the readers of THE COTTAGE GARDENER.

Soil.—The soil I have found to suit them best is a rich, alluvial loam, mixed with about one-fourth thoroughly decomposed hotbed manure, or two years' old cowdung, well reduced, will answer admirably. If the loam is not naturally sandy, a sufficient portion should be added to the compost. I find river-sand, sifted so as to clear it from stones, the best kind of sand for the purpose.

Pots.—The diameter of the pots should be, for one tuber, 5 inches; for two, 7 inches; and for three, 8½ inches. The pots should be chosen as deep as possible, because the roots of the Tuberose, like all other bulbs, descend rapidly and deeply into the soil. The pots should be used quite clean, and must be well drained. Previously to potting the roots all the small side-shoots should be carefully rubbed off, as well as all the remains of the old withered roots and leaves. This dressing of the bulbs must be done with care, so as not to injure or wound the main tuber. The Italians, I suppose, send them over with all these excrescences on them to make them look larger, or, perhaps, to preserve the main tuber. When they are thus cleaned let them be potted.

Planting.—Fill the pots with the soil, and press it firmly down, leaving the pot so full as to allow the neck of the tuber to be level with the rim of the pot; then insert one, or two, or three, as may be thought most convenient, in each pot in proportion to its size, filling the earth in firm round each tuber. I have grown them equally well in all the three sizes, but for placing in a conservatory, when in bloom, I should recommend the largest size, and three tubers in each pot. The tuber only produces one flower-stem, though each stem produces sometimes as many as ten pairs of flowers.

Varieties.—There are two varieties, namely, the single, and double. The latter, generally, is preferred, though I think the single equally beautiful. The flower-stems rise to the height of from three to four feet, and, consequently, in a conservatory, the pots should be on a level with the floor, to bring the flowers nearer to the eye; hence, three flower-stems show much finer and to greater advantage than one. When used only as cut-flowers, the one-tuber-in-one-pot system might be adopted. I imagine the flowers are somewhat finer and larger by that method. Where few are grown, too, it may be desirable to put one or two bulbs only in each pot. A succession of bloom may be obtained by potting a batch in February, and a second in March, and a third in April—later than that will not answer well. In order to be certain of a good bloom choose the soundest

tubers only. If the central part feel soft, or is decayed, throw such away at once—they are worthless, and will only disappoint the cultivator if potted and attempted to be grown.

Culture.—When all are potted, then plunge them in a very moderately-heated bed of tanner's bark, or fermented leaves. I always plunged them in such a bed made in a deep pit, and seldom failed to bloom every tuber, though I have frequently witnessed a failure where they were merely potted and kept in a warm house without plunging. Of course, the different batches to be bloomed in succession were plunged at different times. And here I would remark that this East Indian plant would do best by being excited into growth by bottom-heat, whilst such bulbs as the Hyacinth, Narcissus, &c., require, previously to being placed in heat, plunging in a cold material, until new roots were formed, whilst the Tuberose requires a moderate bottom-heat at first to start the roots into growth. As soon as the leaves begin to spring from the top of the tuber then commence watering, giving small quantities at first, and increasing as the growth advances. Numerous leaves soon appear, and when the growth is vigorous so that the leaves require a large amount of support, then give the plant some weak liquid-manure every third time of watering.

As the season advances give plenty of air on every fine day to prevent the leaves from being drawn. The flower-stems will soon be seen pushing up from the centre of the leaves. They must be watched daily (for they grow very quickly), and as soon as they come to within six inches of the glass lift them carefully out of the pit. It will be found necessary to place a stick in each pot, and tie up to it all the leaves, as well as flower-stems, nearly their whole length, or they will infallibly be broken if removed without this precaution. Place them in a warm greenhouse, or intermediate stove, for having got the flower-stems fairly started they are sure to bloom. The great difficulty is then overcome. Afterwards, give plenty of water, and use the syringe freely, to prevent the attacks of the red spider, till the blooms begin to open, when the syringe must be dispensed with, and the plants removed into a cool greenhouse, or conservatory, to prolong the bloom.

The late R. Salisbury, Esq., wrote a long paper on the culture of this plant, so as to bloom the young sucker, and thus save the trouble and expence of importing them; but really the price of imported full-grown blooming bulbs is so reasonable, that the saving is very questionable; the nurserymen only charge four shillings a dozen for such roots. Now, to grow a sucker, or side-shoot, from its being separated from the parent bulb to blooming, requires a large amount of care, trouble, and expence; and at least three years, even if successful, to accomplish it. I think there are few cultivators, if any, that would not buy them full-grown and ready to flower at once, rather than be at all this trouble and expence of growing the small roots into a blooming state.

T. APPLEBY.

SEA-KALE.

It has been justly observed that there are few things which are not better when grown in a natural way than forced, but one of those few is, assuredly, "Sea-kale,"—not that it is entirely useless grown in a state of nature, but that it does not then possess the qualities we have long looked upon as constituting its principal merits. One of these qualifications is that crisp tenderness which in a blanched condition it receives, differing in this respect from Asparagus, which, when not allowed to show its head above ground, is said to eat sticky and tough, the under part being, in fact, unfit for food.

However, the reverse is the case with Sea-kale, for with its fibre and other woody matter would seem to be more fully formed when exposed than when blanched up in the confined manner it is when forced into use; nevertheless, means may be taken to direct the efforts of nature to produce a different article, as by covering over the crown of the plant with something that will exclude the air a certain degree of blanching takes place, depriving the young shoot of the woody fibre and the strong taste, which, in common with some other members of the Cabbage family (to which it is in some degree related) is much diminished; and the article, with good management, has all the crisp tenderness of the forced production, with more of the vigour and strength of the last-named than the more forward crops could boast of. Now, as this is easily attained by very humble means, and coming into use when ordinary garden vegetables are far from plentiful, it may not be altogether useless here to point out the way, adding a few words, in the first place, on forcing in general.

For the earliest crop of Sea-kale, I have, for many years, been of opinion that plants reared on good ground in one season, with single eyes, and of such a size as to resemble tolerably well-grown Carrots, are best adapted for the first crop, by being taken up carefully and inserted in soil that is heated in some way for that purpose. The amount of warmth necessary is much less than is often supposed—nevertheless, it must be forthcoming, or the result will be unsatisfactory. However, there are often odd corners in which a quantity might be stowed away with ease, which could not be made available for anything else. The mushroom-house is often applied to this purpose, and is a very good place, as is also any heated corner in connection with the hothouse fire, as the amount of heat is the only requisite qualification, light being of no consequence—in fact, it is better without it, except so far as arranging the plants and examining them afterwards is concerned. For early work, the plants ought to be taken up as soon as the leaves drop off; in other words, “when they are ripe;” and it is of the greatest importance to take them up with as little injury as possible—for, as the future produce is, in a measure, the development of the stored-up matter contained in the crown, or incipient bud, assisted by what little nourishment the plant can draw from the medium it is placed in, it follows that the latter cannot be expected to supply much if all those small rootlets, which ramify in various directions for food, be all cut off in the taking up or replanting process, and, as they are very tender, and easily broken, it requires great care to ensure their doing well. Some growers put the roots in pots—some half-a-dozen roots, or so, in a large, deep one; but as these must be very large, and difficult to remove, I have generally contrived to do without them, by planting the roots tolerably thick on the heated place, giving a final coat of ashes at last, and over this something that will keep the place dark, and somewhat moist: some very homely contrivances will effect this well enough.

It would be as well to remark, here, that when a supply of plants like the above are wanted yearly, a corresponding quantity must be sown every spring; and, as I have observed they may be reared in one season, it is only fair here to observe that it is only on good ground that such can be done, and, when that is not effected, two-year-old plants must be substituted—these, however, have generally more crowns than one to a root, and, consequently, are not so good. Nevertheless, they may be used when single ones are not to be had. It is almost needless here to observe, that in preparing plants for forcing the seed should be sown where the plant is to remain, and, by being properly thinned in time, a good, useful produce will generally follow. Very small plants, standing one year, may be

transplanted during winter, and in summer, by being regulated a little in the way of curtailing the head, a very good plant may be obtained for forcing.

For the later crop, beginning with February, and following on to May, plants in the open ground may be more advantageously forced in country places, where leaves or other heating materials are at hand, by being covered up with the heating matter, pots being placed over the plants, with lids, &c., as is generally known, and the heating matter being applied between, imparts a warmth to the ground which urges on the growth of the new vegetable in such a way as to bring it to a size fit for table in about three weeks or a month after the fermenting matter has been applied. This, of course, will depend upon other circumstances as well, only let it be remembered, that after January the amount of heat requisite for forcing is much less than before that period, and the plant is also much better able to endure the process than when done earlier, and the produce is also considerably stronger, and gradually improves in that respect as the season advances, and forcing becomes a mere matter of assistance. This, however, will be easily understood; and those who wish to have a dish of Sea-kale before Christmas must not expect to have it so strong and fine as if they waited later for it; but the sacrifice is generally made without a scruple.

Much of the well-being of Sea-kale depends on the treatment the plants receive during the summer months. If they are left to run wild, flowering and exhausting themselves in a useless way, the produce must not be expected to be good, as it can hardly be expected that a ripened crop of seed can leave the plant which produced it with all its “stores” unimpaired: on the contrary, the nutriment which ought to have been stored away in embryo has been used to perfect the crop of the past season—on that account, therefore, let no plants seed, unless a few to produce the quantity that may be requisite to sow the crop wanted the following spring. It is scarcely necessary to add, that enriching matter is also needed to assist the growth of the plant, and, if that could be applied at the growing time the result would be more satisfactory. Liquid-manure and a little salt might be applied at that time to advantage, and the ground-stirring, and other modes of good cultivation, being carried out, a crop may be expected; but the usual summer treatment has in other places been dealt with, that it is unnecessary here to repeat it, only it may be worthy of notice to all who are contemplating a new plantation to call their attention to the nature of the ground where this plant is found wild—the sandy shores of the sea-side—and by that they will have a hint what description of soil is best calculated to ensure a good growth afterwards.

J. ROBSON.

MANAGEMENT OF DOWN EWES AS BREEDING STOCK.

(Continued from page 281.)

THE time at which the Tup should be turned in with the Ewes will depend, in some measure, upon the district where they are kept; for, except in those localities where the soil and climate are good, it is useless to attempt early breeding; not only will the habit of the stock oppose this, but the cultivation of the land also, for in cold, backward situations, the stock must depend more upon the summer-keeping, as in that case the greatest increase and requirements of the flock will take place at the period when such land is capable of yielding its greatest produce. Whereas, the better

descriptions of soils may be made to yield the largest amount of produce for Sheep-keeping in the winter and spring months, and are, consequently, capable of sustaining a large increase of stock, although it may take place a month or six weeks earlier than usual. It is, therefore, best to decide upon the breeding season, and regulate it as much as possible according to the influence of the before-mentioned circumstances. The method of feeding and general management of the Ewes, from this period until Lambing-time, having been rather fully treated upon in my former contribution upon their treatment on grazing farms, I intend, now, to make only a few general observations, showing the distinctions necessary to be made between a Grazing and Breeding flock. In the breeding flock there is always a proportion of young Ewes, which circumstance, coupled with the fact of the difference in the nutritious and forcing properties of the food produced upon grazing, as compared with breeding, districts, greatly reduces the risk of disease and loss in the latter at the Lambing time, particularly if due regard be paid to keeping of the flock, and to the change of food, and regularity in the time of feeding,

I must, however, here remark upon the practice of stock breeders who feed their meadow-land in the autumn and winter months; for I have known flocks often become unsound from this circumstance, when the season has been continuously wet. Yet it is not, in my opinion, the mere fact of feeding the stock in the meadows which has induced the Rot, or disease of the liver, so much as the want of judgment displayed by the flockmaster, in not allowing a regular change of food, whereby the meadow-grasses are made available in conjunction with the produce of arable land at the same time. I hold the opinion, that Ewes, when they are kept entirely in the meadows, in a wet season, for a period without change of food, or lying, will be subject to the Rot; whereas, the produce of the same meadow-land may be consumed by the Sheep, if they had at the same time the produce of arable land, with the further advantage of lying upon the same; and, although strong arguments have been urged in support of the theory that the eggs of the flukes are taken into the system with the grasses of particular localities on which they are deposited, I am of opinion that it is neither more nor less than the animal taking into the system an undue quantity of water, which produces the fluke in the ducts of the liver, this being known to graziers as the incipient stage of the Rot in Sheep.

I must here mention, that the best known antidote to this disease is feeding the animals upon salt marsh-land. Where this is not available, an admixture of a small portion of common salt with their ordinary food is advantageous. I further urge the great necessity of keeping lumps of rock-salt in the field, to which the stock can gain access at all periods of the year.

In continuing the subject, I must here observe, that the Rams must be taken away from the Ewes at such period as may be desirable, for upon most farms it is best that the Lambs should come well together, in order

that they may be all weaned at the same time. From this time, until the Ewes commence lambing, they should be kept in a moderate manner, and with great regularity, having regard to change and variety in food, rather than to the use of gross and luxuriant keep; and it is best to keep them as long as possible upon the grasses, not allowing them roots until necessity compels, and when they are given, the Swedish turnips are the best for the purpose, together with a fair quantity of good sweet hay. After the above management has been carefully carried out, a prosperous and prolific Lambing season may be seasonably anticipated. It will then be necessary to be provided with a sheltered fold-yard, the method of making and conducting which has been described in detail in my former paper upon the treatment of Down Ewes for grazing; in addition to which, I have only to say, that additional space should be provided (in case of inclement weather) for the young Lambs, which, with their mothers, should receive accommodation by shelter and good feeding, until they are sufficiently strong to bear the exposure of open field feeding.

In stock flocks, where the Wether Lambs are reared for sale as stores, they should not be castrated so young as when intended for sale as fat Lambs. It should, therefore, be deferred until the Lambs arrive at the age of six or seven weeks. This method will greatly improve them for grazing purposes; the animal frame being more fully developed, and having more flesh and constitution, they will be able to carry a greater weight of mutton at a given age; and even in the poor state, when offered for sale, the general appearance and outline of the animal will be better appreciated, and rendered more valuable to the purchaser. As soon as the Ewes and Lambs are able to enter the open field for root-feeding, &c., they should be kept in accordance with the rules of useful and moderate feeding; but, in some cases, high and even artificial feeding may be profitably resorted to when the land will bear the excess of manure. That portion of the Ewes which have Wether Lambs and twins suckling, may be advantageously divided from the other portion which have Ewe Lambs, and may be fed with oil-cake, and peas or beans in mixture, receiving also a full allowance of the best hay, and a continuous supply of cut turnips. These being the sale Lambs of the next summer or autumn, they will improve in value in proportion to the food given, if supplied to them with regularity and judgment. The remaining portion of the flock, being Ewe Lambs, may be kept somewhat different, and should have a liberal supply of the best hay, and cut turnips, which food will be sufficient to raise stock of good size and constitution, supposing the ordinary method of feeding has been acted on. The Ewes of both divisions of the flock will do well for themselves, and afford plenty of milk for their offspring, when allowed a sufficiency of turnips, and as much as they can eat of good field hay. They should, however, have common turnips for the first month or six weeks, after that time Swedish turnips are best, which should be continued as long as they possess their nutri-

tious properties, which, by the method I have described in my paper upon the preservation of Roots, they will do until the middle of the month of May. And, indeed, from the middle of the month of April, where farms have water-meadows attached, the Ewes and Lambs may have hurdled-off for them a portion of grass every day, returning to the field for root and hay feeding in the evening. After the Swedish turnips have been all consumed, Mangold Wurtzel will be just coming in season for feeding, and it is an excellent kind of food for the Lambs to have cut and placed in troughs, in advance of the Ewes, throughout the summer, and, by preserving a sufficient quantity, they may be used for this purpose until the Lambs are fit for sale at the summer fairs. I do not hesitate to say, that stock Lambs of the very best description may be made at a far less cost from cake and corn than when they receive grass only in connection with those artificial feeding materials. The green crops of different kinds will now, after the Turnips are gone, be coming into use; and those crops, such as Trifolium, Tares, &c., should be given only as a change, which food they should get hurdled-off for them during the day, and in the evening they should be allowed to return to grass, or Saintfoin, where the Lambs should receive their trough food. This mode of feeding will not only effect the consumption of all these crops in due season, but will furnish abundance for change and mixture in feeding, so essential to the profitable feeding of stock sheep. The kind of food just spoken of will carry the stock on to the period when the Lambs must be weaned; and this is an important operation, and should be done with care and attention. The best rule is to remove the Ewes from the Lambs, rather than the reverse, as the Lambs will be more contented if they are allowed to run and feed in their former haunts; for in case they are taken away from the Ewes, and removed to a strange place, they will become exceedingly restless, and it is often some days before they take to their food willingly. The Ewes, when removed, should, if possible, for a few days be sent to a distant part of the farm, and out of hearing of the Lambs, otherwise the call of the Ewes proves a source of great disquietude to them.

The wool of a stock flock is of great importance in the economy of sheep-farming, and, as it is a double question, I should observe, that upon the hill farms the Ewes should not be shorn too early, as it may be deferred until the middle of the month of June, with advantage to the fleece and the animal. There is, however, another very important operation in connection with the growth of wool, namely, dipping them in solutions of poisonous compounds, whereby the lice and ticks in the wool are destroyed, it being, at the same time, the means of improving the growth of wool, as well as the health and condition of the stock. There are many of these compounds, all containing arsenic, in use, but that known as "Bigg's" is very suitable, as well as the method of dipping by his improved apparatus.

JOSEPH BLUNDELL.

POULTRY SHOWS.

THE CORNWALL SOCIETY'S POULTRY SHOW.—When we hear of a Poultry Society having held its "third" annual meeting, we are ready to assign respectable antiquity to such a body, and enquire, with some interest, into the practical results that may have been thus attained. In the present instance, the "Cornwall Society," being the first institution of this kind formed in the west of England, has reached this point in its career, and not merely has its exhibition, year by year, progressed satisfactorily, both as regards the quantity and quality of the pens exhibited, but the poultry-markets throughout the neighbourhood are now, by general admission, far better supplied than was the case in former years. This latter fact is, after all, the main point by which we must estimate success or failure in these societies; for we are firmly persuaded, that without the prospect of improving our breeds of poultry, in a strictly economical point of view, the denizens of the poultry-yard would never have occupied their present position in the public favour.

The Corn-chamber in Penzance, was, as previously, the site selected for the show, and although an addition of fifty pens appeared in the catalogue, beyond the entries of the last year, abundant accommodation was provided for the whole number.

In *Spanish*, the first prize was withheld in both classes, no pen being altogether free from a ruddy tinge on the faces of some of its occupants. Many of the birds were well-shaped, and shown in good condition, but the absence of a main characteristic of this family could not allow them any higher position.

Coloured Dorkings, both old and young, had the first prize pens from the yard of George Williams, Esq., of Trevince, near Truro, while the second prize fell to some good chickens belonging to Wm. Bolitho, Esq., of Chyandour. On looking carefully at several of the pens in these classes, we would suggest that mere bulk and weight should not alone be aimed at, since form and symmetry may be present at the same time with the former good qualities, and, if so, would certainly be an additional recommendation of the fowl combining these advantages. The higher bred the bird, provided size is duly regarded, by so much the larger quantity of flesh will appear on the more profitable portions of its body, with a corresponding decrease of offal. A glance at the prize Dorkings at the recent Birmingham meeting would fully bear us out in the recommendation we offer to Dorking breeders, to seek form as well as substance.

In *White Dorkings*, which were more numerous represented than usually happens, all the prizes in both classes fell to the birds of Augustus Smith, Esq., of Treseow Abbey, in the Scilly Islands; notwithstanding a rough passage, the winners were in beautiful feather, and from the number of pens claimed must be popular in this neighbourhood.

In the whole class for *Buff Shanghaes*, Mr. Lawrence, of Rosemoran, near Penzance, came first, and beyond all question, his position of honour was duly merited in every respect. The second prize was taken by Mr. Branwell, of Penzance. Turning to the young birds of the same colour, we find the name of the Rev. W. W. Wingfield as the owner of the well-shaped and good coloured birds that took the first prize; while equal seconds were awarded to Messrs. Gittus and Welch. Highly commended, and the more limited token of judicial approbation, appeared affixed to numerous other lots in this division of the show. Mr. Lawrence had a second prize for his *White Shanghaes*, and the names of those who won in the chicken class included the Rev. W. W. Wingfield, Mr. Lawrence, and Mr. Barton, of Truro. To the latter gentleman was also awarded a first prize for his Partridge-feathered chickens, while Mr. Gittus took a second for his pen of old birds of the same colour.

The circumstance of a cold, wet autumn, and, consequently, a late and unfavourable moulting season, has, hitherto, told against the appearance of the adult Shanghaes, and their temporary depreciation in popular estimation, has, therefore, been apparent. Thus, we must say, is evidently unjust towards a race of fowls, possessing, as these do, such undoubted claims to be considered among the most

generally useful members of the poultry-list; and is far more, we think, to be ascribed to former undue claims on their behalf, and extravagant price to which, in many cases, they were run up for the purposes of speculation, than to their having really fallen short of those qualifications which were asserted for them by their wiser friends. In many localities, where a limited range only can be afforded, no fowl will answer better; and since these conditions are necessarily attached to the circumstances of many poultry-keepers, we have no fear but that their merits will long sustain them in their just position.

The *Hamburg* classes formed no exception to the usual character of these birds as at present shown in the southern districts of England, and which we have spoken of as far behind their appearance in their more favourite northern localities. This remark would apply still more strongly to the Pencilled than to the Spangled varieties; among the latter, Mr. Wingfield exhibited a pen of Gold-spangled birds of great beauty, but these having only recently passed into his possession were not qualified to compete for any prize.

But *Game fowls* should have had precedence of *Hamburgs*, in the order of the prize-list; and the specimens of this race that were here assembled had the fullest right to hold their own, for better birds have, probably, never before been exhibited at a merely local show of this description. In the pen of Duckwings, belonging to E. Rodd, Esq., of Penzance, every point required in the Game fowl was seen to the best advantage; it would, indeed, have been difficult to have found a fault of any kind with these truly admirable specimens. Black-breasted reds, with both white and yellow legs, followed in their several pens, the latter taking the lead, though when we came to the chickens the former had the pre-eminence. The whole class was pronounced "highly meritorious," and certainly appeared to us as most fully meriting this commendation.

The *Polands* were also good, especially the Golden, and some *White* birds belonging to Mr. Lawrence; the former being the property of Mr. Burton, of Truro.

Of *Bantams* we can say but little, since they were few in number, and moderate in quality.

Geese, as was fitting with the exhibition of a society whose principal object has been the benefit of the farmer and the cottager, came out in great force, the first prize in the old class, and the first and second, also, in the young, being assigned to Mr. Wingfield; the first-named pen containing Toulouse birds, the second half-bred between Toulouse and the common English Goose, and the third Toulouse again. George Williams, Esq., had a second prize in the first, and was commended in the second class.

We must repeat the Judge's general approbation of the *Ducks*. Mr. Bedford's Aylesbury's were admirable, also the black East Indian, belonging to that same gentleman. Mr. Wingfield's Rouen Ducks were pure specimens of that breed, where form and colour have been but too commonly sacrificed to mere size by the introduction into the yard of large specimens of the common breed, so that both their productiveness and the flavour of the flesh have hence suffered deterioration. The true plumage of the Rouen breed is that of the wild mallard and duck in their respective sexes. Among Ducks of any other variety were several pens of very large dun and brown birds.

In *Turkeys*, Mr. Williams was all-successful, every prize falling to his pens. Mr. Lawrence exhibited, as extra stock, some good American Turkey Poults.

The *Pigeons* well deserve favourable notice, for nearly every class was well represented, and if we give special notice to any, it must not be regarded as any slight to the remainder. Thus, the White Trumpeters, belonging to the Rev. T. Phillpotts, of Porthgwithden, must certainly have honourable mention, for better birds of this variety it has never been our good fortune to behold. The Nuns, Turbits, Owls, Fantails, and one pair of Almond Tumblers, were also of great excellence.

And, now, one short sentence of advice to exhibitors generally. Select your birds that are intended to be sent to an exhibition with greater care. If it is worth your while to send any, it is surely worth your while to send the best, and for you, or those who have the charge of them, to see to their being properly matched to each other. How

much disappointment follows a neglect of this caution, the echoes of any exhibition would easily testify; with two or three good birds there constantly appears one so manifestly deficient in important points, that the whole pen is unavoidably passed over, and a more even pen of birds, possibly inferior to some in the defective pen, is justly preferred. Again, do not keep up, or "fat" your birds for exhibition; a little extra care, a little more nourishing food may be advisable, but there is no intention, on such occasions, to show "fat" poultry, and birds in this state will neither appear to so much advantage as those with whom little beyond their ordinary treatment has been had recourse to; nor are they in an equally safe condition to encounter the fatigue, and consequent disease, to the chance of which, after our utmost care, they must be subjected by so violent a change in their usual habits and treatment.

By this time the points of excellence should have been sufficiently understood to prevent the annoyance of defeat where green or olive-legged White Shanghaes, Polands with bronzed wings, White Dorkings, and White Bantams with blue legs, and other similar apparent imperfections have marred the effect, and lost the victory, to other really good specimens in the same pen.

To the judge, James Furneaux, Esq., of Scilly, near Plymouth, the author of the useful and amusing pamphlet, "*The Poultry Pentologue*," the thanks of this Society were justly rendered, the decisions being such as might have been anticipated from a gentleman who has studied this subject with such long-continued attention.

TRURO POULTRY SOCIETY.—The Second of the Annual Poultry Exhibitions, which it is proposed to hold at this town, came off on the 5th and 6th of January last. A considerable increase in the number of the pens occupied over those of last year, and the general character of their tenants, evidenced the continued attention of the poultry-keepers of the West of England to the objects of their care.

In the adult *Spanish* there were seven pens, of which, No. 11, belonging to Mr. W. G. Bennett, of Truro, took the first prize; the second falling to Mr. Blee, of Penzance. The chickens of this breed were of moderate quality, and the rubicund countenances of even the prize-birds were very far from what we should desire to see in specimens occupying that position.

When we come to the *Coloured Dorkings* we must reiterate our opinion expressed with reference to this same family at the Penzance Exhibition, for they were generally coarse, and in indifferent feather; and the introduction of better blood is here manifestly required. The pens of the *White* variety were far better filled; and here Mr. Smith, of Scilly, was successful in the old birds; Mr. Hawke, of Truro, in the young.

In the adult Buff *Shanghaes*, we should have been inclined, we think, had the choice been permitted us, to have taken pen No. 43, belonging to Mr. Lawrence, of Penzance, which received the second prize, rather than that belonging to Messrs. C. E. Andrew and Co., No. 41, which was placed above them on the prize-list, since in point of form, feather, and condition, they appeared to us of greater merit, although it might, certainly, be urged, that Mr. Lawrence's pens had somewhat too much cinnamon for the cock. In chickens of the same variety there were many meritorious birds exhibited, Mr. Blee, of Penzance, taking the first prize, with the same birds, as we believe, that carried off the second prize at Penzance last week. In both these last classes there were many commendations, and notwithstanding the late unfavourable moulting season, the condition of the specimens was generally good, although, in several instances, the presence of a faulty bird, as too often happens, ruined the pretensions of companions that might otherwise have been distinguished. The brown and partridge-feathered pens, beyond a good cock belonging to Mr. Burton, of Truro, in No. 79, contained nothing calling for especial notice.

White Shanghaes were very fairly represented, and the Judges were probably occupied for some time with the prize pens in either class. If our adherence, indeed, to the judgment ultimately pronounced is a matter of doubt, we would much rather assign any difference of opinion to the fact that our inspection of the competing pens took place by gaslight only, when many points are necessarily the more involved in doubt.

Game Fowls generally were good, and the first prizes, in both the adult and chicken classes, were allotted to pens belonging jointly to the Rev. W. Wingfield and Mr. Pascoe Grenfell, of Gulval; and Mr. Mitchell, of Truro, took a second prize in the first-named division.

The *Golden Pencilled Hamburgs* deserved their honours, Mr. Miller, of Truro, receiving the first, and Mr. Grenfell the second prize for old birds. A first prize was also awarded to the Rev. W. Wingfield for his golden-spangled specimens.

The *Silver Hamburgs*, however, did not rise above their usual level in these parts; while *Polands*, the white-crested black excepted, were good.

The entries for "any other distinct breed," seemed, in several instances, to have been made without due reference to the regulations, since "cream-coloured *Polands*" should have appeared with "*Polands of any other variety*," and "*Golden-spangled Pheasants*" should, of course, have taken their place along with the *Hamburgs* of that denomination. Three pens of "*burn-door-fowls*" were also here submitted to inspection, but surely their owners were over-confident in claiming for them the dignity of a "*distinct breed*."

Bantams were but an average lot; but many of the *Ducks* were meritorious; while *Geese*, being limited by the prize-list to "*birds exceeding one-year-old*," were necessarily limited in number; we are at a loss, indeed, to understand the reason of this restriction, for *Geese* of the year, if not allowed a separate class, should, at least, be permitted to compete with their seniors.

Turkeys were numerous and good, and among the *Pigeons* were many excellent specimens.

Class 46, for "*extra stock*," had the following notice appended in the prize-list, "Extra prizes will be awarded to any deserving specimens of Water-fowls, Pheasants, or other birds, but all fowls, Bantams included, must be shown in the regular classes appointed for them." We were, consequently, surprised to find pens of *Shanghaes*, *Dorkings*, *Game*, and *Bantams*, in this division. For many reasons, we apprehend, it would have been more desirable to have adhered to the strict letter of the regulations. "*Peregrine Falcons*," strange neighbours to the poultry, here received a prize.

*Brahma Pouter*s and *Spanish* were exhibited by Mr. F. Simons, of Birmingham, to whom, in conjunction with Captain Mansell and Mr. Seldon, of Falmouth, the task of adjudication had been confided.

The Secretaries, we fear, must have had an arduous duty imposed upon them, since the Market-house, in which the Show was held, could not be given up to them for their preparations till nine o'clock on the evening immediately preceding the day of exhibition, and as the birds were to be in their pens by eleven o'clock on the following morning, it is highly creditable to those gentlemen, Messrs. W. H. Jenkins, and John R. Paul, that the necessary erections were completed within the proper time. The Judges, also, must have worked hard to have finished their arbitrations within the period allotted to them.

In one respect, the Truro Society have deviated from the usual routine lately followed by Poultry Associations, for their prize-list divided the several varieties into two classes, that for "*birds exceeding one year old*," and "*chickens hatched in 1853*;" but, at the same time, their second rule stated that "*chickens of 1853 can be shown in the classes for fowl above one year old*." Now, surely, if separate classes are allotted to the adult and young birds, it is far better to keep them apart, and this not less for the sake of the exhibitor than of the judge; while the prize-list and catalogue, as above quoted, seem to contradict each other, since the wording of the first-named class, if intended to admit chickens, should have been not "*birds exceeding one year old*," but "*birds of any age*."

The prospects of the present year, as based on the results of that which has just closed, are most encouraging to Cornish Poultry-keepers; and we trust that another season will so enable them to mature their arrangements, that other counties may be induced to contribute still more largely to these annual exhibitions.

Class 1.—SPANISH.—First prize, Mr. W. G. Bennett, Truro. Second prize, Mr. Alfred Blew, Penzance. Class 2.—CHICKENS OF 1853.—First

prize, Mr. John Thomas, Truro. Second prize, Mr. W. J. Lawrence, Gulval.

Class 3.—DORKINGS (Coloured).—First prize, Mr. G. W. Williams, Trevince. Second prize, Mr. G. Williams, Trevince. Class 4.—CHICKENS OF 1853.—First prize, Mr. George Williams, Trevince. Second prize, Mr. James Gatley, Truro.

Class 5.—DORKINGS (White).—First prize, Mr. Augustus Smith, Scilly. Second prize, Mr. G. Williams, Trevince. Class 6.—CHICKENS OF 1853.—First prize, Mr. Charles Hawke, Truro. Second prize, Mr. W. H. Christie, Truro. Extra second prize, Mr. Augustus Smith, Scilly.

Class 7.—SUANGHAE OR COCHIN-CHINA (Buff or Cinnamon).—First prize, Messrs. Andrew and Co., Redruth. Second prize, Mr. W. Lawrence, Gulval. Class 8.—CHICKENS OF 1853.—First prize, Mr. Alfred Blew, Penzance. Second prize, Mr. Edward Burton, Truro.

Class 9.—COCHIN-CHINA (Brown).—First prize, Mr. E. Burton, Truro. Second prize, Mr. Sydney Godolphin, Tremough.

Class 11.—COCHIN-CHINA (White).—First prize, Mr. E. Burton, Truro. Second prize, Mr. W. Lawrence, Gulval. Class 12.—CHICKENS OF 1853.—First prize, Mr. E. Burton, Truro. Second prize, Mr. W. Lawrence, Gulval.

Class 15.—MALAYS.—First prize, Mr. T. Maync, Penzance.

Class 17.—GAME FOWL.—First prize, Rev. W. W. Wingfield, and Mr. P. Grenfell, Gulval. Second prize, Mr. H. Mitchell, Truro. Extra prize, Mr. W. Pascoe, Feock; ditto, Mr. W. Rooks, Truro. Class 18.—CHICKENS.—First prize, Rev. W. W. Wingfield, and Mr. P. Grenfell, Gulval.

Class 19.—GOLDEN-PENCILLED HAMBURGH.—First prize, Mr. T. N. Miller. Second prize, Mr. P. Grenfell, Gulval.

Class 21.—GOLDEN-SPANGLED HAMBURGH.—First prize, Rev. W. Wingfield, Gulval.

Class 23.—SILVER-PENCILLED HAMBURGH.—First prize, Mr. P. Grenfell, Gulval. Second prize, Mr. T. N. Miller, Truro.

Class 25.—SILVER-SPANGLED HAMBURGH.—First prize, Mr. T. M. Hawke, St. Day. Second prize, Mr. T. Woolfe, Redruth. Class 26.—CHICKENS OF 1853.—First prize, Mr. E. Burton, Truro. Second prize, Mr. N. C. Stephens, Truro.

Class 29.—POLAND (Golden).—First prize, Mr. E. Burton, Truro. Second prize, Mr. Cook, Truro. Class 30.—CHICKENS OF 1853.—Second prize, Mr. E. Burton, Truro.

Class 31.—POLAND FOWL (Silver).—First prize, Mr. G. Williams, Trevince.

Class 33.—POLAND FOWL.—First prize, Mr. W. Lawrence, Gulval.

Class 35.—FOR ANY OTHER DISTINCT BREED.—Second prize, Mr. A. Smith, Scilly. First prize, Mr. Jas. Groves, Truro. First prize, Mr. Thomas Duustan, Truro. Second prize, Mr. G. Dixon, Truro. Second prize, Mr. H. Edwards, Penryn. Second prize, Mr. T. Gittus, Goldsithney. Second prize, Mr. W. Bennet, Truro.

Class 36.—BANTAMS.—First prize, Mr. H. C. Carnell, Perran Wharf. Second prize, Mr. G. Williams, Trevince.

Class 37.—GESE.—First prize, G. Williams, Esq., Trevince. Second prize, G. Williams, Esq., Trevince.

Class 39.—DUCKS (White Aylesbury).—First prize, Mr. C. Hawke, Truro. Second prize, M. T. Gittus, Goldsithney.

Class 40.—DUCKS (Rouen).—First prize, Mr. E. Burton, Truro.

Class 41.—DUCKS.—First prize, Mr. C. Green, Truro. Second prize, Mr. Hosking, Chacewater. Second prize, Mr. G. Williams, Trevince.

Class 42.—TURKEYS.—First prize, Mr. G. Williams, Trevince. Second prize, Dr. Carlyon, Truro. Second prize, Mr. Edmund Carlyon, St. Austell.

Class 44.—GUINEA FOWL.—First prize, Master Charles Gatley, Truro.

GREAT METROPOLITAN POULTRY SHOW.—No reason can be assigned why a Show of Poultry in London should not excel, or, at the least, equal, the similar display which is held annually at Birmingham. Yet such an equality has not hitherto been achieved, and we hear it asked on all sides, "Why is this?" We do not feel at all inclined to enter upon an explicit answer to this query, but there is some powerful reason existing that keeps away from the London Exhibition pens such birds as those of Captain Hornby, and Messrs. Sturgeon, Peters, Punchard, &c. To secure a better exhibition, there ought to be a powerful Committee of men above suspicion, and who do not flinch from having their names blazoned forth to the world—a Committee not exclusively of exhibitors, and of men more anxious to have an excellent Exhibition than to reap from it some advantage to themselves. If such a Committee, and under Royal Patronage, is formed, we shall have a Poultry Exhibition such as ought to be held in the British metropolis.

At the Show, which endured from the 10th to the 13th instant, both those days included, there were about 1130 pens of poultry, but very many were extra stock "for sale," and of the others there were far too many exhibited in the names of the same few parties, with no other object than to obtain purchasers. This sinks the character of an Exhibition, for it is bringing it down to the level of a Poultry Market.

The pens were very well arranged, and the ventilation,

feeding, and careful attendance on the birds, were unexceptionable.

Although there were more than sixty pens of *Spanish* fowls, yet none were equal in quality to those we have seen both here and at Birmingham. Had not the cock in Pen 6, to which a first prize was awarded, lost one eye?

There were about one hundred pens of *Coloured Dorkings*, and among them some birds of great excellence, especially the single cockerels exhibited by Mr. Fisher Hobbs. We never saw finer or better-conditioned birds. They are first cousins of the bird of which a portrait is given in "The Poultry Book." Mr. Hobbs sold three to Prince Albert for £25. *White Dorkings* were few in number, and this was not compensated by quality.

There were nearly 400 pens of *Shanghaes*, and many were very good. All, however, betray a great neglect of attention to improvement of form. Colour has, hitherto, absorbed too much of the breeder's care, but he must now pay the same attention to form, and the same judgment as is shown by flock and herd masters to couple parents together that may combine all desired points in their offspring. Moreover, we saw in many pens all the bad consequences of breeding-in-and-in. The *Black Shanghaes* were very indifferent, and we expect soon to see them entirely neglected. The *Brahma Pootras* were there in some force, and a very varied lot indeed they were. No better evidence of their want of legitimacy could be given than the fact that the first prize was given to birds with Pea-combs, and all the aspect of a Malay tinge; whilst the second prize was given to single-combed birds, of so marked a character, that if only their heads had been seen they would have been taken for Dorkings.

The *Malays* were good, and the cock in pen 615 was as noble a bird as we ever saw of this variety. The *Hamburgs* were, generally, above an average; and pen 780, belonging to the Rev. F. W. Freeman, which took the first prize for *Silver-pencilled*, were very superior. *Polands* were generally good, and we were much struck by the black with black top-knots, belonging to Mr. W. G. Vivian. *Dankums* were generally good also; and the *Gold-laced*, pen 973, shewn by Mr. U. Spurey, were the best of the variety we ever saw. Their delicacy of form, purity of colour, accurate lacing, and high condition, could hardly be excelled. They were purchased by the Queen for £10. The other classes were of average merit, and the *Muscovy Ducks* very superior. There were 425 pens of Pigeons, and about the best collection, as a whole, we ever witnessed.

The novelty of exhibiting single cocks and single hens, we think, was highly successful. They are not so pleasing to the eye as when grouped together; but standing alone affords a stringent test of excellence. None but first-rate birds can bear this solitary display. It enabled many to obtain new blood for their poultry-yards, of which they readily took advantage.

In the "Distinct Breed" class we noticed but one novelty, pen 937, "Ghou Rook Fowls." They are mere toy birds, small, quite black, crested like the Ptarmigan, very short-legged, and rumpless.

JUDGES.—Edward Hewitt, Esq., Eden Cottage, Spark Brook, Birmingham. William Symonds, Esq., 6, Belfield Terrace, Weymouth. Mr. John Baily, Mount-street, Grosvenor Square.

SPANISH.—Class 1.—Cock and two Hens.—6. First prize, Mr. Thomas H. Fox, 44, Skinner-street, Snow Hill. 8. Second prize, Mr. Charles Botham, Wexham Court, Slough. 13. Third prize, Mr. W. F. Fisher, Blandford. Class 2.—Cock and two Pullets.—29. First prize, Mr. Wm. Plummer, Brislington, near Bristol. 50. Second prize, Mr. Edward Owen, 121, High-street, Shadwell. 48. Third prize, Mr. John Taylor, jun., Cressy House, Shepherds Bush. Class 3.—Cock.—55. First prize, Mr. H. D. Davies, Spring Grove, Hounslow. 59.—Second prize, Mr. Joseph Rake, Bristol. Class 4.—Hen.—64. First prize, Mr. William Plummer, Brislington, near Bristol. 67. Second prize, Mr. C. J. Mold, Wingfield Park, Belper.

DORKING.—Class 5.—Cock and two Hens.—91. First prize, Rev. James Boys, Biddenden, Kent. 84. Second prize, Mrs. Finch Noyes, The Cottage, Salisbury. 75. Third prize, Mr. W. Smith, Mays Hill Farm, near Henley in Arden. Class 6.—Cock and two Pullets. 128. First prize, Mr. H. Smith, The Grove, near Bingham, Notts. 135. Second prize, Mr. Edward Terry, Aylesbury. 102. Third prize, Rev. James Boys, Biddenden, Kent. Class 7.—Cock.—145. First prize, Mr. W. Fisher Hobbs, Boxted Lodge, Colchester. 147. Second prize, Mr. W. Fisher Hobbs, Boxted Lodge, Colchester. Class 8.—Hen.—156. First prize, Rev. Jas. Boys, Biddenden, Kent. 159. Second prize, Mr. W. G. K. Breavington, Sutton, near Hounslow. Class 9.—White.—

Cock and two Hens.—173. First prize, Mr. F. Edwards, Bulstrode Park, Bucks. 169. Second prize, Mr. Jos. Jennens, Moseley, near Birmingham. Class 10.—Cock and two Pullets.—186. First prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. 182. Second prize, Mr. H. D. Davies, Spring Grove, Hounslow.

COCHIN-CHINA (Buff and Cinnamon).—Class 11.—Cock and two Hens.—198. First prize, Mr. John Fairlie, Cheveley Park, Newmarket. 199. Second prize, Mr. John Fairlie, Cheveley Park, Newmarket. 206. Third prize, Mr. R. L. Howe, Palgrave, Suffolk. Class 12.—Cock and two Pullets.—302. First prize, Mr. F. C. Steggall, Weymouth. 246. Second prize, Mr. John Fairlie, Cheveley Park, Newmarket. 243. Third prize, Mr. John Fairlie, Cheveley Park, Newmarket. Class 13.—Partridge-coloured.—Cock and two Hens.—345. First prize, Mr. Thos. Bridges, Croydon. 344. Second prize, Mr. John Fairlie, Cheveley Park, Newmarket. 352. Third prize, Mr. Jedediah Strutt, Belper. Class 14.—Cock and two Pullets.—356. First prize, Mr. John Fairlie, Cheveley Park, Newmarket. 361. Second prize, Mr. J. F. Chuter, Haverhill. 362. Third prize, Mr. J. F. Chuter, Haverhill. Class 15.—Cock and one Pullet.—414. First prize, Mr. H. Gilbert, Upper Phillimore Place, Kensington. 456. Second prize, Mr. J. H. Gandy, Old Cleeve, Taunton. Class 16.—White.—Cock and two Hens.—464. First prize, Mrs. E. Herth, Powick, Worcester. 461. Second prize, Mr. W. C. Reynolds, Great Yarmouth. 462. Third prize, Mr. J. Rake, Bristol. Class 17.—Cock and two Pullets.—486. First prize, Mr. John Eason, Montpellier House, South Lambeth. 487. Second prize, Mrs. E. Herbert, Powick, Worcester. 465. Third prize, Rev. S. Allen, D.D., Englefield Green, Surrey. Class 18.—Black.—Cock and two Hens.—494. Second prize, Mr. T. H. Fox, 44, Skinner-street, Snow Hill. (First prize withheld.) Class 19.—Black.—Cock and two Pullets.—508. First prize, Mr. V. W. Blake, 6, Old Square, Birmingham. 507. Second prize, Mr. J. Harding, Brazendroos Road, Norwich. Class 20.—Cock.—515. First prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. 527. Second prize, Mr. R. E. Gibbs, jun., 91, Old Gravel Lane. Class 21.—Hen.—542. First prize, Mr. John Fairlie, Cheveley Park, Newmarket. 550. Second prize, Mr. John Emery, Kempston, Hardwick, near Bedford. (The class meritorious.)

BRABMA POOTRA.—Class 22.—Cock and two Hens. 603. First prize, Mr. H. D. Davies, Spring Grove, Hounslow. 593. Second prize, Mr. H. Gilbert, Upper Phillimore Place, Kensington.

MALAY.—Class 23.—Cock and two Hens.—615. First prize, Mr. William Crick, 23, Warner Place, South Hackney Road. 612. Second prize, Mr. Robert Hedges, 1, St. George's Road, Horsemerger Lane. Class 24.—Cock and two Pullets.—625. First prize, Mr. James Leighton, 183, High-street, Cheltenham. 626. Second prize, Mr. Edward Owen, High-street, Shadwell. (Whole class meritorious.)

GAME FOWL (White and Piles).—Class 25.—Cock and two Hens.—623. First prize, Rev. T. L. Fellowes, Beighton. 630. Second prize, Mr. James Monsey, Norwich. Class 26.—Cock and two Pullets.—636. First prize, Mr. George Hatfield, Doncaster. 638. Second prize, Mr. James Monsey, Norwich. Class 27.—Reds.—Cock and two Hens.—639. First prize, Mr. Henry Thurnall, Royston. 647. Second prize, Mr. E. Farmer, Greet, Birmingham. 644. Highly commended.—Mr. W. Chard, jun., 3, Clifford's Inn, Fleet-street. (This class generally commended.) Class 28.—Cock and two Pullets.—662. First prize, Mr. E. Lowe, Comberford Mills, near Tamworth. 658. Second prize, Mr. G. C. Adkins, Edgbaston, Birmingham. Class 29.—Blacks, &c.—Cock and two Hens.—678. First prize, Mr. Joseph Jennens, Moseley, Birmingham. (Second prize withheld.) Class 30.—Cock and two Pullets.—684. First prize, Mr. R. Choyce, Bramcote Hall, Tamworth. 687. Second prize, Mr. W. G. Vivian, Singleton, Swansea. Class 31.—Greys.—Cock and two Hens.—689. First prize, Mr. H. Thurnall, Royston. 694. Second prize, Mr. H. T. Freere, Palgrave, Suffolk. Class 32.—Cock and two Pullets.—706. First prize, Mr. T. B. Fairhead, Maldon, Essex. 701. Second prize, Mr. James Monsey, Norwich.

GOLDEN-PENCILLED HAMBURGH.—Class 33.—Cock and two Hens.—709. First prize, Rev. F. W. Freeman, Little Finborough, Stowmarket. 708. Second prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. Class 34.—Cock and two Pullets.—719. First prize, Rev. T. W. Freeman, Little Finborough, Stowmarket. 729. Second prize, Mrs. Mills, Bisterne, Ringwood. (Whole class highly meritorious.) Class 35.—Goldenspangled Hamburg.—Cock and two Hens.—742. First prize, Mr. C. J. Mold, Wingfield Park. 734. Second prize, Mr. G. C. Adkins, Birmingham. Class 36.—Cock and two Pullets.—744. First prize, Mrs. H. Fookes, Whitechurch, Blandford. 748. Second prize, Mr. J. Dixon, Bradford. Class 37.—Silver-pencilled Hamburg.—Cock and two Hens.—761. Second prize, Mr. T. McCann, Malvera. (First prize withheld.) Class 38.—Cock and two Pullets.—780. First prize, Rev. F. W. Freeman, Little Finborough, Stowmarket. 770. Second prize, Mr. F. H. Aberdein, Honiton, Devon. Class 39.—Silver-spangled Hamburg.—Cock and two Hens.—794. First prize, Mr. F. Edwards, Bulstrode Park. 797. Second prize, Mr. J. Jordan, Wheeler-street, Birmingham. Class 40.—Cock and two Pullets.—816. First prize, Rev. T. L. Fellowes, Beighton. 806. Second prize, Mr. Jas. Dixon, Bradford.

POLAND FOWL (Black, White-crested).—Class 41.—Cock and two Hens.—819. First prize, Mr. G. C. Adkins, Birmingham. Class 42.—Cock and two Pullets.—828. First prize, Mr. F. Edwards, Bulstrode Park. 824. Second prize, Mrs. Mills, Bisterne, Ringwood. Class 43.—Golden.—Cock and two Hens.—840. First prize, Mr. R. H. Bush, Stiffled House, Clifton. 835. Second prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. Class 44.—Cock and two Pullets.—854. First prize, Mr. W. G. Vivian, Swansea. 848. Second prize, Mr. A. Rosling, jun., Southwark. Class 45.—Silver.—Cock and two Hens.—858. First prize, Mr. G. C. Adkins, Birmingham. 861. Second prize, Mr. S. T. Baker, Manor House, Chelsea. Class 46.—Cock and two Pullets.—874. First prize, Mr. F. Edwards, Bulstrode Park. 878. Second prize, Mr. S. Boulnois, Abbey Road, St. John's Wood. Class 47.—Any other colour.—Cock and two Hens.—884. First prize, Mr. T. Dutton, Streatham Common, Surrey. 883. Second prize, Mr. John Fairlie, Cheveley Park. Class 48.—Cock and two Pullets.—897. First prize, Mr. W. G. Vivian, Swansea. 896. Second prize, Mr. W. G. Vivian, Swansea.

FOR ANY OTHER DISTINCT BREED.—Class 49.—907. First prize, Mr. John Taylor, jun., Cressy House. (Andalusian.) 918. Second prize, Mr. John Fairlie, Cheveley Park. (Scotch Bakies.) 924. First prize, Mr. H. A. Davies, Spring Grove, Hounslow. (Rangoon.) 929. Second prize, Mr. W. G. Vivian, Swansea. (Frizzled.) 932. Second prize, Mr. W. G. Vivian, Swansea. (Normandy.) 937. First prize, Mr. H. B. Higgs, Hill Lodge, Southampton. (Ghon Kook.) 939. Second prize, Mr. J. C. Mold, Wingfield Park, Belper. (Rumpless.) 940. First prize, Rev. T. L. Fellows, Beighton. (Moss Pheasant.)

FOR CROSS BREED.—Class 50.—949. Ten shilling prize, Mr. Thomas Sheen, Aylesbury. (Muffled Dorking and Cochin.)

BANTAMS (Gold-laced).—Class 51.—Cock and two Hens.—973. First prize, Mr. U. Spurey, Market-street, Dunstable. 976. Second prize, Mr. G. C. Adkins, Birmingham. Class 52.—Silver-laced—Cock and two Hens.—959. First prize, Mr. Uriah Spurey, Market-street, Dunstable. 958. Second prize, Mr. James Monsey, Norwich. Class 53.—White—Cock and two Hens.—1000. First prize, Mr. W. Cottis, Witham, Essex. 999. Second prize, Mrs. Caroline Brace, Abingdon. Class 54.—Black—Cock and two Hens.—1007. First prize, Mr. James Monsey, Norwich. 1013. Second prize, F. S. Astley, Esq., Bargh Hall, Thetford. Class 55.—Any other variety.—Cock and two Hens.—1025. First prize, Mr. W. Sidney Forrest, Greenhithe. 1029. Second prize, Mr. W. G. Vivian, Singleton, Swansea.

GEESE.—Class 56.—Gander and two Geese.—1050. First prize, Mr. A. Williams, Reading. 1051. Second prize, Mr. A. Williams, Reading.

DUCKS (White Aylesbury).—Class 57.—Drake and two Ducks.—1056. First prize, Mr. E. Terry, Aylesbury. 1058. First prize, Mr. W. G. K. Breavington, Sutton, near Hounslow. 1077. Second prize, Mr. A. Williams, Reading. Class 58.—Rouen.—Drake and two Ducks.—1088. First prize, Mr. R. Green, Westerham. 1093. Second prize, Mr. B. H. Brooksbank, Titchell, Rotherham. Class 59.—Any other variety.—1098. First prize, Mr. John Fairlie, Cheveley Park. 1105. Second prize, Mr. G. Botham, Wexham Court, Slough. Class 60.—(Muscovy).—Drake and two Ducks.—1118. First prize, Mr. John Fairlie, Cheveley Park. 1120. Second prize, Mr. I. Taylor, Cressy House.

TURKEYS.—Class 61.—Cock and two Hens.—1123. First prize, Mr. John Fairlie, Cheveley Park. 1124. Second prize, Mr. John Fairlie, Cheveley Park. 1130. Third prize, Mr. A. Williams, Reading.

GUINEA FOWL.—Class 62.—Pair.—1137. First prize, Mr. F. Edwards, Bulstrode Park.

ORCHARDS IN KENT.—No. 3.

BLACK CURRANTS.

AMONGST the individual fruits to which the public taste of late years has directed more than ordinary attention the Black Currant stands pre-eminent. Useful alike at the time it is in season, and in a preserved condition, the demand for it has been such as to induce growers to extend their plantations considerably, and as it is well known to be hardy, of easy culture, and speedily comes into a bearing condition, it is probable the supply hereafter may fully equal the demand, but as that business more especially concerns the speculator than the cultivator, I will at once leave the caterer for the public to his own conjectures as to their future wants, and proceed to detail the process by which the fruit is grown so extensively as astonishes some provincial gardeners when they first get a sight of the supplies which our metropolitan markets present during the season.

Commencing, first, with the *situation*, it is necessary to observe that this fruit is but seldom allowed to reign paramount master of the premises it occupies, for it generally is planted underneath some other crop to which it is subordinate, as Apples, Pears, or Filberts, but more generally the two first-named, for the latter prefers a drier soil than suits the Black Currant in a usual way; however, where the wants or wishes of the owner influences his decision, he plants it with the last-named crop as well, otherwise it must be observed that the Black Currant prefers a damp soil, and seems to derive really less injury from shelter than any other fruit we know of. In forming a new plantation of permanent standard fruit-trees, it is usual to plant something as nurses to them, or rather to occupy the ground in a profitable way while the larger trees are progressing, and, not unusually, these temporary trees remain long after the branches of the trees above them have united so as to deprive the undergrowth of all chance of seeing the sun, and yet we frequently see good, useful fruit gathered in such places, though certainly not in the abundance it would have been had it been allowed the unopposed possession of the whole ground, but even under such disadvantages its importance often tells to the grower's benefit as much as its exalted superiors.

When carefully pruned and attended to it bears well in seasons when other fruits are often scanty, and it is seldom that a total failure in this crop takes place, unless under extraordinary circumstances. Certainly, the past season exhibited the Black Currant in a different light than it usually had been seen in before, for at the time when the fruit had been fairly set, and partly grown, a disease, under the incomprehensible title of "a blight," attacked them, and quantities of the berries fell off, leaving the bunches much lessened, in many cases more than half; this disease having much of the mystery of the Potato disease about it, conjectures as to its cause were rife enough, but attempts at its cure or prevention another season were but little attended to. Now, as this disease may make its appearance again, it is only right here to mention it as presenting no features to indicate want of health or vigour in the plant; neither is it confined to those who may be suffering from poverty or weakness, for the healthiest plantations were attacked as well as the neglected or indifferent ones. However, the disease did no farther damage than lessening the crop, for the remaining portion ripened very well, and at gathering time the quantity was not so much below the average as was expected, yet it could not be called more than half a crop.

As I have said, the Black Currant forms a very important undergrowth to plantations of Apples, Plums, &c., its produce is not always the only source of revenue the cultivator relies on, for the other fruits may be abundant, although the present season this was far from being the case; however, there is every reason for believing that the short crop of the past year will in no wise prevent fresh plantations being made, and, like everything else (which there is a remunerative demand for), ground not exactly adapted for Black Currants is likely to be planted with them, and, in fact, has been planted already, but so hardy and accommodating is this production, that it does not seem to refuse to grow anywhere; even in places where nothing else will thrive, it will accommodate itself wonderfully well—on the cliffs of a rock, or the recesses of a dell—on light soil, or on heavy; yet it is only on the latter kind of soil that the quantity and quality of the fruit is according to the standard of excellence we would like to see adopted; only in one respect this fruit differs from most others, for while they are injured by being grown in close contact with trees of another kind, struggling with, and depriving them of much of the nourishment they so much require, this fruit seems to thrive better under the shade of trees than it does alone, provided these trees be not too numerous or encroaching. However, as we have said enough on its general habits, let us turn to the details of its cultivation, which are few and easily understood.

In the first place, it is understood by all not confined all their lives in the recesses of city or factory, that the Black Currant strikes root freely when slips of the current year are put into the ground in the autumn, after they have ripened and shed their leaves; these slips are usually planted in rows about two feet apart, and six or eight inches are allowed in the row; the shoots made the first season are usually cut back the ensuing winter, which cutting back is called *leading-in*; the growth of the second season is generally sufficient to form a tolerable "head," and the plant might then with advantage be taken up and planted in its place, as it is advisable it should not be too stunted. At this planting no cutting takes place, except any very disorderly shoot may be cut out, but none are shortened; neither is it common to shorten any shoot of the Black Currant at any time, for the wood-buds being generally sparingly scattered, it is better to leave the end one, which is always present. In planting, the Black Currant is usually inserted deeper in the ground than other fruits of its size, and as it is usually furnished with abundance of roots of a fibrous kind its removal is not much check to it. The growth of the first season after planting is looked over and thinned a little, cutting away all horizontal or dependant shoots, as these, when loaded with fruit, hang on the ground and get dirtied. Some care must also be taken that the plant does not hang on one side; this must be remedied by stumping it up with the foot, or when the plant gets large it is cut away on the heavy side, preserving the other to assist in maintaining something like a balance.

Dung, or other manure, must be added in winter, and great care taken not to dig too deep. This practice is really more hurtful to fruit plantations than the digging will compensate for. Even the Black Currant, which is, as we say, planted deep, requires to be carefully dealt with at digging-time, for many useful roots will be found within four inches of the surface, and it is needless here observing that these ought not to be disturbed. It is not uncommon for some growers to heap the earth up in a mound around the collar of each plant, which materially steadies it against the wind and other casualties; and when the ground is light it may be of service, but in a general way it may be dispensed with, and the ground cultivated plain, observing that in all winter prunings to preserve a few young shoots from the centre of the plant, so as to keep up the succession, and not allow it to become too tall, and "run away," as it is called; otherwise, with the exception of these shoots coming forward, the tree ought not, by any means, to be too thick, so that when it has got to what may be called "full size," a considerable quantity of shoots may be cut away every year; cutting away, first, all those which disfigure the tree by their improper length or awkward growth; afterwards, if it be necessary, a few that may be wanted to relieve the tree of its superfluity. However, as all depends on the eye and taste of the operator, it is needless saying more than again pointing out that the summer shoots of the past year ought never to be shortened, but that in all other respects he may cut the tree in any manner with impunity, for it will endure a great deal of ill-usage before it finally gives in. But as a nice plantation of healthy young trees, vigorous, well-shaped, and uniform, is always a pleasing object, I advise the youthful cultivator not to rest satisfied with anything short of excellence in this respect; and though the Black Currant is often thrust into any out-of-the-way corner, yet it is only when they are well grown and orderly-looking trees that they approach the point which it is desirable to attain in an amateur garden; for even in this utilitarian age, the appearance of a tree is not altogether unimportant, especially when planted in a position where it is seen daily, or nearly so. All these points must, therefore, be attended to, and the Black Currant, when grown as it ought to be, will form as useful a fruit as any which grace our tables.

In conclusion, I may observe, that the old variety is still mostly grown; for though the larger one, called the *Black Naples*, has been tried by some of the more spirited growers, it has not become so much a favourite as it was expected to be, for it appears the ripened berries drop off even more than the old kind with the least wind or rain. If this drawback could be overcome by some improved variety of equal size, a desideratum would be attained useful to all, and we have no doubt but attention skilfully directed that way would accomplish this; the same as many other wayward propensities in fruits and vegetables have been overcome. But while the energies of our fruit-growers are all directed to the improved culture or perfection of some more fashionable fruits, this may be neglected; yet there is none more worthy the attention of the enterprising improver, and we have no doubt but a really better variety than those now in existence would meet the reward due to it, as much as if it were a like improvement on Black Hambro' Grapes, or the latest fashionable Strawberry.—H. B.

SHANGHAE FOWLS.

In your last number's notices to correspondents, I perceived you say, that you are "at a loss to see what improvement is conferred by the Falcon Hock" (in reference, I presume, to Shanghae fowls).

As "a curve is a hue of beauty," an artist would, probably, on seeing specimens, one possessing, and the other wanting, this property, decide that the soft, curved feathers curling round and concealing the angularity of the hock was an evident improvement. Whether this is a sufficient reason for the "fashion" setting so distinctly in this direction, is not for me to say; nor is "fashion" much governed by reason; but it is well known to such of your readers as have opportunities of attending poultry sales, that the public taste is so decided in this point, that birds

possessing it have realised considerable sums, which, otherwise, were so inferior, that they would infallibly have been consigned to your "class for dead poultry;" and I have no doubt that in another season it will be considered essential for prize birds to possess this property. In another page, you also express a hope that you may not again hear of such large sums, as have, in a few instances, been given for fowls. I should imagine, that so long as it is difficult to produce them combining ALL the required points of excellence, such as do come up to that standard will command as high prices, relatively to their intrinsic value, as choice specimens of any other description of stock (useful or ornamental) are known to do; and the withholding the first prize for Buff Shanghaes, at the late Birmingham Show, affords pretty good evidence, that in that variety first class birds are not yet very numerous, and that the owners of such are not likely to be tempted to part with them at an ordinary price.—H. W. COLLINSON, 47, *Castle-street, Southwark.*

[The gentleman who wrote the comment upon the Falcon hock is a good judge, but probably meant no more, than that such circumstances are of minor consideration. However, it is a matter of taste only. With regard to our hope that we shall hear no more of enormously large sums being given for a single bird, we only intended to convey the expression of our sincere wish that good birds may so abound as to preclude such high prices being obtainable. In other words, that the supply of excellence will more than equal the demand.—E. D. C. G.]

SEA WEEDS.

(Continued from page 288.)

SOME of my readers may not have seen an account of the gathering of Sea Weeds for manure, coal, and fire-wood, in a History of the Channel Islands, by Inglis; and to them it can scarcely fail to be interesting, as it is peculiar to those islands.

"This Sea Weed is called in French *varech*, and in Jersey dialect 'vraic;' and a busy time is the vraicking season in Jersey. This season is fixed by the island legislature, and is named twice a year, commencing generally about the 10th of March and the 20th of July, and continuing each time about ten days. I have spoken of the beds of rocks that surround the island; and it is chiefly from these rocks and islets that the vraic is gathered.

"When the vraicking season begins, those whose families are not numerous enough to collect the needful supply assist each other; and the vraicking parties, consisting of eight, ten, or twelve persons, sally forth betimes, from all parts of the island, to their necessary, laborious, but apparently cheerful work. Although a time of labour, it is also a season of merriment; 'vraicking cakes,' made of flour, milk, and sugar, are plentifully partaken of, and on the cart which accompanies the party to the sea-beach is generally slung a little cask of something to drink, and a suitable supply of eatables. Every individual is provided with a small scythe, to cut the weed from the rocks, and with strong leg and foot gear. The carts proceed as far as the tide will allow them, and boats, containing four or six persons, carry the vraickers to those more distant rocks which are unapproachable in any other way. It is truly a busy and a curious scene. During this season, at half-tide or low-water, multitudes of carts and horses, boats and vraickers, cover the beach, the rocks, and the water; and so anxious are the people to make the most of their limited time, that I have often seen horses swimming, and carts floating, so unwilling are the vraickers to be driven from their spoil by the inexorable tide. But this Sea Weed is not employed solely as manure, it is also used as fuel, and for this purpose it is collected at other times than at the regular vraicking seasons—not from the rocks, indeed, but from the sea-beach. The collection of this Sea Weed is a constant employment with those who live near the sea shore, and the produce of their labour is either used for fuel, or is sold to those who want it. At almost all times, men, women, and children, but chiefly the two latter, are to be seen at this employment, gathering or

spreading the weed out to dry. They use a rake, or three-pronged pitchfork, and a wheelbarrow, in which it is carried above high-water mark to be dried. This is the universal fuel of the country; and it makes a hot, if not a cheerful fire. Coal is scarcely used at all, and only a very small quantity of wood along with the *vraic*, and this even not universally. On feast days, only, and family gatherings, a coal fire is lighted in the best parlour."

ORDER 9.—CORALLINACEÆ.

"Rigid, articulated, or crustaceous, mostly calcareous Sea Weeds, purple when recent, fading on exposure to milk-white, composed of closely-packed elongated cells or filaments, in which carbonate of lime is deposited in an organised form."—*Harvey*.

Formerly these algae were thought to be zoophytes, but there is now no doubt that they are vegetables. This may be ascertained in a powerful acid, when the lime will be removed, and the vegetable substance be disclosed.

1. *CORALLINA OFFICINALIS* (Commercial).—Very common on all our shores, from two to six inches high, fringing the edges of tide pools, where it affords a snug lurking-place for young crabs, &c.

2. *C. ELONGATA* (Lengthened).—"The lateral shoots of the branches slender and subulate, with long cylindrical articulations."—*Johnst.*

3. *C. SQUAMATA* (Scaly).—On rocks in the south of England.

2. JANIA.

"Frond slender, branched in a dichotomous manner, the joints cylindrical, the crust calcareous unporous, the axis subcartilaginous, solid, constructed at intervals corresponding to the articulations of the crust. Capsular swellings produced in the axis of the branches containing granules. Name from *Jania*, one of the Nereides."—*Johnston*.

1. *JANIA RUBENS* (Ruddy).—Parasitical on small marine plants; common, very bushy indeed, and tufted. Some specimens which I have from *Jaifa* are so thickly clustered that they look like a little dog's paw.

2. *J. CORNICULATA* (Small-horned).—Like *J. rubens*, forming thick tufts, but the articulations of the branches are different. Sub-order, 2. Nulliporææ. Frond crustaceous, or foliaceous, opaque, not articulated.

3. MELOBESIA.

"Name from one of the sea nymphs of Hesiod."

1. *M. POLYMORPHA* (Various-formed).—"Frond attached to rocks, thick, stony, encrusting, or rising into short clumsy branches."—*Harvey*.

2. *M. CALCAREA* (Chalky).—"On many parts of the coast this plant forms vast beds, extending for miles in submarine strata, and is advantageously used as manure on soils requiring the addition of lime."—*Harvey*.

3. *M. FASCICULATA* (Brindled).—"At the bottom of the sea."

4. *M. AGARICIFORMIS* (Mushroom-shaped).—"Frond unattached, globular, hollow. On the bottom of quiet bays."—*Harvey*.

5. *M. LICHENOIDES* (Lichen-like).—Of a pale colour, and, as its name denotes, resembling a Lichen. There are several minute species, of which I shall only give the names.

M. MEMBRANACEA (Skinny).

M. FARINOSA (Floury).

M. VERRUCATA (Warted).

M. PUSTULATA (Pimpled).

Professor Harvey says that the question still remains, whether *Melobesia* are independent vegetables, or whether they be merely amorphous states of the common *Corallina officinalis*. This latter is the view advocated by Dr. Johnston.

4. HILDENBRANDTIA.

1. *HILDENBRANDTIA RUBRA* (Red).—"On smooth stones and pebbles between tide marks, and in deep water. Colour variable—now a bright, now a dull red."—*Harvey*.

"The corallines are found in all parts of the ocean, but are much more numerous in warm than in cold countries, and some of the species of the tropical and sub-tropical ocean are among the most beautiful of marine vegetables."—*Harvey*.

DISEASES OF POULTRY.

BUMBLE FEET IN DORKINGS.

HAVING had recently occasion to kill some Dorkings affected with this disease, I took the opportunity of submitting the feet to careful microscopical examination (with the aid of a gentleman well known for his researches in minute pathological anatomy). As the result of our examination of the disease, in various stages, I may state, that it appears to take its rise in the true skin (viz., the cutis), which is exceedingly thick under the sole of the foot: the first symptom of its occurrence is the presence of a small warty tumour, which appears externally; this gradually extends, and a deep-seated enlargement appears; at the same time, the latter continues to increase, and when it attains a considerable size ulceration takes place, and the scurf skin (or cuticle) covering it is loosened; at the same time a peculiar and offensive odour results from the ulceration of the tumour. It is hardly necessary to remark that the bird becomes lame, and, if one side is affected, rests the foot as much as possible.

On examining the substance of the tumour under the microscope, it was found to be totally destitute of blood-vessels and nerves, and to be, in fact, a mass of dead inorganicized matter, situated between the true skin and the tendinous parts of the foot.

The remedy that would naturally suggest itself for this examination would be the removal of the diseased growth; but I have found, on attempting this operation subsequently, that there are two serious objections to this practice—cutting into the skin around the diseased growth is attended with great loss of blood, the flow of which is checked with difficulty; and the removal of the tumour cannot be effected without exposing to so great a degree the tendinous structures of the foot, that a recovery can scarcely be expected, especially as there is a low stage of vitality in these parts very unfavourable to recovery after injury.

This examination confirms my previous views of the cause of this troublesome complaint, namely, that it is produced by pressure and concussion. Cocks, therefore, are more subject to it than hens from their greater weight; and birds that roost on high, narrow perches, are much more liable to the disease than those than are obliged to rest on broad and low ones.

Another evil arising from high perches for heavy birds is, that they frequently break the keel of the breast bone by the violence with which they descend on to the ground. I killed a Dorking hen, a short time since, in which the breast bone was extensively fractured in this way; and another was under my care, in which I had to remove a large portion of dead bone that had been destroyed in this manner; and I think it very probable that the violence of the shock may severely injure some of the more important internal organs, especially during such time as the hens are laying.

In conclusion, I can, from practice as well as theory, re-

commend low, broad perches as the best preventive of this affection. It is a fortunate circumstance that its frequent occurrence is so easily prevented, when its incurable nature is taken into consideration. In fact, so slightly do I think it is under the influence of remedies, that I would not give five shillings for the best Dorking that ever walked on two feet if one of them was thus affected.—W. R. TEGELMEIER. *Willesden, near London.*

BEE-KEEPING FOR COTTAGERS.

(Continued from page 272.)

Coverings and Shades.—For coverings, nothing better than common glazed milk-pans, or lids of large brown pans: the latter are to be preferred, as having a handle, being glazed on the outside, and throwing off the rain more easily. They make a neat finish to the hives; by their weight they keep the hives steady; and the cost of them, in most localities, is very trifling. They should be sufficiently large to throw the wet well over the floor-board. Where slate or freestone abound, a substitute for them might be made, by procuring a lump of the required size, flat on one side, chipping away the upper surface to give it the form of a sugar-loaf, and just sufficient of the under surface to make it slightly hollow, and so prevent the wet from creeping up towards the hives: this, if of stone, would require painting. Whatever way be used for coverings, it is necessary that the bodies of the hives should also be protected, for on this (as already stated in section 1,) success, in a great measure, depends; for where the hives are exposed to the sun, the bees, by its heat, are inconvenienced in the summer, and rendered unnecessarily active, and consequently hungry in the winter, so that loss occurs all the year round. The protection cannot, perhaps, be better afforded, than by using a thick straw hackle placed over the milk-pan, worked on a hoop of such a size as to fit upon its (the milk-pan's) edge. By leaving the straw of this hackle long enough to reach nearly to the floor-board an effectual shade is made. We have used, with success, a kind of round jacket made of zinc, standing upon the floor-board, and covered by the milk-pans. A few holes at the top edge of the jacket let out all the hot air, the place of which is supplied from the entrance to it, which is made about eight inches broad, and six high, and is covered by a projecting piece which keeps the alighting board, by the hive entrance, quite dry. This jacket may be made of oil-cloth, stiffened by ribs of wood. Where milk-pans cannot be procured, hackles, such as those described, if properly secured against the wind, are the best substitutes.

Adapting Boards.—Several of these will be required; one, at the least, for each hive, and each top hive: they may be made of pieces of $\frac{1}{2}$ -inch mahogany, or pine, some of the same diameter as the stock, others of the same diameter as the top hives, each having a four-inch circular hole in the centre.

Water Pans.—Where brooks or ponds are not plentiful, water must be given to the bees in the summer months. It may be given in any brown shallow pan or trough, filled with good sized pebbles and moss, which will act as standing places for the bees. The water must be changed every day or two. Care must be taken not to cover over the tops of the pebbles, or they will be useless to the bees. Instead of using stones and moss, a kind of raft may be made by tying or nailing strips of light wood each about one inch broad, and an inch shorter than the breadth of the pan, at inch distances along two other pieces of wood, each about an inch shorter than the length of the pan: this raft should be well painted, or the wood will become saturated and sink: an adaptation of this raft may be used as a float for the feeder to be next described.

Weighing Machine.—We fear that it will be out of the power of many of our readers to get this: if so, they must rely upon their hands and judgment in ascertaining the weights of their several hives, taking care to under-estimate rather than over-estimate; after a little practice, very considerable accuracy of judgment may be acquired: experiments in weighing might be made at first with hives filled and partially filled with sand, which might be afterwards weighed in the ordinary domestic scales.

If a spring-balance of any kind can be bought, or even borrowed, then a tall tripod, with stout poles, about seven feet long for legs (like a gigantic milking-stool in form,) may be made, broad enough at the base to allow of its being placed over the hives, and having a piece of tough wood, about six inches square, nailed at the bottom of each leg, to prevent them sinking into the ground. Under the top piece (which corresponds with the seat of the milking-stool, and should be about nine inches square, and three or four inches thick) should be hung a pulley, or, even better, a set of pulleys, and to this pulley, or to the lower of the set of pulleys, should be hung the spring-balance. Four eyes must be screwed into the edge of each floor-board, at equal distance from each other, and two pieces of stout cord, each from four to five feet in length, with a hook firmly fastened to each end of each piece must be provided, and each of these pieces must be run through the ring in the moveable part of the balance. The method of using this apparatus is pretty obvious, will be detailed in section 4. We are indebted to the "Country Curate," for this idea of a tripod; though his is much more neatly and tastily made than that here described, which, however, it is believed, will be found equally useful with his.

Feeders.—As all food must be given at the top of the hive, and in large quantities when given in the autumn, large feeders are necessary. The simplest way to make them is to take a piece of wood, about eight inches square, and half-an-inch thick, and a strip of tin or zinc, equal in length to the four sides of the wood, and about four inches deep; then get one of the round German lucifer match-boxes, cut off the bottom of it, and make a hole about three inches from the edge of the eight-inch square piece of wood, just large enough to fit the part on which the lid of the lucifer-box would shut; fit this firmly into the hole, and you have a tube, up which, when placed over the centre hole of the hive, the bees can ascend. Nail a strip of zinc all round the piece of wood, take it to the tinman, and get him to solder up the fourth side. You will then have a box with a pipe standing up in it, three inches from one side, five inches from the other; counting from the centre of the pipe. Two inches from the side on which you have the five-inch space, have fixed another bit of tin or zinc running all across the box, and to within an eighth-of-an-inch of its bottom; next procure a piece of thin cork as large as the division of the box in which is the pipe; if a piece so large is not to be procured, stitch several smaller pieces together, cut a hole in the centre of it just large enough to fall easily over the pipe, bore it full of small holes with an awl, and burn these holes clean with a red hot iron wire, and you will have a float; paint the box and the float well inside and out, taking care not to stop up the holes in the float; get a piece of thin glass rather larger than the box, and you will have a feeder as complete and handy as any that can be made, and capable of holding four or five pounds of food. To use it, place it over the centre hole in the hive, with the narrow division towards the back of the hive, slip the piece of glass forward, and pour in the food, it will pass under the division, and raise the float.

(To be continued.)

TO CORRESPONDENTS.

** We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of The Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

COCUIN-CHINA FOWLS (R. P., Elmstead).—See what is said to-day about their merits editorially. Some of the sisters of the Dorking-breasted cock there mentioned, and some of the produce of the imported hen, will be sold at Mr. Stevens's Auction Rooms on the 24th instant.

W. ADAMS.—The Authoress of "My Flowers" offers her grateful thanks, and those of the recipients of the Christmas donation, to "C." She has presumed to use her own judgment in one case, and trusts for forgiveness. The "Widow Indeed" is so liberally provided for, that the half-crown meant for her was added to that of the "Poor Widow," whose eyes rained tears of gratitude for the blessing, for the season was very cold and trying. May an hundredfold be returned into that bosom which so kindly remembers the poor.

GUANO (Homo).—R. Errington begs to inform this inquirer, that the party he alluded to uses about two hundredweight to the statute acre of

ghano. He applies it broadcast over the butts, or bouts, as they are called in Cheshire, just before they are soiled over, and the sprouts just breaking ground. The soiling is then immediately applied about four inches in thickness. *Homo* would do well to use two-and-a-half hundredweight, in his case, of real Peruvian, digging his ground well in the end of March, when dry, and setting well-kept seed, *already begun to sprout by design*, immediately on the heels of the digging.

FRUITS FOR YORKSHIRE (B. L., Hull).—Pears—Shobden Court, Gratiosi of Jersey, Broom Park, Haco's Incomparable, Thompson's, Forelle. Dessert Apples—Kerry Pippin, Court of Wick, Golden Reinette, Nonpareil Pitmaston Russet, Wyken Pippin, Boston Russet, Old Nonpareil. Kitchen Apples.—Wormsley Pippin, Beauty of Kent, Winter Majein, Gooseberry Apple, Alfreston, Calville Blanche. This selection is an admirable one, and just such as we would have recommended to you. Of PEARS for the east wall, you should have *Jersey Gratiosi, Haco's Incomparable, and Forelle.* Of APPLES, *Golden Reinette, Pitmaston Nonpareil, Russet, and Old Nonpareil.* All the dessert Apples in your list may be grown on Paradise stocks with success; but the culinary varieties should be on the Crab. The whole of the Pears will do on the Quince; but unless your soil is heavy and wet, we would not advise you to adopt it as a stock.—H.

RICHMOND VILLA BLACK HAMBO' GRAPE (J. B.).—We know this Grape, and, from what we have seen of it, it appeared to us to be very like a variety which we have known for the last six or seven years by the name of *Black Champion.* We are not prepared to say that it is the same, but if it is so similar as it appeared to us to be, it is a very first-rate Grape, and well worth cultivating even in the smallest collections. It is very superior, both in the size of the berry and bunch, to *Black Hambro'*, is nearly a fortnight earlier, produces berries of a more uniform size, and colours better. Such is our opinion of *Black Champion*, and such, also, was the opinion we formed of the *Richmond Villa* when we saw it. But we are always delicate about giving decided opinions on new things until we have had sufficient experience of them. We must, therefore, leave you to act in some measure on your own responsibility.—H.

FLOWER-GARDEN PLAN, No. 11 (J. Yorkshireman).—That plan would do for even a smaller place than yours. The circles can be about five feet in diameter, and you ought to allow three feet between the beds; but the right way to go to work would be to get out the garden line, and a good bundle of little sticks, and with them to try to make the actual figures from the plan; then, if you found the place too small, allow less distance between the beds rather than curtail them.

ROSES (Rev. P.).—We have often said that all the strong hybrid China Roses, like *Blairii, No. 2*, will not, or rather will never, flower well, if at all, provided they are pruned like Moss and Cabbage Roses. Printed lists of these, and all other Roses, are offered for the mere charge of postage by all the great rose-growers, therefore it would be only waste of paper for us to print such lists.

GOOSEBERRIES (Ibid.).—The following are among the best table Gooseberries; the first three are small, and the other three large kinds:—Rough Red, Red Champagne, and Pitmaston Green Gage; Boaring Lion, Red Warrington, and Rifleman. For baking—Dixon's Golden Yellow, Wellington's Glory, British Crown, Keen's Seedling, Heart of Oak, and Jolly Angler, are as good as any, but there is a score as good as these, and if you send to Mr. T., who knows more of this class of fruit than any gardener, he may give you even a better selection; he is still where you say, and is a trustworthy dealer.

FLOWER GARDEN (Jonathan).—Your plan will be engraved, when your questions will be answered, with some observations of our own. It is a very useful plan for many places.

FRONT GARDEN (F. W.).—The usual way of screening off the house from the public road is by planting a hedge of common Laurels, as from gate to gate in your plan, the plants to be about four or five feet high, and to be planted a yard apart along the boundary, and two feet from it; that would be by far the most convenient way for you, then the whole border in front of the hedge would be at your service for a selection of such things as you like best. If you plant all with them, you will have no flower to speak of after June. Why not use perpetual Roses one-half, and such shrubs as Ribes sanguineum, Pyrus japonica, Philadelphus Gordonianus, which flowers in July, Dwarf Almond, Red Mezereum, Yellow and Silver Variegated Hollies, Evergreen Barbery (*Berberis aquifolium*), Darwin's Barbery, Forsythia viridissima, Dentzia gracilis, Leicostera formosa, Sweet Briar, with common and Tree Peony, Lupinus polyphyllus, Phloxes, and a few Scarlet Geraniums in front.

OXALIS BOWII (Constant Reader).—The enclosed fleshy tuber-like thing is what we have all along called *fangs*. A section of the Oxalis genus make these fangs to convey nourishment to a new colony of bulbs, which settle at as far a distance from the old bulb as the farthest ends of such fangs, exactly as the "runner" from a Strawberry plant is meant to extend the young from the old plants. The Oxalis, by means of these fangs, year by year, would soon bury its new made bulbs in loose soil so deep that they would never flower. Your bulbs are quite right and proper; leave them as they are till next April, but not quite dry; by that time the substance of the fangs will be expanded in making a set of new bulbs for you.

TACSONIA MOLISSIMA (E. M.).—Your question has been answered in our articles on the genus. Your plant flowered in a greenhouse, and fruited also. You pruned it back to the main stem, and you are afraid there will be no room for it, which is all quite right, unless your house is a Crystal Palace, for this is the first climber we would plant in the new Palace at Sydenham. In three years it would reach up to the highest part of the centre transept. To get your plant under control, you must cut off so many of the roots every year, just as is recommended at page 105 of this vol.; and, besides that, a large portion of the annual growth ought to be trained outside the house, as there stated, in a good border. No ordinary greenhouse is large enough for the three Tacsonias, except for a few years. Get *manicata* and *pinnatisipula*, and inarch their young shoots into young shoots of *molissima*, then humour the three on the

same roots, and try and leave *pinnatisipula* outside every season. The other two "time about," that is one of them outside one year, and inside the next. The roots, the roots, the roots, of these Tacsonias are the things to manage, and to cut off every bit of young wood every year except the main leader, or leaders, but the more you cut them, without cutting the roots, the more they will not flower.

CLETHRA ARDREA (Ibid.).—We should have no fears about it in that part of Dorsetshire against a south wall, but we would mat it the first two or three winters—it is about as hardy as the "Green Wattle,"—*Acacia ulmifolia*, alias *dealbata*. It is very doubtful if the Tacsonias, or *Tecoma jasminoides*, would stand out there without good covering; but as you have plants of them, why not try them, and let us know. "A faint heart never won a fair lady," or proved half so many Gordon experiments, as the heart of spades.

CLOTTED CREAM (Ibid.).—That is the Devonshire fashion, and we know of no better way than working it by hand. A clergyman near us gets all the butter from three or four cows done "by hand," and prefers it to any other way. The new milk is scalded by plunging tin-pails of it in a copper of boiling water; the cream is managed in the usual way, and the butter is made by working up the cream in an open wooden tub by the hand, just as they work the yolk of an egg with a spoon.

WOODEN SHUTTERS.—"J. T. L." says, page 250, that he cannot get them six-feet-and-a-half by four under 10s. I have had some made after Mr. Fish's recommendation, three-quarters-of-an-inch thick, planed on one side, joined well together, fastened to three cross pieces, and a ledge round. My size is not quite so large as "J. T. L.'s;" his size could be made by my carpenter for 6s. 6d. each, cash. His address is R. Allen, Mile End, near Whittington, Salop.—J. P. O.

Cow (q).—We cannot discuss such a subject in our pages.

AURICULAS, &c. (Bertha).—All the plants you mention can be raised from seed; but as you can buy them all very cheap, and you would have to wait a year or two for seedlings blooming, we advise you to buy plants.

SAND FOR POTTING (A Devonshire Rectur).—The fine shell sand of which you enclosed a sample would answer very well for potting purposes. Even the granite sand from Dartmouth, if the black sediment was washed out from it, would also do very well.

MANURES (K.).—As you have no stable-manure you must use guano, ground bones, urate of the London Manure Company, super-phosphate of lime, &c. These will do for Turnips, or any other crop; super-phosphate and urate would, probably, answer your purpose. If you live near the sea, sea-weed will be a good store for you. Save all weeds, scourings of ditches, and any other vegetable refuse, in a pit, and have the house-slops emptied over them.

ICEBERGS (L.).—You will have seen what Mr. Beaton had written before your note arrived.

DYEING EVERLASTING FLOWERS.—A subscriber will be much obliged by information how to dye Xeranthemums, &c.

HARTLEY'S ROUGH PLATE GLASS (M. S.).—It is perfectly suitable for ainery.

POULTRY DISEASES (W. Southcote).—You must advertise your capabilities. It is quite impossible we can recommend that or those totally unknown to us.

AUSTRALIAN LAUGHING PIGEONS.—A *Pigeon Fancier* wishes for a description of these.

HEN LAYING WHILEST ROOSTING (E. F. S.).—Nothing is so easy to cure as this. Let her sleep in a place where there is no roost, and where she must consequently sleep upon the ground.

CANCER.—If "H. B." will send an address to the Editor, a private communication might be had from the party.

POTATOES WITHOUT MANURE (A. B.).—If your soil is fresh, and has been well trenched, you may apply thirty bushels of soot and thirty bushels of salt per acre, and be certain of a better crop than if you manured with stable-dung.

SHREWSBURY SHOW (S. D.).—It shall appear next week. If Secretaries of such Societies as advertise in our pages will oblige us by sending reports of the exhibitions we shall always insert them most readily. It is quite impossible for us to send special reporters to all.

MOTHERLESS CHICKENS (W. L. S.).—Feed them upon eggs boiled hard, and chopped fine, mixed with bread crumbs and a little barley meal or Indian meal. They only require this for the first fortnight. A little crushed hempseed, given once daily, mixed with their other food, is very beneficial.

NEST EGGS (A Subscriber).—Any turner of wood could make wooden ones for you.

DENDRONIUM (A Gardener, Liverpool).—No such specimen reached us; send us another. We answer all queries without the slightest preference.

SPANISH COCKEREL (W. Curtis).—Send an advertisement.

NAMES OF PLANTS (Ignarus).—No. 1. *Aspidium filixmas.* No. 2. *Aspidium dilatatum.*

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kalend; and Published by WILLIAM SOMERVILLE ORR, of Church Hill, Walthamstow, in the County of Essex, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—January 19th, 1854.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 44.7° and 32° respectively. The greatest heat, 67°, occurred on the 26th in 1834; and the lowest cold, 16°, on the 26th in 1827. During the period 101 days were fine, and on 88 rain fell.

NEW PLANTS.

DIDYMOCARPUS HUMBERTIANA (*Humboldt's Didymocarp*, or *Twin-fruit*).

This genus is closely allied to *Streptocarpus* and *Chirita*, and the species before us so closely resembles *Chirita sinensis* in habit, that it not improbably will be added to that genus. It is not the same as *D. primulifolia*, if the description of the latter be correct, which assigns to it a downy stem, and no radical-leaves, for *D. Humboldtiana* has no stem, and radical-leaves only. It is a native of the mountain districts of Ceylon, at an elevation of about 5,000 feet. It belongs to the Natural Order of *Gesneriacerts*, and to *Didymamia Angiospermia* of Linnaeus. The flowers are usually pale purple, but sometimes white, and open here during October in a warm greenhouse.—(*Botanical Magazine*, t. 4757.)

ERYTHROCHITON BRASILIENSE (*Brazilian Red-Tunic*, or *Erythrochiton*).

The name of the genus refers to the red calyx, and that of the present species to its native country, whence it came in 1842. It has a palm-like, branchless stem. The flowers are white, large, handsome, and come in succession through many months of the year. These qualities render it a very desirable ornament of our stoves. It belongs to the Natural Order of *Rueworts*, and to *Pentandria Monogynia* of Linnaeus.—(*Botanical Magazine*, t. 4742.)

SCHLERIA MEXICANA (*Mexican Schœeria*).

It so closely resembles *Achimenes* that it is very frequently known as *A. Schœerii*. There are two kinds, the purple and the blue-flowered, but which is the species, and which is the variety, is undetermined. It is a native of Chihuahua, one of the northern states of Mexico, whence it was received in 1850, by F. Scheer, Esq. It bloomed at Kew, in the autumn of 1852, and Sir W. Hooker says—"We have no hesitation in predicting that in a few years it will be found in every garden." (*Botanical Magazine*, t. 4743.) It is a *Gesnerwort*, and belongs to *Didymamia Angiospermia* of Linnaeus.

BERBERIS CONCINNA (*Neat Berberry*).

This is a very agreeable addition to our list of evergreen Berberries, and the more so from its dwarf habit. "It is allied to the *B. Sibirica*, also a single-flowered plant, but readily distinguished by the long tripartite spines, slender pedicels, and glaucous leaves; the latter, however constant a character in both our wild and cultivated specimens, is not a constant one in other species of the genus, and hence may prove variable in this. The seeds were gathered from small bushes growing in the Lachen valley of the Sikkim-Himalaya, at an elevation of 12,000 to 13,000 feet; it there formed a small low bush, one to three feet high, with spreading almost prostrate branches, thickly covered with small leaves of a deep green hue; and polished above, snowy-white and glaucous below; these colours, the large oblong scarlet berries, and red branchlets giving the shrub a singularly neat and pretty appearance when in fruit. The specimens in the Royal Gardens at Kew have come up perfectly resembling wild ones, and flourish luxuriantly in an open border."—(*Botanical Magazine*, t. 4744.)

HELIANTHUS INSIGNIS (*Showy Blood-Flower*).

This bulbous-rooted plant is a native of Natal. It flowered during the August of 1853, at Kew, in a cool frame. It belongs to the Natural Order *Amaryllids* and *Hexandria Monogynia* of Linnaeus. Flowers in large umbels, orange and crimson-coloured.—(*Botanical Magazine*, t. 4745.)

For the very valuable monograph of *THE GARDEN PEA AND ITS VARIETIES*, which we now commence, we and our readers are indebted to Mr. Robert Hogg, author of "British Pomology," and other works.

Among the curiosities of garden literature in the present day are the seedmen's catalogues. Of all

shapes and sizes, from the great broadsheet to the bulky pamphlet and the stamped "price current," they are as far in advance of those of the last century as the new edition of the "Encyclopedia Britannica" is of the first. But while they have so increased in volume, and improved in appearance, the question arises—Have they

done so to the same extent in utility? That we should go on from one degree of excellence to another is one thing, and a most desirable end to be attained, but to extend varieties and multiply the names of varieties for the mere gratification of whim or fancy is quite another matter, and leads to nothing but confusion, disappointment, and annoyance.

I have now before me three seed catalogues of the last century, varying in dates from 1780 to 1791, and each issued by separate establishments. The greatest number they can collectively enumerate of Peas is 23; of Brocoli, 5; of Cabbage, 8; and of Lettuce, 13; these I have selected as illustrations, and it will be allowed, that so far as the number of varieties is concerned they are amply sufficient for all purposes. But I have also before me three catalogues of the date 1853, also issued by three separate houses, and in these the collective enumeration of Peas is 88; of Brocoli, 47; of Cabbage, 46; and of Lettuce, 53, varieties! Need it be wondered at, therefore, that the public, and "the trade" themselves, are longing to be freed from such a chaos of names and nonentities. It is exceedingly desirable that we should have new varieties—the more the better. It is only in this way we can expect to improve as we have done during the last few years. Were it not for some step in that direction we might still have been confined to the *Charlton* for the earliest, and the old *Marrows* and *Marotto* for the late; but the time has now arrived when such old varieties as are found to be inferior to those of more recent introduction should be discarded. It is a complaint of daily occurrence that there is such a multiplication of varieties, and names of varieties; and some have ventured to attribute this to unworthy motives on the part of the seedsmen; but, as a body, I know the respectable part of the seed trade deprecate such a state of matters as much as any one, and glad would they be if the public would take the matter in their own hands, and ascertain what is really worth cultivating and what is not; if they would so make themselves acquainted with what they grow, as to be able to decide upon what is distinct and what is not. Much has been said, of late, endeavouring to inculcate the seedsmen. It is not for me to advocate the cause of any party, as I have no interest in the matter beyond a desire to "see things called by their right names," and, if possible, to reduce the number of useless and unnecessary names and varieties. But I believe much of the confusion has arisen with the public themselves: it is with garden vegetables as with fruits. A person becomes possessed of a first-rate variety, of which he has lost the name, or of which, he, perhaps, has never known the name; he is pleased with it, cultivates it, takes prizes with it, and, if of a liberal spirit, distributes it among his friends and neighbours: in course of time it is associated with his own name, is advertised as "a new thing," gains popularity, and "the trade" become possessed of it to enable them to oblige their customers. One-half of the world soon discovers it to be the same as something else, but the other half

will not believe it is so, either because they have not observation enough to see the identity, or because they have never seen that with which it is identical; and so they persist, year after year, to buy, and cultivate, and recommend it under the name by which they first made its acquaintance. And so it is with the Pea, Brocoli, Cabbage, Lettuce, and every other crop; and until the public use a little more discrimination they must continue to dwell in this state of bewilderment, and the seedsmen remain the passive agents of their patrons.

It is for us, therefore, to make ourselves acquainted as much with what we grow as we do with how to grow it; to exercise a little more observation, without taking things for granted, and then we shall have the remedy in our own hands. With this view, I, last season, determined to make myself acquainted as much as possible with the subject, beginning with the Pea and its varieties; and for this end I procured all the varieties of garden Peas which were to be obtained in London, under whatever and as many names as they were to be had, taking care that all new varieties were got from those houses which professed to supply them true and genuine. They were all sown on the same day, and on the same piece of ground, and were carefully noted at least once, but frequently twice a-week. In addition to this, I most kindly and liberally received permission from several of the wholesale London seedsmen to make free use of their sample grounds, in which they make trials of all the seeds they have supplied during the previous season; and it is from observations so made that I am now enabled to furnish some account of the garden Peas. The varieties are arranged in the rotation in which they came into pod.

TAYLOR'S PROLIFIC.

This is a very early Pea, earlier, if anything, than even *Sangster's No. 1*, but is of a more slender habit of growth. The pods are all strictly single, and are of the size and shape of *No. 1*, containing, on an average, from six to seven peas in each. The plant is two feet high, and produces perfect pods even to the top of the haulm, when the whole ripen off simultaneously.

Taylor's Prolific seems to be a very superior variety of the old *Early Kent*, from which it has, no doubt, originated. I obtained it from Messrs. Noble, Cooper, and Bolton, of Fleet Street, who seem to have paid particular attention to the preservation of the true character of this excellent variety. It was sown on the 29th of March, and fully slatted on the 8th of June; but, as regards earliness, it cannot be called more than a day before *No. 1*. It is a very good cropper, well adapted for foreign and early sowing, and in field culture produces, on an average, five quarters per acre.

EARLY KENT.

SYNONYMS.—*Prince Albert, Early May.*

This variety may be included under the same head as

the preceding, but it is very inferior in every respect—the pods being much smaller, fewer in number, and very much less productive. It is, therefore, now unworthy of cultivation.

SANGSTER'S NUMBER ONE.

SYNONYMES.—*Daniel O'Rourke, Waite's Daniel O'Rourke.*

This variety is of a slender habit of growth, more so than *Warner's Emperor*, and consists of a single stem two feet high, producing, on an average, from eight to ten pods on each plant. Pods generally single, but frequently in pairs; ten-inches-and-three-quarters long, and upwards of half-an-inch wide, quite straight, thick, and plump, and terminating abruptly at the point. When fully grown they become much swollen, broad in the back, and somewhat round, or quadrangular. They contain, on an average, seven, but frequently eight, peas. The ripe seed is white.

This, and *Waite's Daniel O'Rourke*, were sown in adjoining rows on the 5th of April, and came into bloom on the 5th of June; on the 9th the first blooms began to drop, and the slats (young pods) appear; by the 22nd the whole plants were nearly out of bloom; and on the 1st of July the pods were quite filled and ready to gather. I have been most particular in my observation

of these two varieties, as it has been said by some that they are distinct. That there should be no mistake, I procured *Sangster's Number One* from MR. SANGSTER, and *Daniel O'Rourke* from MR. WAITE. They were sown on the same day, came up on the same day, slatted on the same day, podded on the same day, and died off on the same day, after having attained the same height, and presented the same habit of growth. I have preserved the original name of *Sangster's No. 1*, because it holds priority of the other, and because I know, by my own personal knowledge, that this variety has been in that gentleman's possession for the last eight years. There are too many varieties already, without increasing them by multiplying the names of those that do exist.

This is a very valuable Pea, and should be cultivated in every garden as the earliest crop. As regards earliness, it does not surpass *Warner's Emperor*; but it possesses the desirable property of doing its work quicker than that variety, and as much so as the *Early Kent*, but possessing a much larger pod, and being more prolific. It is not so tall by some inches as *Emperor*, stops growing and blooming much sooner, and is ripening off when *Emperor* is still fresh and growing. In this respect it is very valuable to the gardener, as it enables him, after obtaining a prolific crop of early Peas, to clear the ground for something else.

WARNER'S EMPEROR.

SYNONYMES.—*Warner's Conqueror, Isherwood's Railway, Morning Star, Rising Sun, Emperor, Conqueror.*

Plant of a slender habit of growth, always with a single stem, which is two-and-a-half to three feet high, and produces from eight to ten pods on each plant. Pods generally single, but frequently in pairs, from two-and-a-half to three inches long, perfectly straight, and terminating abruptly at the end. They are well-filled, and contain from five to seven peas, which are roundish and flattened, seven-twentieths of an inch long, six-twentieths broad, and the same in thickness. The ripe seed is white.

The seed was sown on the 5th of April, and the plants came into bloom on the 5th of June; the blooms began to drop on the 9th, and on the 1st of July the pods were completely filled, and ready to gather.

Too much cannot be said in praise of this as an early variety; but, as remarked under *Sangster's Number One*, it does not get so quickly off the ground as that variety.

R. H.

(To be continued.)

LIKE the *Bourgeois gentilhomme* who discovered that he had been talking prose all his life without knowing it, many of our readers will, ere this, have discovered that they are every day putting in force some of the best means for preventing disease and prolonging life.

If more than 100 or 120 persons cannot dwell together on each acre of ground without the air of the place being sensibly worsened, it is clear that where each house has a garden attached any dangerous amount of over-crowding can hardly take place. The constant demand for manure in a garden, must tend to diminish the standing nuisance from cesspools, sewerage, and so forth. Many of the same laws govern animal and vegetable life, therefore it follows that the healthy or unhealthy condition of ninety-nine out of a hundred garden products is the very best eudiometer or measurer of the salubrity of any situation. Thus, if the whole air be so smoky as to affect the growth of flowers and fruits, it will affect children's lungs also. Smoke or soot (carbon), in descending from the upper air, imbibes and fixes all the exhalations from the bodies and lungs of a dense population below, so long as it is newly burnt, warm and dry, in virtue of a law already explained. But, on becoming cold, damp, and over-charged with ammoniacal matters, the soot at length begins to give out again, in low, moist situations, all the noxious compounds previously imbibed. And, although coarse herbage and some descriptions of trees may

thrive under such stimulants, and great, hearty men, in the prime of life, take no great harm in a smoky atmosphere, yet it makes sad work with children and delicate people, and with delicate plants.

Another great sanitary law is, that inside a house or room each individual requires at least 500 cubic feet of space, or nineteen cubic yards, or a cube of eight feet each way, in height, length, and breadth, to respire in, due regard being had to ventilation. This is known and acted on in such institutions as model prisons and lunatic asylums, but at balls, routs, concerts, lectures, schools, theatres, public meetings, public houses, and other places of public recreation, falsely so called, no regard at all is paid to this simple requirement. Gas-burning greatly adds to the contamination of the air. (During the last visit of cholera, the Edinburgh College of Physicians even cautioned people against crowding to their favourite evening chapels.) A needless sacrifice of life takes place every year among the young, from crowded school-rooms, and insufficient play ground and want of holiday-making. We have noted very many cases of sudden death clearly traceable to the excitement of political meetings—a sort of intoxication far more besetting than that of the accompanying beer barrel. The ancients had a name for this social disease, which, with them, assumed the form of epilepsy.

How few of these evils affect those who live in the country. Children there have room enough to play in; and seed time, hay time, and harvest (according to the reports on education), are always made holiday of. And then (right or wrong) country people leave a great deal to their superiors in political matters, and they live the longer for it. Half-a-century ago, a north-country farmer was asked what he really thought about the state of affairs. "I think, indeed!" he replied; "don't you know that Lord George Cavendish thinks for Furness Fells, and Charles Fox thinks for Lord George Cavendish!" On the contrary, the Americans (according to Lord Carlisle) are all politicians, and always unhappy and unhealthy. The chief danger of crowds to our country people arises from their staying too long for their own good, or that of their cattle, at great markets and fairs. It is a safe rule to "Give a market price, and take a market price, and get home by dinner time."

A very numerous class of sufferers, however, calls loudly for the abolition of the smoke nuisance, and the extended occupation of suburban gardens, with an encouragement of the allotment system, and removal of needless restrictions on the sale of land *in and about towns*.*

* Cato says—The countryman has the fever had thoughts; his property binds him to the state not so much as a pledge, but by stronger and better ties of feeling; and it is natural that a labourer wholesomely exercising the bodily powers, not performed in gloomy dwellings, but in the unrestricted light of nature, in sunshine and storm, should preserve the mind sound, cherishing a sobriety and keenness of observation, a quiet, unbiassed judgment. The freeholder who cultivates his own field enjoys, in the progress of the seasons, and the nature of his employment, an unvarying, a liberal relaxation, without which it is impossible that mind and body can be maintained. The city operative scarcely recruits his strength on the holiday; he allows himself no respite from toil; dependent on those to whom he looks for favour, he feels, or is the object of the jealousy of trade in which one party is ever clashing with another; he wants the calm self-confidence inspired by permanent property. The ideas of the peasant are lively and pleasing, because their number is confined; those of the townsman are confused by obscure conception and misapplied language. In the country the national race is kept up; towns are made up of all nations and lands. [*Niebuhr*.]

New public parks and pleasure grounds for the living are more generally needed than even cemeteries for the dead and hospitals for the sick and dying. In planning suburban residences for working men (where land is comparatively cheap), either open squares should be laid out with garden-plots to the front of the houses, or enclosed, hollow squares, for greater seclusion, with the gardens behind, after the Eastern fashion. All our good things in the shape of free commerce, education, and free institutions will soon be lost to us, unless we give our fellow-countrymen free air, and, above all things, habits of personal cleanliness and purity.*

The signal fall of many great cities has been traced to both moral and physical causes of corruption. All crowded places near the level of the sea are especially prone to all the known forms of epidemic disease, from which, however, an elevation of 100 or 120 feet gives a comparative immunity, and 350 or 400 feet a very great immunity indeed (as Mr. Farr tells us); 350 feet happens to be precisely the height of ancient Jerusalem; though Tyre, Sidon, and all the once proud, and wise, and rich cities of Phœnicia were by the sea shore—Damascus, one of the oldest cities in the world, still numbers 150,000 or 200,000 inhabitants. It stands at an elevation of 2,200 feet. But it is with its beautiful suburban gardens than we have at present to do. According to Col. Chesney [*Tigris and Euphrates*, v. ii]—"The city is embosomed in flower and fruit-gardens, dotted here and there with kiosks shaded with trees; the whole forming a wooded belt of thirty miles (some say fifty miles), at least, in circumference, terminated at one side by an almost boundless wilderness."

A part of the river which waters all these gardens, is here lost in pools and marshes, and, accordingly, no wonder that when the wind sets in from this quarter "intermittent fevers prevail in autumn; yet, on the whole, Damascus must be accounted a healthy city, and in it aged people are very numerous." Now, we have the authority of Mr. Simon, for stating, that in the city of London few people reach to three score years and ten.

J. J.

RENOVATION OF OLD GARDENS.

I HAVE heard it said oftener than once, that the reason why "Uncle Tom's Cabin" was read simultaneously, as it were, all over Europe, was because *The Times* spoke out so strongly against it on its first appearance. I have myself acknowledged, over and over again, that Mr. Cobden gave a great impulse to the circulation of *THE COTTAGE GARDENER* when he proposed his scheme for buying freehold allotments, as I shall call them. Those who aspired to be prime councillors, if not prime ministers, advised their trade associates, all over the country, to do as Mr. Cobden wanted them to do, and

* The cleanness of the body is a symbol of the purity of the soul; external purification is called sanctification, because it makes those observe at least an outward purity who draw near to the sanctuary. Cleanliness is a natural consequence of virtue; since filthiness, for the most part, proceeds only from sloth and carelessness of spirit (and we generally find cleanliness practised in proportion to the prevalence of an spirit of genuine piety). It is certain, the nastiness in which most of our lower sort of people live, especially the poorest, and those that are in towns, either causes or increases many distempers. [*Fleury—Ancient Israelites*].—J. J.

after that to take in THE COTTAGE GARDENER, to see and learn how to manage the new freeholds; so they did; and after draining, trenching, and cropping, on the true Erringtonian system, the new freeholders began to lay siege to these pages for advice about flowers, climbers, pigs and poultry, about ewes and lambs, Swedish turnips, bees and pigeons, till, at last, these freeholds were as full as nuts. After all this we—the staff and standard of the onward progress—thought it would be all plain sailing with us—no more new dodges to think, or write, about; but no, we were then threatened with civil war and open rebellion—first come, first served—fair play loudly called for by the fairest portion of creation and English law, ditto by good judges. I want—and I want—and everybody wanted, just everything except what everybody else wanted not; and, indeed, there were so many interests “wanted” in our pages and in our camp, that we had to *diploamise* as cautiously as if we had been one of “the Four Powers.” Yet, after getting over the “crisis,” here we are again as deep in the mud as ever by the doings of the “Encumbered Estates Commission” in Ireland. Hear what our correspondent, *Curragh Cathol*, says, all the way from Dublin. “We have just taken possession of an old place, to which there was appended, ‘once on a time,’ very fine gardens; at present, there remain fine *garden walls* and the skeleton of once a grand conservatory and vineries. I look forward to a busy and pleasurable spring, hoping to profit by Mr. Errington’s excellent advice in restoring an old (in this case, ruined) garden to some order before many months have elapsed. It would serve and gratify me, and probably many others, if he, or some other of your corps equally capable, would take in hand ‘The renovation of old shrubberies,’ with a list of those good hardy and half-hardy shrubs introduced within the last ten or fifteen years;” and so forth.

Whatever may become of Ireland, one thing is certain of the Irish themselves, they excel all the nations of the earth, when they appeal to the best feelings of our common nature, be they in love, law, or logic, and my young Cedar of Lebanon must stand over, without thriving, for another week or two, as a proof of the assertion to begin with.

Now, for the sake of Old Ireland and all that is Irish, let me entreat of *Curragh Cathol* not to cut down a tree or shrub in this “old place” until he has well considered all the pros and the cons, inside, outside, and all around it. Nothing is easier than to pull down trees; any blockhead can do that. There is a story about a chopping-block, which stood years in the back kitchen of an old Irish mansion, which sprouted at last, and was transplanted, and formed a fine tree after all; but all the blocks chopped upon in Ireland for the last year or two, or for the next half dozen, may not be so excitable, and anyone who will try the experiment, by cutting down trees and setting their blocks or bottoms for chopping on, without well considering what they are about, ought to have their own heads—no matter where.

If I took possession of an old place in Ireland, or elsewhere, the first thing I would do would be to put the kitchen-garden, the vineries, and conservatory, with all the offices, in good, thorough repair. Also the carriage-road, and other roads necessary for more private use. In doing that, I might find that a better line for any such roads might be taken; that, again, might involve some fresh planting in different places; at least, I would settle all that, and get a plan drawn out of all the main improvements before I would fix on what alterations I would make in the old shrubberies and pleasure grounds, as, no doubt, many of the trees and shrubs require to be thinned out, and if they, or any of them, could be transplanted, that would be better than cutting them down. Good planters could remove

very large trees and shrubs if they were properly prepared, say by cutting round their roots at three feet from the stems, all round, this next spring, so as to be ready to move next October. We might gain fifteen or twenty years by this way of going to work, besides having the newly transplanted things more in character with the rest of the place.

After that, I would fix on all the best specimens that could be left in their present position, and put them in proper trim by the knife, saw, or hook, but instead of rooting up all those that were interfering with the best specimens, I would first consider whether any or most of these could come in useful for me before my improvements were finished, and if they would, I should be loth to destroy them, and it is always time enough to throw away things when we are sure we do not want them. Still, I would not allow very common things to interfere any longer with better things; I would cut them down to the ground at once, and I would dig the ground about as deep as possible, or even trench it, and in doing so there would be a good opportunity for cutting in the roots of the cut-down plants, as you would those of herbaceous plants in a mixed border. Very old Lilacs, Syringas, Guelder Roses, Privets, Laurels, and a hundred more such, could thus be renewed in one season, so as to make a respectable appearance, and to be ten years in advance of similar kinds brought in from the nurseries, and they would easily remove and come in useful somewhere else, after one or two season’s growth where they now stand. There is hardly an old shrub in the country, evergreen or otherwise, which might not be improved, in some way or other, so as to be of as much interest, or even novelty, as any of the more recent introductions.

Bear in mind what I have said, long since, about making standards and half-standards of Laurels, both common and Portugal, Privets, Alaternus, Phyllerias, Sweet Bay, as well as of every one of our common shrubs, and there never was a better opportunity for making them than when an old shrubbery is to be thinned or condemned. Every old shrub that is cut down to the surface of the ground, be it worn out ever so much, will throw up one or more strong shoots the first season, and if you confine the growth to the strongest shoot, there is a standard for you at once, if you help it on by summer pruning; and then, if you only remove suckers from it when you come to transplant it into fresh soil, you have, perchance, the work of six or ten years all ready in one season, and spare you no end of money, besides setting you up with such plants as are thought, now-a-days, very fashionable. A few years since, I made a nice standard of an old stool of the Fly or French Honeysuckle on this plan, and I recollect that a duke’s gardener, and one from a noble lord’s place, both were puzzled the same week, to know what it could be; and others thought it to be the *Weigelia rosea*, because it stood in one of the best situations about the garden, but no one looked at it, or if they did, thought very little of it, all the years it stood straggling among other shrubs. A standard of the snow-ball Guelder Rose is as pretty a plant as the newest from California, and an old stool of it, cut down this spring, will make a stem as clean as a ramrod, and as tall as any man, in one summer. Many of the common Spiræas make the prettiest little standard plants you ever saw, and so with all the rest of the very oldest shrubs; and I can tell, from my own experience, that great people, now-a-days, think a great deal of this style of plants, but we are not tied to standards for all that; and if we like bush plants better, the old shrubbery will furnish them as fresh and much stronger than the purse, if we mind what we are about. At all events, I do not advise any one to cast off old plants merely for being old, and only requiring a little management

to make them young enough, and of any shape required.

To give another turn to the question for and against an old worn-out or choked-up shrubbery, and suppose that any of us, wishing for a fresh start, sent an order to a first-rate nursery for an assortment of all the new shrubs and low trees that have been introduced for so many years past, with only this one restriction, that none of these should be sent us for which more than a guinea is charged, but of those under half-a-crown a-piece send six of this, ten of that, and fifty of the other, and so on. Now, where could all these be better provided for than in this very old shrubbery, after all the old shrubs are rooted out, and leaves and their ashes spread over the ground, which is then trenched three spits deep, taking up six inches of the very bottom to be mixed with the best soil in the trench on the surface; surely the young stock will take to this deep wrought soil at once, and we may plant them now so thick as that in two or three years two-thirds of them may be removed to other places, which is all quite true; but still I hold to my first time. There are so many irons in the fire when one begins a new place, or to improve an old one, that some must go to the wall, or come off second best; and if we made up our minds to do away with every plant in the old shrubbery, except some very fine specimens, and that the whole ground is to be renewed at once by deep trenching, as above, there is a cheaper, more safe, and much better way of managing the young plants from the nursery than that of planting them at once on the site of the old ones.

The moment I made up my mind about the number of new plants that I could afford to buy and pay for in one year, I would order them at once, and I would plant them in nursery rows, in a new-trenched piece of ground in the old kitchen-garden, where they would be ready for my hand at any time when I was ready for them; but I would not consider it as just ready for planting when the site of the old shrubbery was trenched, because such ground is sure to settle down uneven. Root weeds are not all taken out at once, there will be roots, or bits of suckers from the old plants, that you cannot get rid of till they show where they are by next growing season; and besides, the shrubbery ground is yet too much exhausted by the old roots to furnish the necessary supply to a fresh crop of similar quality, which is the greatest objection of all. These objections could only be got over by allowing the newly trenched ground to lie for a season under some cleaning crop, that is, a crop which would allow of the ground to be worked or stirred between the rows or plants; and when this crop was removed, the whole ground would be dug over and made even on the surface. All this would mix the fresh soil that was brought to the surface at the time of trenching with the rest of the surface-soil more properly, and then the whole would be in a much better condition, in all respects, for planting the *young* trees; if, in addition to this, we could afford to give two or three spadefuls of fresh compost from a prepared heap to each plant, as the work proceeded, I should say the whole put together would be as much as any planter could do under the circumstances.

Again. Suppose we decided on the plan of destroying all but the very best plants in the old shrubbery, and finding that the nature of the subsoil did not promise a safe addition to that which is worn out already, what is to be done? Why, in that case, the best plan would be to make single groups of such best plants by leaving a few of the inferior ones round, or near them, for a time, then merely level the rest of the shrubbery ground, and turf the whole of it up to the very boughs of such groups, or single specimens, and to have no dug ground at all on the old site. This last plan would make the most telling improvement in the shortest time, for

shrubby borders are entirely out of fashion, except in limited places near large towns, where one likes to have a little of everything. This does not affect the question whether newly planted trees, or shrubs, are better in dug beds, in groups, or singly, in open spaces on the grass. It is certainly better for old trees or shrubs to be planted in beds or spaces that can be stirred over the surface for the first few years. If you only plant a common Beech, on a corner of the lawn, or pleasure-ground, you expect it to grow faster and to be more vigorous than another Beech-tree planted out in the park or forest, because it is under the eye of the gardener. To meet your wishes, the gardener makes a hole four feet in diameter, and as deep as his ground will allow of, for the Beech, and he mixes two barrow-loads of good soil with the best soil from the pit for planting the tree in; he raises the soil in the centre of this pit six inches above the grass, and plants your Beech, then stakes it, and reduces the size of the pit one-half by laying the turf so far rising in a very gentle slope; he waters it in the summer, and if you notice how fast it grows, he will be sure to water it the more, and to give liquid-manure at times; but if you grumble at him, and say the Beech will never make a big tree, he will take you at your word, and the tree may go to Halifax sooner than he should water it again, unless you are on the spot; and if you are, forced growth does not suit Beech-trees at all. As soon as the roots of this Beech get away below the grass, and out of the influence of hand-watering, he covers the space over with nice turf; and the soil has now settled so much that you can perceive but a slight rise from the rest of the lawn. What is right for a Beech-tree, in a garden, is right for a whole shrubbery. As soon as the plants can take care of themselves, the best and cheapest way is to turf up to them.

On the other hand, if you desire to have a group of evergreen Oaks here, another of scarlet American Oaks yonder, and so on, with groups of one kind or of mixed kinds, there is another rule for them:—the gardener gets as many long poles, sharp at the bottom, as you want plants in the group; he whitewashes the poles as he would the walls of his cottage, and, may be, he will fasten a bunch or branch of the kind of tree to the top of each pole, and he sticks them in the ground just where you want the group, and at such distance from each other as he thinks necessary for the trees to stand apart, and there they will remain for your honour until you can judge of them from the drawing-room windows, or from the front or back-door, or from a bend in the carriage-drive when you return from shooting. When you decide on the very places for the trees, or shrubs, the rule is to break-up and trench and heavily manure the whole space all round and between the white poles; the more irregular the outline, the more knowing your friends and neighbours will take you and your gardener to be; for you must always bear in mind that all these improvements are carried on by *us* and *we*—no matter which of you is master. The right trees are planted, at the right time, where the poles stood, and the rest of the dug, or, rather, trenched ground, is planted with a mixture of evergreens and flowering shrubs,—perhaps Hollyhocks, and other tall, shrubby plants; all these will pay for trenching and for trees, and nurse up the principals to the bargain; but none of them are allowed to hurt the principals by roots or branches, or by shade; out they go, one after the other, as fast as they seem to be in the way of their betters—the principals; the turf proceeds from the outside just as rapidly, and in the same proportion, till at last there is none left to cover, all the temporary plants being removed, and no signs of a clump or shrubbery behind, except that the grass is more green where the ground was loosened; and for that matter, who knows but the very

shades of the beautiful trees caused that striking greenishness—if there is such a word—and so on with all the groups in the garden. Groups of ornamental trees, in a park, and the largest forest plantations, are, or ought to be, planted on the same plan; the principal trees are planted at some given distance apart, so that if you cut down the first, third, fifth, seventh, or any other numbers, the rest will stand at equal distances, and between these come the nurses.

The ground ought to be well and deeply trenched for all groups of ornamental trees, in a park or garden; and for single trees, in a garden, it is better not to go so deep, if the bottom soil is not very good, as when the roots get into bad soil the branches get mossy, and the tree looks bad. When you move a large plant from an old shrubbery, whether the roots are prepared beforehand or not, I would strongly advise some rich compost to be used in planting it in a new place, or else some very rotten dung to be mixed with the natural soil of that place; this is to prevent the tree, or shrub, from standing still for a season or two. Nothing pays so well as a generous treatment at first for all large trees that are moved, or for small ones, when it can be done. For mulching young or old plants after planting, the best thing is short littery dung, half-rotten; and the next best is tan fresh from the tan-pits; and the third best is the same after it is used for bottom-heat in pine or melon beds. All plants of any value ought, certainly, to be mulched the first year, at least; but fresh tan will last three summers if it is an inch thick at first; and birds are not so apt to scratch it about as they do any kind of dung.

All this applies, generally, to such places as our Irish friend has got into, and yet, perhaps, not particularly to his case. He was among our earliest subscribers, and has followed us out through thick and thin, and now it is but right that each and all of us old writers should give him a lift as far as we can understand his newly-acquired property; but either of us, on the spot, could tell him more to the point in one hour than we can by writing till our fingers ache. Next week I must report the meeting of the Horticultural Society; but I shall soon give him such a list of the best new and old plants, and all that I can think about them, as will make a standing reference for the whole of the season to many more besides him and D. BEATON.

A GROUP OF PLANTS OFTEN ASKED ABOUT.

EGG PLANT.—This is the *Solanum melongena ovigerum*, and of this there are varieties with violet, red, and yellow-coloured fruit; but the white is the great favourite with our young friends, as it so closely resembles a common-sized egg, only being more transparent and shining. I recollect, a few years ago, when a large, fine plant of the white variety engrossed more attention in a corner of the greenhouse than any other plant in the garden. Another variety, *Solanum melongena esculentum*, is chiefly distinguished for the prickles on the stem, leaves, and calyx of the flower. None of these would be cultivated either for the bloom or the foliage. The fruit, or, rather, its hard external shell, is the attraction. There is a little difficulty in getting a good healthy specimen in-doors, owing to the plant being very liable to the attacks of green-fly and thrips, for which fumigation and syringings are the only remedy. So liable are these plants to these insects that I have frequently bundled good specimens to the rubbish-heap lest they should infest more valuable things in their vicinity. I have never tasted them cooked but once, and that was enough, though fried with butter,

pepper, salt, &c.—appurtenances with which even flint stones are said to yield a rich sauce—but I do not profess to be a judge in epicurism. When well-ripened, and kept dry, the fruit may be preserved for many months. In March, it will be desirable to sow the seeds in a hotbed, and to prick the plants off as soon as they are three inches in height, placing three round the sides of a four-inch pot. In a few weeks they will want a pot of that size for each plant; and, by-and-by, another shift will be wanted. As the month of May comes more air must be given, so as to lower the temperature, so that the plant, after frequent shiftings, may stand in an eight or ten-inch pot by the middle of June, when it may be transferred to the greenhouse, after being gradually hardened off by more and more air being given to them in the hotbed. If the situation is warm, and a south wall has an empty space, a number may be planted out there, and trained close to the wall; but they will not ripen kindly unless in a warm season and in a sheltered place. The soil used for pots should be light and rich, consisting chiefly of loam and leaf-mould, or very decayed manure. Plenty of water must be given during the growing season, and no lack of the syringe over the foliage, or it will be impossible to keep the plants in a healthy condition. The Egg Plants are natives of Africa.

CAYENNE PEPPER AND CURRY POWDER PLANTS.—These, when unadulterated, are the produce of different species and varieties of *Capsicum*. The word is derived from *kapto*, to bite. I once saw a mischievous little urchin, who would try his fingers and lips upon everything within his reach, so stung with setting his teeth through a cherry-shaped *Capsicum*, that I thought he would never bite more. To add to the mischief, he had worked the fruit between his fingers and thumb, so as to break the skin inadvertently before he pounced it into his mouth, and then, in his agony, he must needs rub his nose and his eyes with these same fingers, until he screamed and danced with torture.

The kinds generally cultivated are almost endless varieties of *annuum*, consisting of various forms and colours of fruit, natives of India and South America—*cerasiforme*, cherry pepper; *baccatum*, the bird pepper; *grossum*, the bell pepper; and *frutescens*, the chilies, or Cayenne pepper; though the latter pepper is made from grinding the seeds and outside coverings of all sorts, especially those that are red. The last-named kind, if kept in a plant-stove, pruned back, and fresh potted, or well top-dressed every year, will yield large crops for a number of years, and from its habit will be neat and compact to look at.

The fruit is used for pickling when green; for mixing with other pickles; for placing in vinegar, so as to form Chili vinegar; and for grinding, as we have seen, when ripe, for pepper; and when in this ripe state the plants have a very gay appearance in the front of a vinery or a greenhouse; as, unless in favourable situations, they do not often ripen sufficiently in the open air, though forwarded under glass until the end of May. Some years ago, some poor attempts at wit were made by associating the name of a nobleman with the recommendation of a little curry-powder, in a glass of warm water, to the labouring man, when wet and weary; but we know, from experience, that a very little of this powder, or Cayenne pepper, or a few drops of Chili vinegar, in such a tumbler of water, if not too often repeated so as to give a false stimulus to the stomach, will not only be grateful, but check many an incipient disease that springs from wet and cold.

In growing these plants for pickling, the seeds (which may be kept in their ripe cases until wanted) should be sown under glass, towards the end of March, and if in a hotbed all the better. As soon as the plants are four inches high they should be pricked off, either singly in

small pots, or four in a five-inch pot, and well watered, syringed, and smoked for the green fly, and shifted again, if necessary, until the first or second week in June, when the plants may be turned out into nice mellow soil, in front of a south wall, in front of forcing-houses, or on a south border, when a good quantity of green fruit will be obtained in September and October.

To obtain beautiful plants with ripe fruit, for the greenhouse, the plants would require to be shifted separately, or three in a six or eight-inch pot in May, and be kept rather close until they were moved to the greenhouse about the end of June. Good drainage should be given, the soil should be light and rich, plenty of water given both to roots and foliage, and green fly started as soon as one presents itself. Nice *Chili* plants may be grown separately in six or eight-inch pots, and, if not potted every year, they should have the old surface-soil removed, and fresh added, of equal portions of loam and rotten dung. In addition to this, they will drink in manure-waterings with avidity. When a number of kinds are grown, few things look more beautiful in a house in the autumn months than nice plants well stored with ripe fruit, of various shapes, sizes, and colours.

THE CAPER PLANT.—Some well-to-do people would think the best beef but poor fare without a supply of Horse-radish and mustard, and to them Caper-sauce has an indissoluble association with boiled leg of mutton. The plant from which the true Caper is obtained is the *Capparis spinosa*, a rambling, trailing-like, spiny shrub, that flourishes in dry soils somewhat calcareous, and in situations fully exposed to the sun, in the south of Europe, the Grecian Archipelago, the Levant, and the northern shores of Africa. It has been tried in many parts of England, but, though it has lived many years, it has seldom produced many flower-buds unless when under glass. In an orchard-house, or fastened to a conservative wall covered with glass, there is no doubt but it would grow and produce its flower-buds in abundance. In such circumstances, or even on dry, warm positions in the south of the island, the practice followed out near Toulon would be the best to adopt, namely, to get the base of the shoots well-ripened in the autumn by a strong sun, and withholding water; and then, towards winter, cut the shoots well down, and cover the stools with moss, or earth, as we do with large *Fuchsia* plants that we intend to furnish us with strong flowering shoots from the bottom next summer.

When grown in a pot in the greenhouse, the pruning should not be anything so severe, but the treatment should be regulated, so as to supply a great number of young shoots not over-strong, and yet strong enough to yield abundance of flower-buds. A twelve or eighteen-inch pot will grow a nice plant; and loam and peat, with a little chalk or lime-rubbish, will suit it. It is easily propagated by pieces of the shoots, and divisions of the roots, and also by seed, when obtainable, but then it should be sown as soon as ripe. The plant can scarcely have too much sun after it begins to grow.

As an ornamental plant, the Caper is rather attractive; the flowers are numerous, large, white, with veins of lilac and red at times, and the centre filled with almost numberless stamens. The fruit is also used for Capers, but the chief supply is obtained from the flower-buds, which are picked when half the size they would be before they expanded. They are then placed, as they can be obtained, in a vessel, and covered with vinegar holding salt in solution. To keep them nice and green, a preparation of copper is often used, or they stand in a copper vessel, or, when arranging the Capers according to their size, they pass through fine copper sieves; but, in this respect, those who eat them just run the same risk as those who indulge in the use of *nice green* pickles generally—that greenness being the consequence

of copper in one shape or other. The public, however, will have their pickles green, and they get them—a doctor's bill, a shortening of existence, are minor considerations. One of the best and easiest-procured substitute for Capers is the green seed of the *Nasturtium*.

CASTER OIL PLANTS.—Our young friends are quite at liberty to trace a connection between these stimulants to eating and the produce of this latter interesting plant. It is the *Nicotia glauca* of botanists, and *Palma Christi* of gardens, owing to its spiny capsules, and its broad, palmate-like foliage. When at home, in Africa, it must have a splendid appearance, as it there takes the form of a tree. In our gardens it is a tender annual. I have sometimes seen it prove its hardiness, the seeds having fallen on the ground, and sprung up the following summer. In general, however, it is best to sow a few seeds in a hotbed in the middle of March; harden them off by degrees, and transfer to rich soil in the open garden in the beginning of June. If the plants have had a shift or two previously they will become all the better specimens. The oil is obtained from pressing and crushing the seeds when ripe, and its strength or virulence will greatly depend on the amount of pressure, that coming from the outer coats of the seed being much milder than that supplied from the interior parts. The oil obtained from the seed of some other spurge-worts is excessively acrid.

R. FISH.

BADORGAN, THE SEAT OF F. O. MEYRICK, Esq.

THIS place is situated in the pleasant Isle of Anglesea, in North Wales, and the gardens are managed by my friend, Mr. Ewing, the inventor of the so-named *Glass Walls*. I had for some time been desirous of seeing these structures, in order to judge for myself, and try to form a correct opinion as to their fitness, utility, or beauty, as garden buildings. The one erected in the Horticultural Gardens, at Chiswick, I have never seen; but I judged, and I think rightly, that if there was any merit or usefulness in them, I should be most likely to see it exemplified in the gardens under the charge of the inventor. I had read, in various gardening publications, some brief accounts of them, and, in some instances, a large amount of a depreciating character of their usefulness.

I had occasion to visit North Wales on business, and resolved to take time by the forelock, and pay these celebrated gardens a visit, even at this dull time of the season. I endeavoured to divest my mind of every idea I might have formed for or against *Glass Walls* previously to reaching the place, and I think that I am now prepared to give a fair report of them and the fruit-trees growing within them.

For the benefit of such of the readers of *THE COTTAGE GARDENER* as may not know what is meant by *Glass Walls*, as exemplified at Badorgan, I will try to describe them. In the first place, there are a certain number of square brick pillars, in two parallel lines, built so as to receive and support, at the level of the soil, two lines of bearers, inclosing a space of ground, as near as I could judge, twenty inches across. Upon these bearers there is set up, quite perpendicular, two rows of glass lights, or frames, with pillars between them. Their height is eleven feet, and the top is glazed also. Every other light is on both sides made to open by means of a long rod with cranks attached to it, and a revolving wheel at the end. I saw them shut and opened with the greatest facility. The top of this double wall of glass is ornamented slightly with carved bordering, and the whole presents a light and elegant appearance. Inside there is a trellis to which the trees are trained. Peaches are planted on the south side of the trellis, and Apricots

on the north, and the trees nearly reach the top, and must, when in foliage, and full of ripe fruit, and the frames set open, be a very ornamental, agreeable sight. The roof, also, is moveable by a similar contrivance.

The question naturally arises, Are they worthy of adoption in gardens generally? I give it as my decided opinion, after a careful and dispassionate study of the subject, that, with some modification, they are. I am quite willing to allow that as a means of defence they are not. I would only use them as an elegant and useful division of a garden. The first, any one that has seen a Glass Wall will at once allow; and the usefulness, I think, may be equally made manifest. As a means of shelter from the cold north wind, a wall of glass will be equally as effectual as a wall of bricks, and certainly ten times handsomer. Then, the use as a fruit wall is more certain still; for every tyro in gardening knows that a fruit-tree under glass is more certain to produce fruit than one exposed to the atmosphere, even with temporary shelters when in blossom. Under the sheltering influence of this double row of upright glass the flowers will be sure to expand freely, and the fruit set equally as freely, because the free current of air, rushing through the trees every mild day when full air is given, will cause the fruit to set. The ripening of the fruit is also certain to go on satisfactorily, and by having light on both sides the colour will be equally full on every side of each fruit; and, lastly, that important point, the ripening of the wood, will, in such a structure, be certain to be accomplished better than against the common brick wall. Thus the three great points, of preservation of the blossom, maturing the fruit, and ripening the wood, is secured by such a Glass Wall as I saw at Badorgan.

I examined the trees very minutely the first week in this year, and can bear testimony to the perfect state of the wood, the plentiful appearance of round, plump, and healthful blossom-buds, and the particularly clean, bright colour of the bark.

At one end, Mr. Ewing had planted a Fig-tree, on which he said there had been a heavy crop the previous summer, and there was, when I looked at it, also a heavy crop of fruit about half-swelled, quite fresh and sound; whilst on a brick wall close to it the fruit on another Fig-tree of the same kind was completely destroyed by the frost.

The only point I cannot prove is, what kind, if any, was the fruit on the Peaches, Nectarines, and Apricots, during the past season. Mr. Ewing—"and he is an honourable man"—declared to me that the crop had been good, and the fruit excellent in quality; and I believed him. Is there a man living who would not?

I have now stated, fairly and conscientiously, all that I consider the good points of the Glass Walls, as I saw them here. They are, undeniably, beautiful structures; they are useful, because the trees enclosed are certain to produce an abundant crop of fine well-ripened fruit; and another point, which I have not alluded to before, is that there are no hiding places for noxious vermin or insects, as in the old nail-holed brick wall.

The improvements, or modifications, I would suggest, consist in making the enclosed space wider, so as to allow space for a spectator, or the gardener, to walk between the two rows of trees. An iron trellis to walk on might rest upon bearers from the pillars that support the structure, and thus the pressure upon the soil would be avoided. I would, also, have means of giving air below the glass lights and above, by opening the roof only, thus avoiding the risk of breakage from sudden gusts of high winds blowing against the open windows and the trees. (I have to notice another Peach-house in these gardens where this point is adopted.) Another improvement would be the introduction of divisions, glass of course, in the wall, one or more of which divi-

sions might be heated with hot-water; and thus a succession of crops obtained.

In another part of the gardens there is a noble Peach-house, which may be termed a glass-covered wall. It is three hundred feet long, six feet wide, and thirteen feet high. The glass front is perpendicular, and the narrow roof is glazed also, and forms a short span-roof, one-half of which is made to open upwards. To bind the front lights to the wall and the front glass, there are, at certain distances, some flat iron bars, through which holes are made to admit a long rod, to which rod there are attached cranks, worked by vertical and horizontal wheels. These are attached again to an upright, strong, iron rod, about four feet from the ground, where there is another horizontal wheel, and a kind of barrel with ribs, which fit into the teeth of the wheel. When air is given, by means of a windlass the ribs of this barrel hold the wheel fast in its place, and thus no ordinary wind can move the opened lights. This is the house I alluded to as having the front lights fixed, air being given under them; but Mr. Ewing says, the top sashes, when open, cool the house quite enough, because the heavy atmospheric air is pressed down through the openings. The whole of this is made of glass and iron, and cost about £400. Standing at one end, and looking through this long avenue, as it were, of Peach-trees, this house has a surprisingly good appearance.

There is, also, a greenhouse in the same garden, formed on every side with upright glass, and a ridge-and-furrow roof. In this house I noticed numerous good specimens of the usual greenhouse plants, such as *Aphelandra*, *Boronia*, *Eriostemon*, *Polygala*, and other New Holland shrubs. In a pit I saw some well-formed *Heaths*, which had been planted out in a bed of leaf-mould in the same pit for three years, and had, in consequence, formed themselves into dense bushes, without the tedious process of tying-out, as practised by the metropolitan exhibitors. They were taken up with balls, and potted during this last summer, and certainly had a healthy, dark green appearance when I saw them.

The Vineries here have been planted about three or four years, and the Vines are remarkably strong and promising. The borders are protected in a most capital manner, being regularly thatched with straw—that is, a frame-work is formed leaning upon the front of the house, and resting upon a foundation close to the walk. This frame-work is then well thatched, and the border, consequently, is rendered much more dry than if the straw had been in actual contact with the soil. When I was there the ends were open, but when forcing commences, I understood these would be closed. I should think the distance from the thatch to the soil of the border next the house is about two feet. I suggested that Mushrooms might be grown under this thatch, and was informed that spawn had been put in for that purpose.

Speaking of Mushrooms reminds me, that in the Mushroom-house I observed what I took for a new vegetable, but soon found out it was nothing else but *Turnip tops*, blanched. I was assured they were very delicate eating, much more so than Sea-kale itself. This is worthy of general imitation.

Badorgan is situated close to a creek of the sea; and in the pleasure-grounds I was much gratified to find that fine tree, the *Araucaria imbricata*, is not at all affected by the sea breezes. I saw about fifty of them, averaging from eighteen to twenty feet high, well formed, dark green, healthy, thriving trees.

In the woods and plantations the *Rhododendrons* thrive well, and there are some very fine specimens of the best hybrid varieties.

Silver Firs are the predominating evergreen forest trees, and, like the *Araucaria*, seem to brave the sea breeze with impunity.

I could fill another sheet with notes on this place, but, as I have already exceeded the usual space allotted to me, I must conclude by saying that I was much gratified, and, I will add, instructed in many points, by my visit. In summer the place must be beautiful; and, if I am spared, I will visit it at that season, and give a further report of the progress of the trees on these Glass Walls. I must, however, just notice that Mr. Ewing has invented a new kind of hot-water pipes, for which, if they answer his expectations, he intends to take out a patent. That fact, of course, prevents me saying another word about them, only this—I think they are very likely to supersede any now in use.

T. APPELBY.

THE MANAGEMENT OF LONG-WOOLLED EWES AND LAMBS.

HAVING, in several former papers, gone into the management of Down and other short-woolled sheep, it is now my intention to treat chiefly of the long-woolled breeds, such as the Cotswolds, Lincolns, Teeswaters, &c., although the same observations will apply equally well to other varieties, that is the Leicesters, Kents, Devons, and the crosses. I propose to consider the best mode of management for Ewes and Lambs of these breeds when kept in pasture districts, or upon farms containing a small portion of arable and pasture land in connection.

I have noticed, in nearly every county, that there are circumstances, in connection with soil and situation, which render a variation in the treatment of stock necessary, yet there are general rules which may be said to apply in almost all cases where the breeds of sheep are nearly allied. In treating this subject, I think my object will be best attained by alluding to it under two separate heads—first, the method to be pursued in rearing fat Lambs; and, secondly, that required for the rearing of stock Lambs for grazing at a future period. The first part of our subject is, certainly, a matter of great importance, and one upon which will, in a great measure, depend the profitable consumption of grass and other green food. I also intend to speak of stock kept upon farms consisting entirely, or in greater part, of pasture land. The first object in raising fat Lambs should be to select that breed or cross which will make the greatest weight of meat in the least time, of that quality most in esteem by the purveyor and consumer. I shall first observe, that although many advocate the pure breeds of Leicesters, Cotswolds, and others, for rearing fat Lambs, yet the far greater number of graziers prefer a cross either of the South Down or Horned Dorset, these being both short-woolled breeds. This cross exercises a beneficial influence upon the wool, and general appearance of the Lamb; and in case of twin Lambs this is especially desirable, because they generally require three weeks or a month extra keeping, during which period the pure long-woolled breeds become hollow in the coat, thereby depreciated in value as fat Lambs in the live market; at the same time, it will be found that the quality of meat to the consumer will be improved in nearly the same proportion as the

general appearance is by the close wool. The cross of short-woolled sheep being advantageous in this case, it is best to decide which breed should have the preference. I think it must be admitted that the Horned Dorset is the best cross of the two, for I find that the produce in Lambs will be greater than it will from the Down cross; and although there is no greater propensity to fatten at an early age in the produce of the former, yet it is equally so, and the greatly increased growth, as compared with the latter, makes the former the more profitable. I can safely say, that I have often seen the most perfect fat Lambs that it is possible to rear from the Long-woolled Ewes when they have been put to the Horned Dorset Rams. Many persons, inexperienced in the result of such a cross, may fancy that the Lambs would come horned like the sire, but it is a fact, that ninety-nine out of every hundred will come polled Lambs. I mention this, because it is well known that horned Lambs are not appreciated in the live markets.

The Tup may be turned with the Ewes during the month of September upon farms consisting partly of arable, such land being generally tilled to produce root-crops for feeding Ewes and Lambs before the pastures are ready; but upon pasture farms the month of October will be soon enough; for it is not desirable, in this case, for the Lambs to come long before the grass is ready for feeding.

The mode of keeping the Ewes during pregnancy must now be considered; and upon farms containing some arable land, where roots are cultivated, they may be made use of for feeding the Ewes, in connection with hay, during the winter months; but, at all times, care should be taken not to resort to root-feeding until all the grass is consumed, and this may be made available for a considerable time, when the aftermath is allowed to accumulate and kept in reserve. The best roots are Cabbages; but failing these, the Swedish Turnips are better than any variety of common Turnips.

Again, upon a purely pasture district, the Ewes, not having the advantage of a root-crop, must be kept entirely upon grass or hay; and by carefully preserving grass in the pastures, such as may have arisen after the month of August upon any dry soil, this grass, when held in reserve for the winter, will furnish the best possible food for in-Lamb Ewes. The lambing-time for this description of stock is not usually attended with so much risk as those breeds which Lamb at an earlier season; and it is quite sufficient, where the farms are sheltered, to keep a shifting-fold on the driest pasture, and if screened from the north by fences it will then not be necessary to resort to the use of a shed and fold yard. It will, however, be quite requisite that great care and attention should be paid to this breed of Ewes at the lambing-time; for although much of the risk consequent upon bad weather will be avoided, yet the ordinary casualties which occur will demand the utmost vigilance of the shepherd by night and by day. The method of treating the Lambs whilst young, including castrating, &c., has been treated in detail in a former paper upon the management of Down Lambs for fattening.

From this period, the Lambs with the Ewes will be able to go into the pastures for grass-feeding, and this part of the season may be considered the most important of any, for it often happens that the season is backward, or the farms cold and exposed. In either case, the Lambs will be ready for the grass before it is sufficiently advanced in growth to afford them sufficient sustenance without the additional aid of roots, or artificial feeding. I, therefore, recommend that upon every farm possessing arable land Mangold should be grown, and held in reserve for the stock at this critical period of the year; for in case the Lambs receive a check from insufficiency of food whilst young, they never recover it so far as to make first-rate fat Lambs. The Mangold, in this case, should be cut and placed in troughs for the Lambs in advance of the Ewes, as also oil-cake or corn until the grass is become abundant; but the Ewes may receive their Mangold strowed over the grass land every day, and the grass should be partitioned off in folds until the fields are covered with a sufficiency to admit of being (what is called) stocked for the summer. Upon those soils which are rich enough to fatten Sheep by the aid of its own produce alone, it is customary to reckon how many Ewes and Lambs may be fattened upon an acre, and turn in the number required, there to remain until the Lambs are fit for the market. On these soils they are often kept in connection with bullocks; the land being stocked, according to its capability, with both beasts and sheep; and from the quiet habit of the long-woolled breeds they are found to do well when pastured with bullocks. On the contrary, the Down breed of Sheep is not found to answer well on stocking pastures upon this plan, either by themselves, or in connection with bullocks; for being of a roving habit, they trace the fields backwards and forwards, rendering the food quite distasteful to the cattle as well as themselves. Hence, the almost universal practice, where Down Sheep are kept, of giving their daily allowance of food by advancing the hurdles on to fresh ground.

I have noticed the promiscuous mode of feeding upon grass land adopted where the produce has been quite insufficient to fatten the animals, and, in consequence, I advise, that wherever the grass produce is not of rich quality, the stock should be continually advanced, by receiving, in addition to their daily portion of grass, a supply of roots, or artificial food, which will not only make good any deficiency in the feeding properties of the grass, but will greatly improve the value of the produce in future seasons. Under the foregoing method of management the Lambs will be fit for the market at from twelve to fourteen weeks old, at which time the Ewes, also, will be forward in condition; many, perhaps, fat enough to sell at the time the Lamb is sent to market; but in this sort of Sheep the wool is valuable from its quantity, particularly when kept upon the strongest soils—it is, therefore, desirable to make it a rule never to sell the Ewes until they have been fleeced, and there is no breed of Sheep which look so well out of their wool as the Long-woolled and their crosses, and realise in proportion a greater price in consequence.

This kind of stock ought always to be sold off fat before Michaelmas, because the grass loses its fattening property after that time; therefore, the most backward Ewes, or those which may have reared twin Lambs, should be forwarded by corn or cake feeding.

R. BLUNDELL.

(To be continued.)

THE MAIN CHANCE.

(Concluded from page 267.)

By the Authoress of "My Flowers."

"FREDERICK JONES' voyage had been very prosperous, but his troubles on landing were overwhelming: the expenses of moving his goods and chattels from shipboard were frightful; and the difficulty of obtaining shelter almost incredible. There was an evident attempt to put the best face upon things; but it was at the same time so clear that he would have given anything to be able at once to return, that the struggle to brave out the undertaking would have been amusing had it not been so painful. He had received one or two offers of employment, but he could not decide whether at once to advance to the diggings, or to engage in his own trade.

"The scenes of reckless intemperance and outrageous wickedness, evidently had shocked his mind, while the loss of his domestic comforts, and the gentle attentions of an excellent and devoted mother, were clearly much felt. He wrote, "Tell my little brother John not to think of coming here until I send for him;" and he quaintly added, "that will be many a long day first." He hoped, he said, in a few years, to save enough money to enable him to return with a realization of an independence. This, he admitted, was the aim of almost the whole of the population; no one seemed to have made up his mind to be a permanent inhabitant; alas! how few of those who are sanguine enough to entertain such a notion will ever realize their anticipations!

"Months again rolled on, and the arrival of every Australian mail was eagerly looked for by the friends of Frederick Jones, in the hope of its bringing further intelligence from the absentee; nor were they disappointed, for early one morning a letter in his well-known handwriting was given to the father, and was read with eagerness aloud to the whole family. Frederick was working about sixteen miles from Melbourne, on the road to the diggings, where he was receiving ample wages, which probably might have enabled him to lay aside a weekly sum towards the fund to enable him to return home, had not the expense of food and raiment been exorbitant, and lodging fearfully high. He had, too, been unwell, and unable for some time to work at all, but was now much improved in health; and he had been obliged to walk sixteen miles to post his letter, and to return the same evening, making, as he said, "a tolerable walk" for such a purpose. These were still more decided symptoms of regret at having left England, and a strong recommendation to all to pause before they decide upon emigrating. The climate, he said, evidently did not suit a large proportion of the emigrants; and fevers and dysentery were frequent.

"About the same time of the same day another letter was received in the town, brought by the mail from South Australia, and directed to the parents of the young man who accompanied Frederick Jones. The date of this letter was about three weeks later than the former, and sad, indeed, was the intelligence it brought! The writer, who had opened a small store, was suddenly summoned to attend the sick-bed of his friend, whom he found prostrated with typhus fever, insensible to all around him, and evidently in great danger. The doctor said the case was not without hope, but everything depended upon careful and judicious nursing. No tender mother was at hand to minister to his wants; and the young friend alone undertook its arduous duties. For three days and nights he never left Frederick's bedside, and had to undergo, alone, all the overwhelming anxieties of watching over him. Sometimes, in the paroxysms of delirium, poor Frederick would throw himself from the

bed, and it required all his companion's corporal strength to restrain him from doing injury to both. Not one coherent word escaped his lips; and the only indication he had of his being at any time sensible, was when he folded his hands, as if in prayer, and a slight movement of the lips strengthened the hope that he was so engaged; and thus his soul passed away to stand before the throne of Christ.

"So ended the career of our poor favorite! Carressed and beloved at home, he died in a foreign land, with no ministerial attendance, nor in possession of the ordinary comforts of the poorest man in his native country. And for what was this sacrifice made? For the vain and delusive hope of heaping up earthly treasures, "that moth and the rust corrupt, and that thieves break through and steal!"

"Poor Jones was buried by his only friend at the least possible cost; but, nevertheless, the doctor's and undertaker's bills, and other incidental expenses, left about £25 to be made up in the best way that might be; a sale of his few effects produced a part of the sum, and his friend made up the deficiency.

"How great the shock was to his parents I need not describe. To hear of his health and death in the same day was a blow that few could bear with calmness; and the Jones's were no exception to the generality. I may just add, that the friend's letter was a very desponding one, weighed down as he was by the death of Jones. He had made up his mind to return with all possible expedition, for he stated, that although more money might be made often than in England, yet everything was so expensive, and sickness so prevalent, that no saving could be effected."

Dear readers! the history of Frederick Jones is a very striking, and a very awful one. He was wishing to be rich. The love of money, and not the command of the Lord, sent him forth, from parents, home, and quiet business. When we go into places where there is no fear of God, no means of grace, and no word from the Lord to point out our way; there, depend upon it, we take no blessing with us, and put ourselves in the way of such temptations and troubles as must end in bodily and spiritual harm. The Romans, in ages long gone by, had what they called an oracle, which they took no step without solemnly consulting. *We* have an oracle; let us consult it in all our doings. *Our* oracle is not one of flesh and blood, hidden in some mysterious place, like that of the poor benighted Romans; but it is the Word of the living God! What says it to those who are seeking their worldly good? "Godliness with contentment is great gain." "And having food and raiment, let us be therewith content. But they that will be rich fall into temptation and a snare, and into many foolish and hurtful lusts that drown men in destruction and perdition. For the love of money is the root of all evil; which, while some coveted after, they have erred from the faith, and pierced themselves through with many sorrows." "Seek ye *first* the kingdom of God and his righteousness, and all these things shall be added unto you." Oh! that we would lay these things to heart! That we would *pray* more for our daily bread, and not go seeking it in the waste places of the earth! I have never yet *heard* of a man who feared God going to the gold-regions; he dares not.

Let us reflect how dreadful it must be to lie on a sick bed in a strange and heathen land; to feel that time, health, blessings, life itself, have all been wasted and misused! that the Great Account is at hand! What a main chance this is to toil and struggle for! Depend upon it, readers, "the kingdom of His righteousness" is the only real and certain main chance. Let us dig in the Lord's gold-fields.

ALLOTMENT FARMING—FEBRUARY.

AFTER one of the most severe winters on record, more keen, indeed, than the notorious hard frost of 1814, which those of our cottage friends who possess a bleached crown will remember, we are at last placed on the threshold of a rising spring; hard weather there still may be, but it is at least a consolation to remember that we have got rid of a dull, dark December, and such a January as will be long remembered.

But there are no new things in this world. Since time began, the history of the human race is altogether a chain

of varied character, link after link produce shades of difference, and yet, when the whole chain is viewed, cycles, or groups of events, or conditions, present themselves to the mind as coming round again at intervals. Indeed, if it were not so, how could the great balance be restored? If we have a repetition of cold summers, how shall their chilling effects be counter-checked but by some possessing an unusual degree of heat? If we have, like the starving and sloppy years of 1816-17, too *neh wet*, do we not generally find that nature, in a compensatory way, sends certain periods of drought, perhaps combined with much heat, and which just serve to restore the balance.

Therefore, our cottage garden friends and those who deal with the allotment system, which one day will receive a far broader development, take heart; although your Cabbageworts, Lettuces, &c., have quailed beneath the stern dominion of the ice king of 1854, yet take courage through the fact, that the sun will shine not a whit the less when spring arrives; and, with April showers combined, will again give rise to the same lightness of heart and heel as came to pass in the days of our forefathers.

Whilst writing this, I must remark that the past severe weather has been one of no small trial to the lowly. Everything on the rise but fires with the poor; an unusually hard period as to weather; Potatoes only in the hands of the affluent or the grasping; even such root-crops as Swedes, Carrots, Parsnips, Beet, &c., partaking of the general tone of trade; the whole, of course, biased in the main by the price of Wheat; then, I say, this, with more, had I space for further observation, will prove, to all feeling minds, that much privation, if not suffering, has been endured. But how plain the endurance of these things proves that John Bull, although a notorious grumbler, is by no means a revolutionist.

It shows the endurance of the masses, and points, in unmistakable language, to that under current of feeling which evinces the secret faith they have in the solidity of our free government. The character of the pending war, too, will set forth the character of our time-honoured institutions in a bolder light than ever; the desperate character of some of our semi-barbarous nations will surely teach our countrymen a lesson they will not speedily forget.

But to our allotment matters. If any of our readers have been what is termed frozen out, they have surely had an excellent chance of attending to drainage affairs, manuring, hedge or boundary dressing, &c., and of clearing and collecting the residue of everything that has once been alive, in order to increase the manure heap. There will be, doubtless, plenty of *soot* this spring, for much firing must of necessity have been used.

I have always strenuously advocated carefulness over this valuable stimulant, and still think that the most profitable and economic way of using it is combined with good Peruvian guano, and the remains of very old wood stacks, old manure become a soil, &c., and which our chemists have dignified by the title of humus. This may be prepared before hand, and kept out of the reach of others for use in drills or on beds. It must be remembered, however, that this is a precious material, and not by any means for "digging-in" as ordinary manure. Its chief use is as a promoter of rapid growth in young seed crops, making them to grow rapidly out of the reach of insect enemies, slugs, &c., and also to steal a march on the summer.

Many crops may be obtained from ground not too much exhausted by the use of this alone; the *Early Horn Carrot* I have grown capitally, by the use of such a material, in beds of about four feet in width, such beds having been a high ridge all the winter, and broken down and well worked in the beginning of February; the compost applied about an inch or more in thickness, and "trickled-in" with a fork to about four inches in depth. The seed then sown and covered with the ordinary soil an inch in thickness. Such beds, for early work, should be thrown six inches above the ordinary ground level, in order to promote a mellowiness in the soil, as stagnation through a low level is one of the greatest enemies of early crops.

The nicest attention must be paid, during this month, to a due preparation of the soil for spring sowings; whether the ground has been ridged and worked in autumn or not, it must by no means be handled when wet. Neither must

the operator think of digging whilst snow is on the ground; this is a most improper procedure, and enough in itself to cause the failure of a crop. It is scarcely too much to affirm that one-half the success of any crop is dependent on the manner in which the soil is prepared in spring. Ground of an adhesive character, and which has not been worked in autumn, should be twice worked, and it will be well to ridge it with deep digging for a month, the operator making up his mind to crop it rather later, which will, indeed, be a matter of necessity.

Most of the spring sowings will, of course, occur in the early part of March, but there are a few things which are better done at the close of February, if the soil is in a friable condition. *Parsnips*, for instance, require a long summer, if they are expected to be fine. Those who grow the *Early Horn Carrot*, too, under high and attentive culture, as we have often recommended in our allotment paper, in order to bunch and sell them in May, when they fetch a high price, must (as before observed) get in the seed about the very end of January, and attend them as early *Radishes*; indeed, the two latter may be sown in alternate drills, at three inches apart, and receive the same attention, which, indeed, they require, and the Radishes being sold off in the end of March, the Carrots will thenceforth have it all their own way; they will then be in drills of six inches distance, and may stand close together in the drills.

It is astonishing how many bunches of Carrots may be drawn off a moderate-sized bed by such good and high culture; that is to say, with a high interest and feeling in the affair. Of course; those who require good, full crops of summer *Peas*, and *Broad Beans*, will take care to sow full crops during this month; a row or two in the first week, and the same repeated in the last week, will produce as many Peas and Beans as the cottage or allotment man has room for in his small plot.

The best Pea is the *Bedman's Imperial*; the best Bean, I think, *Johnson's Wonderful*, or the old *Broad Windsor*, if the soil is strong.

R. ERRINGTON.

APIARIAN'S CALENDAR.—FEBRUARY.

By J. H. Payne, Esq., Author of "The Bee-Keeper's Guide," &c.

THOSE persons who have brought their stocks thus far in health may congratulate themselves, and may also be congratulated, for I am quite aware of the difficulty, the expense, and the trouble; but how mortifying it would be to have an abundant honey season, and no bees to collect it.

FLOOR-BOARDS.—Particular attention must be given at this season in endeavouring to keep the interior of the hives free from damp, which a frequent changing of the floor-boards will tend very much to effect; indeed, after so long a confinement as the late frost has occasioned, it becomes necessary, or the health of the stocks will be much endangered.

FEEDING.—Food must be liberally supplied, but in so doing much attention must be paid to neatness and cleanliness in its administration, for where syrup is used, the greatest care must be given that it be not smeared about the hives and floor-boards, for it will not only cause dampness in the hives, but induce fighting amongst the bees when they are able to fly abroad.

HIVES OF COMB.—Let the hives of comb in which swarms of the last year have died be carefully preserved for the purpose of putting swarms of the coming season into them. The best method of keeping such hives will be, after having cleared them of the dead bees, to hang them up in a dry place, out of the reach of mice or rats. The advantage which a swarm put into a hive of clean, dry comb has over one that is put into an empty hive is very great indeed, and known only to those persons who have experienced it.

HARDY BORDER PLANTS.

(Continued from page 291.)

ACONITUM CAMMARUM.

THE BEAKED WOLFSEASE OR MONKSHOOD.

THIS a fine, tall, spiry-formed, compact-growing plant, is often called *A. rostratum*, even in books. Its roots are tuberous, supported by a large amount of massy fibres, which should not be disturbed at the border-dressing times. Should no increase be needed, these plants may remain undisturbed for many years in the same spots. It flourishes in any good, common garden soil. The whole plant is of a dark green colour. Its stems rise from four to even six feet in height, according to the soil and situation it is growing in. Its leaves are cut somewhat like fingers of the human hand. The whole plant is smooth; the flowers are purple, large, numerous, and panicle; the extreme or main spikes being very long. It is a very showy, desirable, hardy, strong-growing plant; a native of Switzerland, and was introduced to this country in 1752; flowering from the end of June to the end of August. It should be planted in back, or centre rows, either in the beds, borders, or plantations, where it is very useful, for it even does well in situations where it is much shaded by trees, and a little drip from them does not hurt it.

T. W.

POULTRY SHOWS.

SHROPSHIRE.—This was held on the 8th of December, in a building erected specially for the purpose, in the Smithfield, Shrewsbury. For the following report we are indebted to *Eddowes's Shrewsbury Journal* :—

"The Poultry deservedly attracted very considerable attention, particularly among the fair sex, and this department has proved a very pleasing addendum to the exhibitions of stock. In the class of *Spanish fowl*, those of Mr. S. D. Smith and R. D. Newill, Esq., which took the first and second prizes, were considered as very good specimens, but the whole class were scarcely up to par. In the chickens, those of the Rev. S. Donne and Mr. Amphlet, which were awarded prizes, may be considered to have deservedly taken the palm. Of *Coloured Dorking fowl* there were sixteen pens of very fine birds, the prizes being taken by Lord Berwick with the same fowls as were at the Coalbrookdale Show. Four of the pens also drew forth honorary mention from the judges. There were also eighteen pens of chickens of this year, the whole of which were highly meritorious, and some of the pens it were almost impossible to excel. The mere fact of those of Viscount Hill and Mrs. Lloyd, Oswestry, having taken the prizes among such competitors, speaks so highly in their favour that it is unnecessary for us to add another word. Those of the Rev. R. Corbett, of Harnage, were too old to compete in the class of chickens, and consequently disqualified, though really first-class birds. Both classes of Dorkings were pronounced by able judges to be such a collection as has seldom been seen at any exhibition. Passing on to *White Dorkings*, though the class was not very large, the prize birds deservedly won their laurels. We next come to the *Cochin-China*. There were six pens of Cinnamon and Buff fowl, out of which the first prize was taken by Mr. Cattell, with the same birds as have won the prizes at the principal exhibitions in the kingdom. Of chickens there were thirty-one pens of very superior birds entered, more particularly those of the Rev. S. Donne and Lord Berwick, which took the prizes. There were nine entries for Brown and Partridge-feathered *Cochin-China* chickens, among which were some excellent specimens, particularly those which took the prizes. Mrs. Williams, of Eaton Mascott, carried away the first prize for Black *Cochin-China* chickens with the same birds as were so successful at Coalbrookdale. Mrs. Stowe, of Tewkesbury, also exhibited some fine specimens in this class. Mr. W. Lort took all the prizes awarded for *Malays*, but the judges did not consider there was sufficient merit in the class of fowl to award the first prize. In Black-breasted and other *Red Game fowl* Mr. E. Eggington, of Ludlow, and Mr. R. Roden, of Marsh Brook, were the successful competitors against some very fine birds. A whole class of *Poland fowl* was disqualified on

account of the top-knots being trimmed for exhibition, a practice the judges had more than once deprecated. A pen of Silver *Poland fowl* of Mr. E. W. Hazlewood, of Bridgenorth, were splendid birds. The Rev. G. C. Guise took the first, and Mrs. H. Williams the second prize for *Black Lantams* against three other dangerous competitors. The whole class of *Geese* was noticed by the judges as meritorious, and a very fine pen could not compete, owing to their not being entered in time. Those of Mr. Meredith, which carried the palm of the day, were very fine, the gander and two geese weighing 62 lbs. beating any competitors by two or three pounds. Of *White Aylesbury Ducks* there were eleven pens entered, which formed a very attractive group for their excellence; Mrs. Stowe, of Bredon, taking the first, and Mr. T. Jobson the second prize. The first prize for *Rouen ducks* was given to Mr. J. B. Chune, he, however, having no competitor. In the class for ducks of any other variety there were ten entries, the first prize being awarded to a pen of beautiful *Labrador* or *Buenos Ayres*. The *Turkeys*, of which there were four pens entered, were really excellent, those of Miss Meire and Viscount Hill being extraordinary specimens. There were ten pens of turkey poult entered, among which there were some very fine specimens, particularly the prize birds. The class of *Pigeons* was very well represented by all varieties in first condition. Among the extra exhibitions we noticed a remarkable pen, belonging to Mr. S. Jukes, of Shrewsbury, containing an imported hen of the *Cochin-China* breed, with thirteen very fine chickens three months old."

[In the following list *fowl* refers to birds exceeding one-year-old, and *chickens* means those of 1853. Each pen consists of a male and two female birds, and the first prize in each case is £2 2s., and the second £1 1s. unless otherwise specified.]

SPANISH.—*Fowl*.—First prize, Mr. S. D. Smith, Madeley. Second prize, Mr. R. D. Newill, Admaston. *Chickens*.—First prize, Rev. S. Donne, Oswestry. Second prize, Mr. J. Amphlett, Walsall.

DORKING (Coloured).—*Fowl*.—First prize, Right Hon. Lord Berwick. Second prize, Right Hon. Lord Berwick. *Chickens*.—First prize, Right Hon. Viscount Hill. Second prize, Mr. David Lloyd, Oswestry. (The whole class highly meritorious.)

DORKING (White).—*Fowl*.—First prize, Hon. Mrs. Kenyon, Pradoe. Second prize, Mr. H. Foster, Dunstable, Beds. *Chickens*.—First prize, Hon. Mrs. Kenyon. (Second prize withheld.)

COCHIN-CHINA (Cinnamon and Buff).—*Fowl*.—First prize, Mr. J. Cattell, Birmingham. Second prize, Hon. and Rev. H. N. Hill, Berrington. *Chickens*.—First prize, Rev. S. Donne, Oswestry. Second prize, Right Hon. Lord Berwick.

COCHIN-CHINA (Brown and Partridge-feathered).—*Fowl*.—First prize, withheld. Second prize, Mr. H. C. Simpson, College Hill, Shrewsbury. *Chickens*.—First prize, Mr. P. Cartwright, Oswestry. Second prize, Mr. J. Massey, Wem, Salop.

COCHIN-CHINA (Cinnamon and Buff, or Brown).—*Chickens*.—First prize, Mr. James Cattell, Birmingham. Second prize, Mr. T. F. Palmer, Shrewsbury.

COCHIN-CHINA (White).—*Chickens*.—First prize, Mr. W. Lort, Great Heath, Herefordshire. Second prize, the Rev. S. Donne, Oswestry.

COCHIN-CHINA (Black).—*Chickens*.—First prize, Mrs. H. Williams, Eaton Mascott, Salop. Second prize, Mrs. L. C. Stowe, Bredon, Worcestershire.

MALAY.—*Fowl*.—First prize withheld. Second prize, Mr. W. Lort, Great Heath, Herefordshire. *Chickens*.—First prize, Mr. W. Lort, Great Heath, Herefordshire. Second prize, Mr. W. Lort.

GAME FOWL (White and Piles).—*Fowl*.—First prize, Mr. C. Peplov, Wellington. (Second prize withheld.)

GAME FOWL (Black-breasted and other Reds).—*Fowl*.—First prize, Mr. E. Eggington, Ludlow. (Second prize withheld.) *Chickens*.—First prize, Mr. E. Eggington, Ludlow. Second prize, Mr. R. Roden, Marsh Brook.

GAME FOWL (Black and Brassy-winged, except Greys).—*Fowl*.—First prize, Mr. N. N. Dyer, Bredon, Worcestershire. *Chickens*.—First prize, Mr. N. N. Dyer, Bredon, Worcestershire.

GAME FOWL (Duckwings and other Greys and Blue).—*Fowl*.—First prize, Mr. T. Dickin, Ellerdine, Salop. *Chickens*.—First prize, withheld. Second prize, Mr. R. Roden, Marsh Brook.

GOLDEN-FENCILLED HAMBURGH.—*Chickens*.—First prize, Mr. J. Dain, Henley-in-Arden. Second prize, Mr. J. B. Chune, Coalbrookdale.

GOLDEN-SPANGLED HAMBURGH.—*Chickens*.—First prize, Mr. G. Jukes, Beslow, Salop. Second prize, E. Peplow, Wellington.

SILVER-FENCILLED HAMBURGH.—*Fowl*.—First prize, Mr. J. Dain, Henley-in-Arden. Second prize, Mr. E. Gough, Gravel Hill. *Chickens*.—First prize, Mr. J. B. Chune, Coalbrookdale. Second prize, Mr. J. Massey, Wem.

SILVER-SPANGLED HAMBURGH.—*Fowl*.—First prize, Mr. W. Honer, Kingsland. Second prize, Mrs. Corbet, Sundorne. *Chickens*.—First prize, Mrs. S. Acton, Acton Scott. Second prize, Mr. W. Honer, Kingsland.

POLAND FOWL (Black, with White Crests).—*Fowl*.—Class disqualified, the top-knots being trimmed, and the judges strongly deprecating this practice. *Chickens*.—First prize, Mr. J. Amphlett, Walsall. Second prize, Mr. J. Child, Balsall Heath.

POLAND FOWL (Golden).—*Fowl*.—First prize withheld. Second prize, no entry. *Chickens*.—First prize, Mr. S. D. Smith, Madeley.

POLAND FOWL (Silver).—*Fowl*.—First prize, Mr. E. W. Hazlewood, Bridgnorth. Second prize, no entry. *Chickens*.—First and second prizes, no entry.

FOWLS OF ANY OTHER BREED.—(Rumpless.)—First prize, Mr. T. Taylor, Burligh Villa. (Blue Poland.)—First prize, Mr. E. W. Hazlewood, Bridgnorth.

BANTAMS (Gold-laced).—*Fowl*.—First prize, Mr. U. Spary, Markgate-street, Beds. Second prize, J. A. Lloyd, Leaton Knolls, Salop.

BANTAMS (Silver-laced).—*Fowl*.—First prize, Mr. U. Spary, Markgate-street, Beds. Second prize, Mrs. Corbet, Sundorne.

BANTAMS (Black).—*Fowl*.—First prize, Rev. G. C. Guise, Pulverbatch. Second prize, Mrs. H. Williams, Eaton Mascott.

GEESE.—First prize, Mr. Meredith, Frodesly, Salop. Second prize, Miss Ellesmere, Boreton, Salop. (Whole class meritorious.)

DUCKS (White Aylesbury).—First prize, Mrs. Lydia C. Stow, Bredon. Second prize, Thomas Jobson, The Bank, Salop.

DUCKS (Rouen).—First prize, Mr. J. B. Chune, Coalbrookdale.

DUCKS (Any other variety).—First prize, Mr. T. L. Meire, Cound Harbour, Salop. Second prize, Mr. T. L. Meire.

TURKEYS.—Exceeding one-year-old.—First prize, Miss Meire, Berrington, Salop. Second prize, the Hon. Viscount Hill. Birds of 1853.—First prize, the Hon. Viscount Hill. Second prize, Miss Meire, Berrington, Salop.

GUINEA FOWL.—First prize, Mr. T. L. Meire, Cound Harbour, Salop.

TORQUAY.—This Exhibition opened on the 11th, and a more magnificent spectacle in the Poultry line has certainly never been witnessed in the West of England. Nearly three hundred pens were filled with a due proportion of all the leading varieties of Fowls, Turkeys, Ducks, Geese, and Pigeons, in forty classes. The spacious room was tastefully fitted throughout with decorations kindly furnished by Mr. Webb, of the Royal Hotel, and choice plants and evergreens from Morgan's Horticultural establishment, and the arrangements throughout reflect the greatest credit upon the untiring exertions of the Honorary Secretary and Committee. The office of Judge was undertaken by Mr. Edward Hewett, of Birmingham, and when we say, that during the past season he has been selected for the same onerous duty at many of the leading shows in England—at some, as sole adjudicator, at others, associated with the first judges in the kingdom—we need not say anything further with regard to the justice of his decisions. We, however, sometimes find that even justice is not palatable to the prizeless exhibitor, but we are the more pleased to find that the decisions have not merely demanded satisfaction, but obtained it. We have his authority for stating that the classes generally were such as would do credit to any exhibition, especially the *Bull Shuanghae*, Spanish, Dorkings, Game, Hamburgs, Turkeys, and Ducks.

We hope that next year the Committee will correct the manifest injustice and bad policy of giving prizes of less value to the Geese than others. The arrangements for the exhibition-room were certainly the best yet seen at a local show; and the superior quality of some classes were manifest on the most careless inspection. It felt to be seen, that Mr. Channing, of Hewitree, Exeter, again felt disposed to enter the lists against his formidable antagonist, Captain Snell, relying, this time (though so recently defeated at Honiton) on the entry of several fresh pens of birds; the result is identical with the former decision, Captain Snell taking precedence with the same fowls as before; the second prize to the formerly selected ones of Mr. Channing. The American bronze-winged Turkeys still proved how wonderously deceptive, in appearance, to their rivals, they are if brought to scale, as being so exceedingly close-feathered, they weighed seven or eight pounds more than any others.

We are sorry to have to add, that a trustworthy correspondent writes thus:—"I must complain of the thorough want of carefulness displayed in the railway officials in tossing about baskets of *fancy* poultry at the stations; for, travelling as I have lately so much by rail, my feelings have been shocked at their utter heartlessness in this matter; and when remonstrance is attempted, it is no unusual thing to hear, 'they are only a lot of fowls!'"

CLASS I.—SPANISH.—Cock and two Hens.—First prize, Mr. John Marshall, Belmont, Taunton. Second prize, Miss Lydia C. Stowe,

Brendon, near Tewkesbury. Third prize, Mr. Wm. Wevill Rowe, Milton Abbot, Devon.

Class 2.—**DORKING (Coloured).**—First prize, Mr. John F. Pearce, Lower Slepton, Whimble. Second prize, Mrs. Brunel, Watecombe, Torquay. Third prize, Mr. John R. Rodbard, Alnwick Court, Wrington, near Bristol.

Class 3.—**DORKING (White).**—First prize, Mr. Chas. Edwards, Brislington, near Bristol. Second prize, Mr. Robt. Rowse, Torquay. Third prize, Miss Ann Wilcox, Nailsea Court, near Bristol.

Class 4.—**SHANGHAI (Ginamon and Buff).**—First prize, Capt. W. H. Snell, St. Swithin's Lane, London. Second prize, Mr. W. L. Channing, Heavitree, Exeter. Third prize, Mr. Cyrus Clarke, Street, near Glastonbury.

Class 5.—**SHANGHAI (Brown and Partridge).**—First prize, Rev. Grenville F. Hodson, Banwell, Somerset. Second prize, Mr. John Rodbard, Alnwick Court, Wrington, near Bristol. Third prize, Miss Lydia C. Stowe, Brendon, near Tewkesbury.

Class 6.—**SHANGHAI (White).**—First prize, Mr. Cyrus Clarke, Street, near Glastonbury. Second prize, Miss Lydia C. Stowe, Brendon, near Tewkesbury. Third prize, Mr. F. J. Coleridge, Ottery St. Mary.

Class 7.—**MALAY.**—First prize, Mr. Charles Ballance, 5, Mount Terrace, Taunton. Second prize, Mr. Charles Ballance, ditto. Third prize, Mr. Henry Adney, Lymstone, Devon.

Class 8.—**GAME FOWLS.**—First prize, Mr. J. F. Mortimer, Mill-street, Plymouth. Second prize, Chas. Edwards, Brislington, near Bristol. Third prize, J. R. Rodbard, Alnwick Court, Wrington, near Bristol.

Class 9.—**GOLDEN-PENCILLED HAMBURG.**—First prize, Mr. Edward Vivian, Wevill Rowe, Milton Abbot. Second prize, Mr. J. Creed, Kingskerswell, Woodfield, Torquay. Third prize, Mr. J. Creed, Kingskerswell.

Class 10.—**GOLDEN-SPANGLED HAMBURG.**—First prize, Miss Kate Paige, Torquay. Second prize, Mr. Wm. Kennaway Sprague, The Quarry, Paignton. Third prize, Mr. Wm. Kennaway Sprague, ditto.

Class 11.—**SILVER-PENCILLED HAMBURG.**—First prize, Rev. St. Vincent L. Hamrick, Milton Abbot. Second prize, Mr. T. Michelmore, jun., Berry, Totnes. Third prize, Mr. E. Vivian, Woodfield, Torquay. (This class was of unusual merit.)

Class 12.—**SILVER-SPANGLED HAMBURG.**—First prize, Mr. J. B. Toogood, Higher Terrace, Torquay. Second prize, Mr. Frank Paige, Torquay. Third prize, Mr. A. Paul, Adwell Lodge, Torquay.

Class 13.—**POLAND (Black with White Crests).**—First prize, Mr. E. Vivian, Woodfield, Torquay. Second prize, Mr. James P. Hine, Thicketon, near Ilminster. Third prize, Major Servante, Hollacombe, Torquay. (The Judge strongly deprecated the pulling out of the anterior feathers in the crests of this class.)

Class 14.—**POLAND (Golden).**—First prize withheld. Second prize, Mrs. Prideaux, Mount Plym, Totnes. Third prize, Mr. Chas. Edwards, Brislington, near Bristol.

Class 15.—**POLAND (Silver).**—First prize, Mr. Cyrus Clarke, Street, near Glastonbury. Second prize, Mr. Chas. E. Coleridge, Eton, Windsor. Third prize, Mr. Chas. Edwards, Brislington, near Bristol. (This was a very good class.)

Class 16.—**ANY DISTINCT BREED NOT SPECIFIED ABOVE.**—First prize, Mrs. Brunel, St. Mary-Church. (Frizzled or Italian.) Second prize, Major Servante, Hollacombe, Torquay. (Parrigans.)

Class 17.—**BANTAMS (Gold-laced).**—First prize, Mr. C. Cooper, Guildford, Surrey. Second prize, Mr. J. G. Gully, Queen-street, Exeter.

Class 18.—**BANTAMS (Silver-laced).**—First prize, Mr. C. Cooper, Guildford, Surrey. (The cock died, but being good the Committee allowed the prize.)

Class 19.—**BANTAMS (White).**—First prize, Mr. Wm. Connett, Upholsterer, 270, High-street, Exeter and Torquay. Second prize, Miss A. M. Northcote, Ashprington, near Totnes.

Class 20.—**BANTAMS (Black).**—First prize, Mr. Wm. Connett, 270, High-street, Exeter.

Class 21.—**BANTAMS (Any other variety).**—First prize, Mr. C. Edwards, Brislington, near Bristol. (Frizzled.) Second prize, Rev. Grenville F. Hodson, Banwell, Somerset. (Silky Japan.)

Class 22.—**TURKEYS.**—First prize, Mr. C. Edwards, Brislington, near Bristol. Second prize, Mr. Elias Blackaller, Maidencombe.

Class 23.—**GESE.**—First prize, Mr. W. W. Rowe, Milton Abbot. Second prize, Mr. J. Blackaller, Maidencombe, Torquay.

Class 24.—**DUCKS (White Aylesbury).**—First prize, Mr. W. W. Rowe, Milton Abbot. Second prize, Miss Ann Wilcox, Nailsea Court, Bristol.

Class 25.—**DUCKS (Rouen).**—First prize, Mr. Thomas J. Brembridge, Heavitree, near Exeter. Second prize, Mr. W. W. Rowe, Milton Abbot.

Class 26.—**DUCKS (Any other variety).**—First prize, Mr. C. Edwards, Brislington, near Bristol. (Buenos Ayres.)

REMARKABLE YEW TREES.

It can hardly fail to have attracted the attention of the most careless of all observers how some soils, seemingly fertile, and producing certain crops in great abundance, refuse to do the same with crops of another kind; for we find, that while one district may be famous for certain

productions, it refuses to support others, save only in a medium way. We have all seen parks and pleasure grounds which could boast their Oaks, and it might be Thorns, and some other trees, of a size and age almost coeval with the Conquest, while Elms, Beeches, and some other trees, were in no respect remarkable for their size or general health, although, in another place, these trees might surpass the Oak, &c. in their vigorous growth, and the effect they produce on the landscape.

As the most illiterate have a sort of veneration for large, old, or remarkable trees, it is no wonder that most of the extraordinary ones, should, by some means or other, find their way into some of the various horticultural works the last few years have given rise to; but as almost every place of note has its large tree, its "king of the forest," or other dignitary, it is not unlikely but the great number of remarkable ones restrains those who would otherwise gladly report them from doing so, thinking they might only be describing what so many had the means to exceed. Be this as it may, there is no doubt but a large number of very remarkable trees have welcomed the summer's sun and braved the winter's blast, for many generations, unnoticed and unknown, except by the rural population in their respective neighbourhoods, to which, memorable event of things long since past, to which, our Editor has invited communications respecting these remarkable objects of antiquity, as well as of those remarkable for their gigantic size, our country friends could not do more service to the horticultural world than by forwarding a faithful description of those wonderful productions which come daily under their eye; and, by way of encouragement to such, I shall, this week, notice two or three in the immediate neighbourhood I write from; beginning, however, with a species scarcely less national than the Oak, and in its massive proportions approaching nearer thereto than many would be inclined to believe, and from the position it is often found in, a degree of sacredness is seemingly thrown over it which goes far to protect its less fortunate brethren when planted in a less honoured situation. I need hardly add that the "Yew" here is alluded to.

At what period this sombre and unchanging tree was first planted in our grave-yards is a point I willingly leave to be settled by the ecclesiastical authorities who have made it their business to inquire; but there cannot be any difference in opinion regarding the taste which selected it out from amongst the many trees indigenous at the time, and I should be very sorry to see or hear of any attempt being made to supplant it by any of those newer productions we hear lauded up so much; but of this there seems little fear. The feeling of veneration for the "Church yard Yew" amounts to something like that in which the village rustic regards the "robin," and the unwillingness to hurt either is manifested in so many ways that protective enactments are unequalled for in either case. This proper regard for the mournful "Yew" is much enhanced when the specimen is such as to demand more than ordinary notice, and it is one of that class to which I wish to call attention.

In the beautiful and romantic village of Loose, which stands in a valley, or gully, through which a small stream of water passes on its course to join the Medway, the parish church rears its head, without exciting any extraordinary claims for distinction beyond others of its class; but near to the entrance, at its western end, a venerable Yew has stood the blast of many a winter. This remarkable tree, when viewed a few yards off, presents nothing extraordinary in its outline, beyond that its foliage seems in excellent health, and extends laterally a greater breadth than the majority of such trees, but not so much as to call for particular attention, while in form it is like most of its class, hemispherical, or nearly so; but a closer approach excites the admiration, if not astonishment, of the inspector—its venerable trunk, rising out of the ground, seems to have presented a straight bole to the height of some eight or ten feet, and then diverged off into branches in the usual way. This bole, which at one time, doubtless, showed its capabilities of furnishing good sound planks for a hall dining table, is no longer what it was then, although, in the eyes of an antiquary, it presents features more beautiful; in one respect, however, it is probably unaltered—it is still

perpendicular, thus showing its stability, and giving promise to afford shade and shelter for many generations of the human race yet to come. Now, I presume that readers will think this is nothing more than many trees similarly placed give promise to, but when I tell them that the trunk of this tree, without presenting any of those uneven humps, or projections, which give a false measurement to their circumference, is, at the smallest part, between the root-claws and the breakings of the branches, no less than thirty-two feet ten inches, they will assuredly give it the credit of being an extraordinary one. True, it is no longer sound; in fact it is a mere shell with several openings, but none exceeding two feet wide, while the shell itself is from six or eight inches to a foot thick. There is space inside for a number of people, and, doubtless, many of the village rustics have, in their younger days, been within its ample enclosure. Of late years, however, the parish authorities have put a fence around it to protect it from the molestation of those who seem disposed to think that the pleasure of viewing an object is not complete without the possession of a portion of it; in this respect, the uninformed rustic is a less dangerous visitor than the learned collector of curiosities. In the present instance, the "iron of oak" has been adopted; the heavy wooden paling conceals as well as protects the object inside, whereas, an iron one need not have done so; however, the inquiring visitor will be able to see sufficient of it to form an idea of its magnitude.

It is also proper to say, that the site of this venerable object is in a narrow valley, or rather on the side of the hill forming it, and the soil seems very congenial to forest trees of most kinds, as well as most fruit trees likewise. Limestone, called here "Kentish Rag," exists in great quantities, and is dug within a very short distance for building and other purposes; and, doubtless, the roots of this tree are in contact with this material. It is needless to say that many other forest trees also present a healthy appearance, but the custom of the neighbourhood with that of former periods having been more directed to the cultivation of coppice than timber plantations, there are no remarkable timber trees immediately near, that I could hear of; besides, the tempting prices given for home-grown timber, some fifty years ago, was too great to be resisted by needy proprietors at that time, hence the absence of extraordinary trees. Nevertheless, at a short distance from the Yew above-mentioned, and in a situation exactly similar, an extraordinary fine Cedar of Lebanon erected its sturdy head. Not having an opportunity to examine it closely at the time, I could only give it a hasty glance, and comparing it with others in my mind, I thought it the finest tree of the kind I had ever seen, being evidently sound, and in the best of health, and of proportions from which a ship carpenter might obtain some six-inch planks, which, as every one is aware of, but few Oaks can furnish.

Continuing the subject of Yews, I may add, that in another Church-yard, some six miles or more from the last, there is another tree of the same kind, which, I was informed, was as large as the last, and perfectly sound. This latter qualification seemed so extraordinary, that I determined on paying this famed tree a visit; and though it fell short of what was reported of it, yet I was not disappointed, for I hardly expected to find a tree, 10 feet in diameter, perfectly sound; this one, however, differed much from the last; with a less expanded top, it presented equal tokens of good health, and its bole, which was not very short, was gnarled and covered with those short spray twigs, or branches, which in a great measure hid it from view; however, a string run round underneath them, and at the distance of four feet from the ground, presented a circumference of upwards of twenty-seven feet; and though I could not pronounce it as sound timber, I am satisfied there were no hollow spaces of any extent. This description will probably make it appear as a more extraordinary tree than the first-named, but then it is to be considered, that at the place where the circumference was taken the girth was more than at one foot from the ground; in fact, the tree presented a sort of barrel-like swell at that height, both above and below being smaller; nevertheless, its size, general health, and comparative soundness, was such as to command

respect. I may also add, that it, too, seems to luxuriate on the Limestone range, although its site was more elevated and exposed, being, in fact, on one of those eminences which command a view of eastern parts of the "Weald of Kent;" and our young friends will find its hill on the county map under the name Uleomb.

A third tree, scarcely less interesting than either of the last, exists in the churchyard at Leeds, near Maidstone, another rural parish but a few miles from either of the last-named. This tree is, however, hollow, and has also the singular form of being much thicker at a yard from the ground than at one foot from it; at the former height it is upwards of thirty feet in circumference, and several openings admit of its holding several persons, who are not in this case debarred by an unsightly fence; but the tree is certainly not so remarkable as the one at Loose, the latter presenting limbs of some five or six feet diameter at the breaking; whereas, those at Leeds are much less; still, it is a remarkable tree, and bids fair to live for many generations yet. It is, however, much exposed; and the barbarous practice of digging graves so near a relic of former times, may, doubtless, tend to lessen the days of this, as well as of many other trees similarly placed; but as this is covered ground, and calculated to excite indignum in the parish authorities the propriety of restricting innovations of this kind as much as possible; and though the anxious wish of some eminent parishioner to be buried under the Yew-tree may seem a duty on the part of those to whom the bequest was made, we are far from certain, that the next generation will regard the injury done to so venerable a relic in the same light. However, as I professed only to describe the trees as they are, without prescribing rules for their future welfare, I must leave the latter part of the duty to more experienced hands; and, in conclusion, will be glad to learn what part of the kingdom can furnish finer Yew-trees than those to which I refer; and hope to find some other correspondent informing us where remarkable trees, either of this, or other kinds, may be found; for I believe that many such do exist, unknown save in the immediate neighbourhood of their site.—A CORRESPONDENT.

THE POULTRY PENTALOGUE.

ONE of the most useful little poultry manuals, with its information, moreover, conveyed in an amusing form, that have lately appeared on this now popular subject, is thus entitled.

The Five great rules, whence its appellation, are thus specified:—1, Pure Breed; 2, Fresh Blood; 3, Varied Diet; 4, Equable Temperature; 5, Strict Cleanliness. Poultry-keepers, indeed, might be at variance as to the manner in which these various requisites would be best provided for, but that these form the main requisites towards success, all would assent to; and wherever failures have come before us, to the neglect of one or other of these essentials has the cause been manifestly referable.

The advice for the interior economy of the Fowl-house is a fair specimen of the form in which the author's recommendations are conveyed, and is so well, and yet so simply, put, that we will now transcribe it for our readers' benefit.

"Brick or stone is too cold for the flooring, which had far better be of lime, ash, or well-beaten earth. The former is best, as it can be more easily swept and kept clean. It should be above the level of the external soil to avoid damp. The whole of the interior had better be plastered, as the rough walls and thatch are likely to collect dirt and vermin. If the roof is tiled and slated, plaster is still more necessary to check the extremes of heat and cold. Two or three coats of whitewash in the course of the summer, especially, will be found very conducive to health."

When we come to directions for feeding and general management equally safe guidance is briefly given.

At page 15 we light on "*the mysteries of Chickendom.*"

* "The Poultry Pentalogue; or Five Rules for Fancy Fowls and Fowl Enclosures." By James Furneaux, Esq., President of the Devon and Cornwall Poultry Association.—W. S. Orr and Co., London; published by R. Lidstone, Plymouth.

where a restriction is placed in the number of consorts to be allowed the male bird. The limit to which our author would restrict the harem, namely, three hens, is, we apprehend, unnecessarily close, and, under ordinary circumstances, we should feel no cause for anticipating inferior produce, provided the male bird be in good condition, where five or six hens were permitted to run with him. Our remark is general on this point, for certain cases would, doubtless, claim exemption from our more liberal allowance, where, for instance, every effort was put in requisition to breed the choicest specimens for exhibition; or where, again, the cock was young, or the narrow boundaries of a small yard was all the space allowed for their run. In former days, also, another class of birds would have been as carefully set apart, namely, the Game-fowls that were destined to produce champions for the pit, where these, and frequently but two hens, were thought as many as would be wisely left with the cock.

Chapter ix., bearing the ominous title "Revolutionary," touches on the question of how far it may be practicable to establish permanent races from cross-breeding the present different varieties. In a matter like this, where the opinions of experienced persons are at variance, we must express our acknowledgment of our ~~mistrust of any such result, as he~~ ^{own thoughts with caution,} but we cannot refrain from an we may judge from trials. At page 11, ~~his theory, while alluding to the delicacy of the Dorking race, which he thinks might be invigorated without any lasting prejudicial effects in the breed, "by the infusion of a dash of Game blood."~~ "The progeny of a Game cock and Dorking Hen will be half-and-half, all of which, with the exception of a single cockerel, should be consigned to the cook, and the survivor should have as little of a Game appearance as possible. If put with Dorking hens, the chickens will be quarter Game; and the same plan being pursued for another generation, the cross will be reduced to an eighth, after which there will be little chance of the birds 'crying back!'"

Now, this argument is based on the hypothesis that in breeding from fowls of different families the produce will present a proportionate combination of the characteristics of both parents. But is this so? In few cases, we believe, is the amalgamation by any means so perfect, and in the chickens of such a brood we should expect to find some bearing a close resemblance to one parent, and some reproducing the features of the other, while comparatively few could be correctly termed half-and-half. If this uncertainty prevailed in the first cross, still more questionable would be the chance of fixing the Game character at the exact quarter in the next generation. Since, therefore, with all our care, we can never be positively certain in what proportions the desired combination may be brought about, the advantages to be gained by cross-breeding fowls appear to present so great a hazard of injuring our pure breeds, that few beyond those to whom the test of the experiment is sufficient to interest will be likely to take shares in this lottery. The introduction of a "pile" Game-fowl into a strain of black-breasted reds is said to have made its appearance after a lapse of fifteen years, when, moreover, for many generations not a symptom of it had been apparent. We certainly believe that in nine cases out of ten the Game blood, in such an instance as that suggested by Mr. Furneaux, would be bred out in three or four generations, from the universal tendency in Nature to revert quickly, in such unions, to the type of one or other of the original parents. All we contend for in this, as in other crosses between the different breeds of fowls, amounts to this, that it cannot be said that such produce generally will exhibit in form, feather, or properties, any very near approach to the proportion of the parents' features to which their origin would entitle them.

But we should be guilty of great injustice to Mr. Furneaux were we to leave our readers under the impression that he himself is in favour of the practice we have just spoken of. So far from it, indeed, that he expressly says (page 22), "But, although I maintain the practicability of forming new varieties, either by taking advantages of the freaks of Nature, or by pursuing some systematic course, I am by no means an advocate for the trial of the experiment. To say nothing of the confusion and mongrelising that would inevitably ensue if the practice were generally adopted,

I do not think that the public taste would encourage the endeavour to inundate us with a multitude of new races. There is something in John Bull's composition, which, so long as he is a *bona-fide* Englishman, acts as an useful drag upon his spirit of enterprise, and reduces its speed within controllable limits. With his descendants it is otherwise; and the go-ahead mania of the United States is continually developing itself in such characteristic proceedings as the manufacture of wooden nutmegs, Aztec children, or Brahma-Pootra fowls, the last two of which have been rejected by our ethnologists and ornithologists during this year. Whilst, I venture to uphold the revolutionary doctrine of the possibility of forming new varieties of poultry, I in no way maintain the desirability of it."

We have said enough to satisfy our readers that Mr. Furneaux's pamphlet is the work of a thoughtful, unprejudiced mind: that, discarding compilation from the labours of predecessors in the same tract, details the actual results of practical poultry-keeping; as such, therefore, it will, doubtless, be duly welcomed by those to whom its subject-matter is an object of interest.

GAPES.—INFLAMMATION OF THE WINDPIPE.

FANCY a young practitioner called to the bedside of a patient who lies gasping for breath in the agonies of suffocation; and fancy the young practitioner, either from want of observation of the symptoms, or from being prejudiced, taking the disease to be inflammation, and treating it as such; and the weakened patient dying, and the cause of the stoppage of the windpipe being discovered to have been mechanical, and with no relation to inflammation at all: What would be thought of that practitioner? If he were timid, hesitating, or erring through want of more perfect information upon the subject, we should pity while we blamed him: now let us carry the simile into the poultry yard, and let the practitioner be the fancier of fowls, who in the course of the year has dozens, if not hundreds of feathered patients, who, if they cannot speak, yet can open their mouths in a manner quite expressive of the character of difficult respiration. How is he to treat these poor little chickens that every *now and then* open their mouths and "gape?" If he belong to the positive school, he will "Pooh! Pooh!" any idea but that of the disease being inflammation, and he will treat the poor *weak little chickens* with Tarrar Emetic, and *they will die*—and it only remains to write a book to prove that they ought to have lived! But if he be a practitioner of the other class, he will, with all modesty, trace effects to causes; he will cautiously observe symptoms without preconceived notions about the nature of the disorder, seeking earnestly what light the experience of other practitioners may throw upon the subject; and the following is a synopsis of what he will find, and which, I think, shews pretty clearly that a great deal that is practical and good has been put forth and verified, step by step, and very much of it in the pages of the "COTTAGE GARDENER."

Fowls seem to be threatened with suffocation from two disorders very different in their nature and symptoms; the first, which is known by the name of "gapes," being peculiar to *chickens*, and being the result of a mechanical obstruction: the other being an inflammation of the windpipe occurring in *full-grown fowls*, and being of the nature of "croup."

Gapes.—In wet, cold weather, or soon after it, the chickens are observed to gape suddenly, and to do so "at intervals," "with a muscular motion of the neck, as if they were endeavouring to dislodge something from the throat," in the intervals of gaping the breathing being natural: experience has shewn that this proceeds from the presence in the windpipe of one or more small red worms, of about three-quarters-of-an-inch in length; and that if these parasites are allowed to grow or develop, that the chicken will die suffocated; an after-examination of the windpipe displaying no trace of inflammation; but, that if the chicken affected with gapes be made to swallow the vapour of turpentine at intervals, or if a small portion of turpentine be passed down the windpipe so as to reach the worms, they will be dislodged, coughed

up, and the chicken, in a very large proportion of cases, will live and do well.

Croup, or inflammation of the windpipe, generally attacks full-grown fowls, and is distinguished from *gapes* in that the *beak is constantly kept open*, while the breathing is harsh and stridulous; thus being evidently an inflammatory affection is treated successfully with Tartar Emetic and warmth, and would be manifestly injured by the application of turpentine, so useful in curing "gapes."

It will be seen, at once, that many of the foregoing symptoms are extracted from the excellent and practical letter of Mr. Tegetmeier, in a late number, and who is so good an authority that I believe I may assume them as facts; I have endeavoured to shew how much they prove, and, that they are of enormous importance, I am sure will be felt by all owners of the valuable breeds of poultry.

I should think the general remarks of Mr. Tegetmeier, together with the undisputed matter in evidence, has put the matter of "gapes," quietly to rest: we are tolerably good practitioners in the disease, considering we had not much guidance from the lamp of science; indeed, the only point which remains is of quite minor importance, though it is of some interest. How do these parasitic creatures get in? I understand parasites hatched from ova, but in the case of the chickens there would be no time for this; and it is difficult to imagine the ova as present in the chicken before it makes its exit from the egg.—JOHN ANTHONY, *Washwood, near Birmingham.*

TO CORRESPONDENTS.

* * * We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of The Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

GREENHOUSE AND MELON-PIT (Rev. J. S. L.).—You wish to heat both by one fire. The greenhouse is 13 feet by 11 feet 7½ inches, the melon-pit is 6 feet from it in front, and 13 feet by 6 inside measure; an open tank has been made of brick and cement, and top-heat, as well as bottom-heat, is required. The first thing, then, to do, is to fix the site of the stock-hole, which should be between the house and pit, or at the end of the latter. In either case, it must be sunk enough to allow the top of the boiler to be lower, six inches or so, than the bottom of your tank. Then, if your stock-hole was between the two, you might have a T piece for a flow and return, taking one into the greenhouse, and the other into the melon-pit, and both in nearly the same level; but, in the latter, it should terminate in a small cistern, to which the flow-pipe for top-heat, and the one for bottom-heat, should be attached, and supplied with plugs or valves to take the heat off, or let it on, at pleasure. If your stock-hole was at the end of the melon-pit, it would be preferable to have the flow-pipe taken into an open cistern there, higher by a foot or two than your pipes for top-heat, and have three holes in that cistern for pipes being fastened to,—one for the greenhouse, one for top-heat in melon-pit, and one for bottom-heat ditto, so that you could stop and regulate the heat in either at discretion. Under such a supposition, you would require two four-inch pipes—a flow and return—round the front and part of the ends of your greenhouse, two three-inch pipes for top, and two for bottom, in your tank, for melons. In each of these cases, see that the flow-pipe rises a few inches to the farthest extremity from the boiler or cistern, and there fix a small open pipe, to be taken outside the building to allow the escape of air. If the bottom of your tank was no lower than you could put your pipes in the greenhouse, and you could depend on your tank holding water, then you might dispense with pipes altogether in your melon-pit, by running a division up the middle of your tank, except at the farther end, taking one end of your T piece into the tank, and the other into the greenhouse, and covering your tank with strong slate, and leaving part of that uncovered, so as to supply you with top-heat. We have seen such contrivances act admirably, but they are not to be depended on like separate pipes. Near the end of our second volume, you will find a most economical arrangement by means of a wooden tank, described and illustrated by Mr. Fish. You will perceive, that under this mode, were the pipes in the greenhouse higher than your tank they would empty themselves into it. Taking the water from the boiler at once to a cistern higher than the highest pipes, and then by means of plugs or valves letting it on where you wish, is the most manageable mode, and, perhaps, the cheapest in the end. You would see, by some articles of Mr. Fish, lately, that when pipes are used for bottom-heat, with plenty of rubble, tanks may be dispensed with; but the latter, even with pipes, are useful for affording a moist bottom-heat. Any of the tradesmen who advertise in our columns would do your work well.

VARIOUS (C. I. S. A.).—Your *Coban* has very likely robbed your *Mandevilla*; they should have been planted in brick divisions. Do not mind the sickly look of the latter now; ours has long ago lost its foliage; prune it rather close by-and-by. Your temperature, 40° at night, and a rise of 10° during the day, is all right. We are pleased the plants you

name are so healthy.—a sure sign you know what you are doing. Do not fret about the *Hydrothamnus fuscicollis*, it is not worth room in the house; it will repay your attention far better against a wall out-of-doors. *H. elegans*, if planted out against a pillar, is one of the prettiest things we know. We have a large plant just now one mass of bloom, and it has never been destitute of flowers for several years.

FEEDING BEES (Honey Bee).—Tin vessels for feeding bees are not at all injurious to them. If your bees are weak, that is, if they have less than seven pounds of honey in store, begin feeding immediately. Payne's lives, &c., are to be obtained only through himself—his direction is "Bury St. Edmund's." If your bees have nine or ten pounds of food in store, give barley sugar; if less, for a week or two, give honey and sugar, and then barley-sugar.

METROPOLITAN SHOW.—F. Bernal, Esq., says—"I am writing to you on Monday evening. I received my fowls back from Birmingham Show on Sunday morning. At six, p.m. to-day, the two pens of Ptarmigans exhibited by me at Baker-street have not made their appearance." This, I think you will agree with me, must arise from great carelessness somewhere. Next week I will let you know where it has arisen, as at present I am not able positively to fix the blame on any one. I will also then, if you will give me space, tell you how to produce the so-called Andalusian Fowls, and bring forward facts."

DISEASED EAR OF RABBITS.—To the inquiry, at p. 292, we have received these replies—"The disease which affects your correspondent's (Aseul's) Rabbits, is, I should suppose, by the description, what is termed, *wax in the ear*. I do not know the real cause of the disease, but the best remedy I ever tried, or heard of, is to remove the wax, or scurf, from the inside of the ear, and apply two or three drops of sweet oil. I have no hesitation in saying this sweet oil may be either Olive or Castor. It may be as well to add, that the symptoms of this disease approaching are continual shaking of the head; and if taken in time may easily be cured.—ORIX."

"I have frequently found Rabbits subject to the ear disease, but the cause I am quite ignorant of. I beg to inform Aseul, if he will occasionally examine the ears of his rabbits, and, on seeing the least symptom of the disease recurring, drop a little sweet oil and turpentine into them, all will be right. I once kept rabbits; and, at my first onset, was nearly discouraged by this rather noxious disorder, but an old fancier let me into the secret, and ever afterwards all went on well. I had no recipe as to proportion of oil and turpentine, but, at the commencement, I procured a half-pint bottle, into which I put a rather large teaspoonful of turpentine, and then filled with sweet oil; this I kept always at hand. I object to picking, or in any way meddling with their ears more than is necessary to drop in the oil, taking care to always well shake the bottle before doing so. I believe the disease is infectious.—D. E."

TRELLIS WITH EVERGREENS (Odemerelaw).—You want just the very same things which all great lovers of, and enthusiasts in, gardening want when they first begin—very choice, very good, very pretty evergreen plants and climbers, or "pretty flowering evergreens," but nature has never thought fit to indulge mortals in such extravagances; and there are no such plants as you ask for, at least, not in temperate latitudes. Evergreen Roses would soon cover your trellis, and soon after that they would be too much confined. We would plant a dozen kinds of the best hybrid perpetual Roses for a division fence, six feet high; and the index to the last volume will show when to look for them, and the best of the evergreen Roses as well.

ÆCHMEA FULGENS (Dan).—Either your plant of this must have been very young when you had it, or you put it in a large pot too soon, and so prevented its flowering, for no plant flowers more freely when well used. Do not shift it this spring, but give it strong peat and moisture from March till the end of June, then less water and a drier place, and you will soon see it in beautiful bloom.

ORCHIDS (Ibid).—Ill-treated orchids are a long time coming round, but you have acted fairly by them since they came into your possession. Continue as you have begun, and trust to patience.

ALLAMANDA (Ibid).—All the Allamandas flower on the young wood made the same season, like the grape vine; therefore, to keep them within bounds, and to get them to flower abundantly, they must be cut in very close at pruning time; but, like vines, if you want them to cover a large space in a short time, you would not cut them in so close in pots. All the wood of last year may be cut down to one, two, or three buds from the old wood.

CAPE BULB (So, Durham).—The leaves sent are those of some *Babiana*, and, we think, of *Babiana plicata*, with purplish little flowers in May. Your plant seems to have been potted early in September, or it has been kept too warm, for it is as forward now as it generally is in the middle of March. These *Babianas* are among the smallest bulbs of the *Isia* tribe; sandy peat is the best for them in pots, and all the heat they require is to keep the frost from them. Your plant will go to rest early in May, but it is doubtful if it will flower this season from May to the end of September. Keep it dry, and, after potting, keep it cool all through the winter; from six to ten of its little bulbs will grow very well in our 48-sized pot.

SPANISH FOWLS.—Mr. Painter informs us, that his birds at the Metropolitan Show took the third prize for Spanish Chickens, his birds having, by mistake, been put into pen 48, which, as in the catalogue, had been assigned to Mr. Taylor.

FOOD FOR DUCKS (Orix).—The following are our directions given in "The Poultry Book":—"We allow them, morning and evening, a liberal mess of steamed Roots, Carrots, Turnips, or Mangel Wurtzel, as the case may be, mixed up with bran and a little barley-meal. The refuse of the kitchen-garden is eagerly devoured, and, where grass is not obtainable by them, must be regularly supplied to them. When feeding them for table, a portion of skim-milk with their meal forwards them very

rapidly." As to the mode of rearing Ducklings, we must refer you to the same work, of which it occupies four pages.

BREAD.—S. E. I. says—"I shall be much obliged by any receipt available for the poor, during the present high price of food, for making Bread with a mixture of Indian Meal, Rice, Barley Meal, or any other article of food cheaper than Wheat." We shall be glad of any communication on so important a subject. Our own experience enables us to recommend the addition of two pounds of boiled potatoes, rubbed through a colander, to half-a-peck of flour.

DAMP AND WATERY SITUATION (H. H.).—The only poultry fitted for such a situation are Ducks.

SHANGHAE (Amicus Galli).—The ear-lobes, and all about them, ought to be red; but we should not consider a white stain upon it a defect preventing the bird taking a prize if otherwise sufficiently meritorious. Is it a permanent stain, or is it merely "white comb," and removable by being rubbed with an ointment of turmeric and cocoa-nut oil? *Hempseed* bruised, and in very small quantities, is useful for young chickens; but we deprecate such stimulating, rich food for the breeding stock. We prefer the second sitting of *pullets'* eggs to the first sitting.

GROWING FOOD FOR PIGS AND FOWLS (Isle of Wight).—Divide your ground into two equal parts, and grow alternately on one-half Barley, and on the other half Carrots, Parsnips, and Mangold Wurtzel. When these crops are off, stee a crop of Coleworts from the vacant ground. This incessant cropping will require very liberal manuring. Of *Pigeons*, we should keep *Runts* for table purposes.

MANURE FOR CELERY (M. P.).—The dung of hens and sheep are excellent for Celery. You may mix them with the soil before planting, and you may make liquid-manure from them for watering the plants while growing.

RADISHES IN FRAMES (J. B.).—These cannot be grown too near the glass; two or three inches from it is not too near. You may sow them now, and have them off before you require the frames for Cucumbers in April.

CARROT GROWING (W. F. B.).—A light, deep soil, trenched, and a little manure turned in with the bottom spit is the best. Sowing about the third week in April is a good time for avoiding injury to their roots by the grub.

TRANSPLANTING CABBAGES (G. Tasker).—If you move them with a trowel they scarcely receive any check. We should prefer this mode; for the loosening the soil receives by digging and manuring is very promotive of growth.

MOTH IN WARDROBES (G. A. G.).—We are informed that spirit of turpentine sprinkled on sheets of paper and placed among the infested articles effectually destroys the Moth.

DISEASED EGGS (F. W. S.).—You were answered at page 192.

LAYING-OUT GARDEN (L. M.).—Nothing would induce Mr. Beaton, nor any other gardener of discretion, to lay out a garden he has never seen. He merely criticises the arrangements intended.

SOOT (A Subscriber from the Beginning).—Soot is a very useful manure for Wheat or Clover, the former, when thin of plant in the spring months, would be greatly benefited by the application of about fifty bushels per acre, sown broadcast on the land in the month of March, during dry weather. It should be harrowed in, on a still, quiet day, but in order to prevent its flying before the wind, and thereby insure a regular distribution, it is advisable to mix common salt or damp ashes with the soot. The benefit to be derived from an application of soot to Wheat will be more in the produce of straw, and its peculiar property is to induce the Wheat plant to tiller and branch out. It acts somewhat in the same manner upon the Clover plants, inducing a very luxuriant foliage. The properties of soot, as manure, may be compared to Guano, except as regards the phosphates. Your other query we are enquiring about.—J. B.

BRABMA POOTRAS.—B. P. writes to us as follows—"Many amateurs wish to know why the judges at the Metropolitan Show this month gave the prizes in the Brabma Pootra class to birds with *small combs*, similar to the Malay. That a Malay head should be put upon a Brabma Pootra fowl, which is evidently of the Shanghae race, requires a little explanation, and the poultry world ought to know the authority upon which the judges acted."

PARSNIPS (A Poultry Woman).—They will not produce roots of useful size under a plantation of laurels. Your other question will be answered next week.

PEAT CHARCOAL (L. R. Lucas).—Apply to Mr. Purser, Secretary of the London Manure Company, Bridge Street, Blackfriars.

CALENDAR FOR FEBRUARY.

FLOWER GARDEN.

ANEMONES, sow; finish planting, h. and c. ANNUALS (Tender), sow in hotbed; admit air to daily; water slightly; cover with mats the glasses at nights; sow seeds of blue and white *Campanula carpativa* in heat, for autumn-flowering, e.; pot old plants of each, and put in heat for cuttings, b.; sow *Nemophila*, and other *Californian annuals*, to flower after

autumn-sown ones; (Hardy) sow in borders, c.; for early blowing, sow in pots in a hothouse. AURICULAS, dress, and attend carefully those under glass, as the buds appear. BIENNIALS (Hardy), sow, e. BULBS, finish planting. CANNATIONS, plant, and shelter from cold winds. DAHLIAS, sow, and place tubers in hotbed, to break buds for slipping. DESS borders generally. ENGINES of Box, &c., may be planted and repaired. (See January). Cut round the roots of *evergreens*, to remove about next July. Evergreens removed last autumn may have liquid manure in fine weather. EVERGREENS, plant in mild weather, e. GRASS, roll and sweep weekly. GRAVEL, roll, and weed in dry weather, weekly, and try the *concrete* system. HEDGES (Deciduous), plant, b.; (Evergreen) plant, e. HYACINTHS, shelter, for they begin to appear. MIGNONETTE, sow in pots, and place in hotbed, or hothouse, and greenhouse, for succession. NEATNESS, attend to everywhere. PERENNIALS (Hardy), sow, e.; plant suckers, slips, and partings of roots; (Half-hardy) uncover, if frosts gone. PLANTING of flowering shrubs, complete. POLYANTHUSES, sow: earth-up with rich compost. POTTED SHRUBS, prune, shift, and dress the soil; pot off bedding geraniums, &c., from stove pots. RANUNCULUSES, finish planting, b. and e. ROSES, prune strong ones, and leave some to prune in April for late flowering; manure with cow-dung. SOWING of tree and shrub seeds, complete generally. SUPPORT, with stakes, &c., newly-planted shrubs. TULIPS, shelter as they are now appearing. TURF may be laid, and see that plants are in heat for cuttings, such as *Lobelia*, *Verbena*, &c.

Climbers, such as honeysuckles and jasmines, should be pruned and trained in the early days of the month. Reduce to moderate sized patches such plants as phloxes, asters, veronics, &c., otherwise they will occupy too much space, injure their neighbours, and harbour vermin. *Herbaceous plants* should be planted out from nursery-beds into the borders without delay. *Half-hardy shrubs*, &c., may have their shelters partially removed, closing them up at night according to the probability of the season.

GREENHOUSE:

AIR, admit freely among hard-wooded plants, such as Ericas, Epaeis, Diosma, &c., when the atmosphere is clear, and the outside temperature from 35° to 40°. In damp, foggy, or frosty weather, it is better to use little firing, and keep the house more close, unless you have the means of heating, and so far drying the air before it is admitted—the drying, of course, to take place only when the air is loaded with moisture. When the fog gets into the house, light a little fire and give air, and it will soon be dispersed. All these plants will now want more water, but do not give it in dribbles; after doing it thoroughly, wait patiently until the soil is getting dry. Those in full bloom may have similar treatment, especially if the sun will raise the house to 53°. Those swelling and opening their heads must not be lower than 45°, with 10° or 15° more in the middle of the day. AZALEAS and CAMELLIAS, place those swelling and bursting their buds in the warmest end of the house, and you may remove them to the coldest end when in bloom. Supply such rather liberally with water. Those to be retarded, keep as cool as possible, and not so moist. BULBS, CINERARIAS, and PRIMULAS, in flower, assist with manure-water; the double *Chiasse Primula* give a warm corner, as it is (especially the white) a splendid object when well grown. The night temperature of these should not be below 45°, if desired to keep them in full bloom, with 10° more in the middle of the day. *Cinerarias*, for blooming, do best at this season in small pots; those desired to make fine specimens in May and June, should not now be allowed to be pot-bound, or be stunted any way, but kept slowly growing. *Forsythia viridissima*, *Dentzia scabra*, and *Weigelia rosea* will yield their blossoms during this and the following month if slightly forced. Forced hardy shrubs keep at the warmest end of the house at first. *Begonia obliqua* makes a fine conservatory plant in winter, if the night temperature is seldom below 45°. CALCEOLARIAS and GERANIUMS, keep at the best place for light and heat. All these soft-wooded plants require more heat than the hard-wooded ones; the former shift as necessary. The forwardest of the latter, stopped and shifted before Christmas, tie out and train. Place in flowering-pots those stopped some time ago, and now breaking; and stop more young plants for succession, to be shifted when the buds have broken again. *Franciscus latifolia* and *uniflora*, do well in a conservatory at this season, if they had previously received a little extra heat, after being allowed to become deciduous in the beginning of winter, the wood being well-perfected previously. FUCSIAS, start some favourite kinds, if you can, in a nice, sweet, slight hotbed, as at this season they stand a little bottom-heat well, though, when fairly started, a medium temperature makes better plants than a high one. Cut them well down, and thin the shoots afterwards, as to many stems as you may require. The young shoots taken off, treated as cuttings in the hotbed, under a handlight, or shaded, will make choice summer and autumn plants. Repeat those for the greenhouse by the end of the month, and prune back freely; those intended for cottage windows had better remain in their winter quarters for another month, keeping them rather dry, and as cool as possible, so that more room at present may be afforded to other plants. The same HOTBED would do for *seeds*, *radishes*, &c.; and also for starting some *Achimenes*, *Gesneras*, and *Gloxinias*—the two former either in the pots by which they grew, or by removing the tubers, and placing them in pans with light earth, until they grow a little; the latter either in their late pots before they spring, or, what will do as well, in fresh pots and soil, so that, whenever they start, they take hold of the fresh material. FOR FIRES, PROTECTION, DRESSING, and CLEANING, see last month. *Insects* will now begin to be busy, and the best antidotes and sulphur vapour and tobacco fumigation, but, above all, cleanliness and good cultivation. SCARLET GERANIUMS: old plants, stored in pits, seeds, garrets, &c., examine. Remove all parts that are mouldy and damped. Dust with lime and charcoal, and expose more to the light, that the young shoots may break vigorous and strong. R. FISH.

FLORISTS' FLOWERS.

AURICULAS and **POLYANTHUSES**, proceed without delay to top-dress with rich, light, well-sweetened compost. Water them two or three times during the month, giving it only in the morning; give plenty of air on every mild day, but shut up early, and cover up securely every night, for a sudden frost would cripple the blooms. **CALCEOLARIAS**, repeat; sow seed of, keep clear of insects, and give air daily, to prevent damping-off. **CARNATIONS** and **PICOTEES**, attend to with water and plenty of air in mild weather. **CINERARIAS**, smoke frequently to destroy green fly; repeat, middle of the month; give free supplies of water to, and plenty of air. **CHRYSANTHEMUMS**, put in cuttings of, latter end. **DABIAS**, look over the roots, and remove all decayed bulbs. Set some in a warm place to start growth, and afford cuttings. **FUCHSIAS**, pot, latter end; put in cuttings of scarce sorts early, to afford good blooming plants in July. **HYACINTHS**, protect from severe weather, with hoops and mats. **PINKS**, in fine weather stir up the surface of the soil; press any that the frost may have disturbed down into the earth again. **RANUNCULUSES**, plant early in the month, choosing a dry day for that purpose. **TULIPS**, shelter from frost and heavy storms of rain, snow, or hail. **VERENAS**, look to, trim off all mouldy leaves, give water to when needed, and plenty of air every day not actually frosty. **WATER**, give to all florists' flowers in pots. Should the green fly appear, promptly destroy it by tobacco smoke. Look after **STIGS** in the frames or pits, and destroy them.

T. APFLEBY.

PLANT STOVE.

AIR, give freely on all proper occasions, but shut up early in the afternoon. **CUTTINGS** of various plants desirable to increase may be put in towards the end of the month. **DIVIDE HERBACEOUS PLANTS**, such as *Achimenes*, *Bilbergias*, *Tillandsias*, *Vrietas*, and *Hollychiums*, repeat and divide also. **IGORAS** (specimen plants), repeat; prepare young plants of, to make specimens by potting, tying-out, and giving more heat and moisture. **INSECTS**, diligently extirpate, by every means, such as cleaning the plants with a sponge, smoking with tobacco frequently, and washing the pipes with sulphur-water to destroy or keep down the red spider. **POTTING**: this is the month to go through the whole of the stock and repeat them; get batches of such things as *Achimenes*, *Gesneras*, and *Glostinias*, be potted from time to time. **WATER**, give freely as the plants grow and the days lengthen. **SOILS**, prepare for use by placing them under cover to dry and warm. **SYRINGE**: use this instrument almost daily, to give moisture to the air, and refresh and cleanse the leaves of the plants, and to keep down the red spider. Let everything be kept clean and sweet, let no decaying leaves be seen, nor moss appear on the pots or walls.

T. APFLEBY.

ORCHID HOUSE.

The season has now come when the general *potting* of the orchids will be needful. Numbers will be growing, and then is the best time of all for potting. The materials must be provided in good time, in order to be in good condition. Fibrous turves of peat, the same of loam, sphagnum or white bog moss, charcoal, and broken potsherds, are the principal articles wanted. New or well-washed pots must also be provided. The turf should be brought under cover and placed where it will become partially dry. It might be laid upon the pipes or flues for that purpose. **AIR** will, during the month, be frequently necessary. To keep the house up to the mark of *proper heat*, good fires will be necessary, and if the sun should break forth, the thermometer will run up rapidly, and then air is necessary to reduce the heat. **BLOCKS**: the plants on these will require the syringe to be used daily; refresh such plants on them as need it, with new blocks, before the plants begin to push forth. **BASKETS**, renew when necessary. If the baskets are made of wire, give fresh sphagnum, and larger baskets, if needful. **DENDROBES** will begin to show buds of bloom, give water to and repeat them as they need it. **HEAT**: the season of growth for most kind of orchids being come, the heat may be increased 10° by day, and 5° by night. **INSECTS** must be diligently destroyed. **MOISTURE IN THE AIR**, increase during the month. A dry atmosphere, now the plants are growing, will cause them to grow weak and spindly, especially *Dendrobis*: let the pipes, flues, walls, and floor be diligently wetted every day, especially in the morning. **POTTING**, proceed with without delay; if the young and tender roots push much before this is done, there is great danger of their being broken off. **Watering** at the root to plants growing must be given freely. Let all the walls, stages, shelves, window-sills, and the glass, have a *thorough cleaning*, to sweeten the air of the house. In potting, attend to the leaves and stems of the plants, sponge them well over in every part; nothing is so injurious to plants as having their breathing pores stopped with moss or dust.

T. APFLEBY.

ORCHARD.

APPLES, prune, train, and plant. **APRICOTS**, plant, train, and cover, b. **BLOSSOMS**, cover directly to *retard*. **CHERRIES**, plant, prune, train. **QUISNUTS**, plant and sow. **CURRENTS**, prune, plant, b. **CUTTINGS** of all fruits, plant, b. **DRESSING**, carry out of all borders; beware of the spade. **FILBERTS**, plant; hang catkins, and remove suckers. **GOOSEBERRIES**, prune, plant, train. **GRAFTS**, collect immediately; put them in a cold corner; in May commence operations at, c. **LAYERS**, make. **NECTARINES**, plant, b. **MOSS**, remove; use brine. **MULBERRIES**, plant. **NECTARINES**, plant, prune, train. **ORCHARD-TREES**, finish planting and pruning; top-dress old ones. **PEACHES**, as *Nectarines*; apply sulphur and lime wash. **PLUMS**, plant, prune, train. **PEARS**, plant, prune, train. **QUINCES**, plant. **RASPBERRIES**, plant,

prune, tie. **SUCKERS**, remove from all fruits. **VINES**, plant, prune, train. **WALNUTS**, plant and sow. Watch for the scale, aphides, and other insects, and try to utterly exterminate them. R. FRINGTON.

FORCING HOUSE.

AIR, admit on all occasions, if safe. **APRICOTS**: see *Peach*. **CUCUMBERS**, keep good linings to dung-beds; sprinkle bed often; air frequently; bottom-heat 90° maximum. In houses, train regularly, stop occasionally, and give liquid manure, with a moist air heat of 70° to 80°. **CHERRIES** as *Peaches*, only a lower maximum—say 70° sun heat. **CAP-SICUMS** and **CHILIES**, sow, b. **FIGS** as *Peaches*, only a higher minimum—say 60°. **GRAPES**, late, keep dry and cool; thin the berries. **HEAT**, in all cases, in proportion to, and advancing with, light. **KIDNEY-BEANS**, 65° to 70°; plenty of air, moisture, and a light situation. **MELONS**, sow; provide beds, &c.; air-heat, 70° to 80°; bottom-heat, 90° maximum. **MOISTURE**, constantly provide the air with, wherever fire-heat is used. **NECTARINES** as *Peaches*. **PINES** *Fruiters*, rising, increase warmth and air moisture; liquid-manure to the roots occasionally; (*Successions*) still dry if in dung-pits. **PEACHES**, disbud, and pinch; cross shoots; fumigate occasionally. **POTATOES**, get out successions. **STRAWBERRIES**, introduce plenty; keep moist air, frequent ventilations near glass; maximum 65°. **TOMATOES**, sow, b. **VENTILATION**, night and day, as long as air, moisture, and heat is secured. **VINES**, disbud early, and attend to thinning the berry; keep clear of all waste spray. Keep a mellow state of air, neither damp nor dry, but a permanency of air moisture. **WATERING**, attend to with regularity and precision. R. FRINGTON.

KITCHEN GARDEN.

ARTICHOKEs, defend from frost. **ASPARAGUS**, plant in hotbed, and attend to that forcing. **BALM**, plant. **BEANS**, plant; earth-stir, and transplant from frames, c. **BEETS**, sow a little for early use; plant for seed, and dig up for storing any left in the bed. **BROCCOLE**, sow, c. **BROCCOLI**, sow a little, c. **BURNET**, sow or plant. **CAVEAGES**, plant; sow; and plant for seed. **CABBETS**, sow on gentle hotbed for early use; attend early to thinning advancing crops, &c.; plant for seed, c. **CAULIFLOWERS**, attend to, airing, earth-stirring, removing all decayed leaves and slugs; plant out winter standing, should the weather be open and mild, and attend to spring-sown crops (see last month); sow, if required; prick out. **CELERY**, attend to earthing-up, protection, &c.; leave for seed, and sow a little for early use. **CHEFVIL**, sow. **CHIVES**, divide and plant out. **CLARY**, sow, c. **COMPOSTS**, prepare and turn over. **CORIANDER**, sow. **CORN-SALAD**, sow. **CUCUMBERS**, attend to those forcing; prick and plant out; and sow in hotbeds. **DILL**, sow, m. **DUNG**, prepare for hotbeds. **EARTHING-UP**, perform when necessary. **ENDIVE**, still protect from wet and severe weather. **FENNEL**, sow or plant. **GARLIC**, plant. **HORSE-RADISH**, plant. **JERUSALEM ARTICHOKEs**, plant. **KIDNEY BEANS**, sow in succession, &c. Keep a good supply of **EARTHS** in the dry for immediate use. **LEEKs**, plant for seed; sow, c. **LETTUCES**, plant out from frames, &c., of the winter standing, towards the end of the month, and sow in the open border. If short of plants, sow in frames on a gentle hotbed at the beginning of the month. **LICORICE**, plant and dig up. **MELONS**, plant out for early crops; sow and pot off; attend to this sort of work on a kindly calm afternoon, just before shutting-up time. **MINT**, force, in hotbed; plant. **MUSHROOM-BEDS**, make in succession, and attend to those in bearing. **MUSTARD** and **CRESS**, sow in succession. **ONIONS**, sow main crop towards the middle to the end of the month; also plant for seed, if not done; and plant the Underground or Potato Onion. **PARSNIPS**, take up where left in the ground till now; plant or leave for seed; also sow towards the middle of the month, particularly in light soils. **PARSLEY**, sow. **PEAS**, sowings may be made both of early and second on the same day, where the soil works well, as the one will be found a good succession to the other at picking time; also to suit some unfavourable situations, it is well to sow in frames in small pots, or in sods of turf, which is by some thought best, to plant out when a good season offers; also attend to sticking, earthing-up, and protecting other forward crops. **PENNYROYAL**, plant, c. **POTATOES**, plant in hotbed of any favourite early kinds; this may be done from the first to the end of the month; also plant out during this month all the main crops, if the soil will admit of it, and plant whole sets in preference to cut ones; also look over those in store, often to keep shoots rubbed off. **RADISHES**, attend to (see January), and sow in succession either in border or hotbed. **RAPE** (for salading), sow; (*Edible-rooted*), sow. **RHUBARB**, sow in large pans, or open warm border, and attend to that forcing, either indoors, or cover up with pots, or tubs, and fermenting materials. **SAGE** and **SAVORY**, plant, c. **SALSIFY**, sow, c., in small quantity, for early use. **SAVOYS**, sow, m. and c. **SCORZONERA**, sow, c., in small quantity, for early use. **SEA-KALE**, attend to that forcing; cover up in succession. **SHALOTS**, plant. **SKIRRETS**, sow, c. **SPINACH**, weed, sow, m. **SORRELS**, sow or plant, c. **TANSY**, **THYME**, and **TARRAGON**, plant, c. **TURNIPS**, plant for seed; sow, c. **VACANT GROUND**, dig; weed, &c. There is a right time and a right way of doing everything. Plant out in mild, open weather; wheel out manure, &c. on frosty mornings, or on a fine, dry day; make good use of the hoe on fine, dry days, in stirring among the various crops; look over all in-door stores in rainy weather; and tie the ends of new mats before they are applied to use.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 45.3° and 32.6° respectively. The greatest heat, 57°, occurred on the 3rd in 1850; and the lowest cold, 10°, on the 5th in 1830. During the period 94 days were fine, and on 95 rain fell.

It ought to have been stated in the first paper on THE GARDEN PEA (page 314), that much allowance is to be made for trials made during the last season, in consequence of the extremely wet and ungenial state of the weather during the summer months. In favourable summers, the period of growth, that is, the time occupied between the sowing and gathering, is some days less than indicated in those observations; thus, in a warm summer, *Taylor's Prolific*, and *Sangster's Number One*, would have been at least four or five days earlier. We come now to notice one of the most distinct and characteristic Peas in cultivation.

DANECROFT RIVAL.

SYNONYMES.—*Glass Pea*, *Girling's Pea*, *Girling's Danecroft*.

This variety is readily distinguished from all others by the peculiarity of the colour of the whole plant, which, instead of being of a dark or lively greyish-green, is of a pale and sickly-looking yellowish-green, or rather greenish-yellow. This is not occasioned by any unhealthiness or want of vigour in the plant, but from the absence of that secretion which is met with on the leaves of other Peas, or those of Cabbages, and on the fruit of Plums and Grapes, commonly called *bloom*, and which, by some of the learned, is said to be wax, and by others, resin.

The plant is from two-and-a-half to three feet high, of slender habit of growth, and consists of a simple stem. The pods are produced singly, and are from two-and-a-half, to, sometimes, three inches in length, perfectly straight, and terminated abruptly at the end; being in every respect similar to those of *Warner's Emperor*. They contain, on an average, seven peas, but occasionally eight. The ripe seed is white. It was sown on the 5th of April, bloomed on the 5th of June, and on the 14th the blooms dropped, and the slats appeared. On the 2nd of July the pods were quite filled and ready to be gathered. This, though an early Pea, and coming in almost as soon as any of those already described, is not a desirable variety for general cultivation. It is much less productive, and considerably more tender, as the gardener who trusts to it for his first crop will soon discover to his cost and disappointment. It was raised some years ago by Mr. Girling (Girling of Danecroft, near Stowmarket), in the days when there were no *Number One* nor *Emperors*, but now it is not worth cultivating except by the curious.

BECK'S GEM.

This is a real gem—a horticultural gem. It is not above a foot high, and completely covered with pods. For small or private gardens, or for forcing, this will be a most valuable acquisition, as it occupies comparatively little space, and produces as great an abundance of pods as many of the varieties do which require sticks. It is but newly introduced by Messrs. Beck, Henderson, and Co., of the Adelphi, London, from whom I procured it.

The plant is one foot high, of a stout habit of growth for its size, and consists of a very short-jointed stem,

which branches at almost every joint from the base to within three or four of the top, and produces from fourteen to eighteen pods. The pods are almost always in pairs, rarely single, and are produced at every joint, particularly towards the top. They are about three inches long, six-tenths of an inch broad, perfectly straight, somewhat waved on the upper side, and tapering gradually at the point on the under side. They are smooth, and of a dark green colour, plump, and well-filled, containing from five to seven peas, which are as large as those of the *Imperial*, being nine-twentieths, or nearly half-an-inch long, seven-twentieths broad, and the same in thickness. The ripe seed is somewhat ovate, and of a greyish-pearly colour.

The seed was sown on the 5th of April, and the plants bloomed on the 7th of June; on the 12th the blooms began to drop, and the slats appear.

On the 25th the plants ceased blooming, the first pods were ready for gathering on the 2nd of July, and a succession was kept up till the 24th of July, by the same plants.

This is one of the instances which reconciles us to the increase of the number of varieties. But that we may fully appreciate the value of such introduction, our first consideration should be the total extinction of all such varieties as are found to be inferior in value, and, consequently, worthless.

We have now completed what may be called the earliest Peas, and from what we have stated, it will be

seen that there is very little difference as regards the time at which each is ready for gathering. Still, however, although the number enumerated is small, there is room for selection, and for the earliest crop we would recommend either *Taylor's Prolific*, or *Sangster's Number*

One, and *Beck's Gem*. Any of these, if sown in a warm situation early in January, will, if all goes well, produce an abundant crop in the second or third week in May.

R. H.

(To be continued.)

CONTINUING our notes on "The Plants of the Bible," we come next to THE ALMOND.

We are justified in concluding that the ALMOND is not a native of Palestine, because, when Jacob wished a suitable present to be presented to the Egyptian ruler, he desired that *Almonds* might form a part of the gift as being "of the best fruits of the land" (*Gen. xliii. 11*). Now, such fruits are esteemed to be those which require some care in the culture. We should not consider Sloes and Crab Apples "of the best fruits" of England. The Almond grows wild in Barbary, but its fruit is very inferior to that obtained from the cultivated trees in Palestine and other parts of the Levant. In commerce they still retain the name of the *Jordan* Almond, but they are no longer exported hither from the banks of that river, our supply being now chiefly derived from the south of Europe.

The regard and attention paid by the Israelites to this tree and its fruit is strongly evidenced by the various allusions to it made in the Holy Scriptures. These allusions are nearly all, in some mode or other, founded upon the earliness of its blossoms.

Theophrastus, who wrote about three hundred years before the birth of our Saviour, remarks that it was the only tree in Greece which produced its blossoms before its leaves. We all know that such is its habit in our own shrubberies, and that those blossoms are among the earliest that adorn the spring. It was on this account that God employed it as an emblem to denote how speedily his judgments should be executed upon Israel. "Jeremiah, what seest thou?" was God's question to the entranced prophet; and when he replied, "I see a rod of an Almond Tree," God rejoined, "Thou hast well seen, for I will hasten my word to perform it" (*Jerem. i. 11, 12*).

For a similar reason, probably, was Aaron's rod, or official staff, formed of a branch of this tree. It was well calculated to remind its bearer of the promptitude and early devotion to his duties required of him by God. Nor was the lesson less impressive upon the people, for when they saw that the rod budded, blossomed, and bore Almonds in rapid succession, it urged upon them that the good thoughts of the heart, if unchecked, give rapid birth to suitable efforts and results (*Numbers xvii. 8*).

As teaching these lessons—as a symbol that "the best fruits" of our lives and the first thoughts of our hearts should be towards God—Almonds were, perhaps, selected as a happy symbolical form for the bowls of the lamps, or candlesticks, of the Temple. Such offerings of our best and earliest would be a light to the Temple, and upon such offerings would the light of the Temple specially descend.

Lastly, it is elegantly used by Solomon as a symbol of advancing old age, when he says "the Almond Tree shall shed its flowers" (*Ecclesiastes xii. 5*).^{*} Man was justly compared to an Almond Tree, because, as he becomes wise by experience, so this tree becomes more fruitful as it advances in years; a fact well known to the ancients, for Pliny says, "The Almond and the Pear are in their old age most fruitful" (*Nat. Hist. l. xvi. c. 27*). So also is extreme old age as beautifully compared to an Almond Tree casting off its flowers. With us the Almond has pink blossoms, but in the east the flowers are snowy white, and a fitting simile of those white locks the falling off of which has ever been named as a symptom of extreme length of years. It is not only alluded to in our own sonneteers well-known words—

"Time hath thinned my flowing locks,
The few I've left are grey;"

but Anacreon wrote long before from the lands of the East—

"Oft am I by woman told,
Poor Anacreon, thou grow'st old:
Look how thy hairs are falling all!
Poor Anacreon! how they fall!"

In the *Malvern* Prize-list for the present year, which announces the Exhibition of that Poultry Society for the 13th and 14th of September next, we find the classes almost entirely confined to Chickens, Dorkings and Bantams being the only exceptions where the seniors are permitted to enter the lists. Considering the time of year at which the birds will have to make their appearance, the limitation to those hatched in the year is certainly a wise restriction, though we are at a loss to understand why Dorkings alone of the larger fowls should be exempt from this arrangement. With four separate classes for Shanghaes, could not the Committee have given one each to the Coloured and White Dorkings? Hardly any two varieties of any breed are less suited for a common class, and we cannot but regret to see it in this instance. A new division, again, of Game Fowls is also proposed, for *Duckwings and Black-breasted* are to go together, the rest in a common medley. We hold this to be a great mistake, for it would be difficult to take any two varieties of the Game Fowls more distinct in feather than the black-breasted "reds" and the Duckwings. But this word "red" is an insertion of our own, for we presume its omission to have been accidental in the list before us, since "black-breasted" is a term by which alone no variety of game or other fowls has yet been distinguished. But what becomes, may we ask, of the remaining "reds," the

* The Septuagint and our version of the Bible interpret it, "The Almond Tree shall flourish;" but Parkinson justly remarks that the Hebrew "never has anything like this meaning elsewhere in the Hebrew Bible."

"gingers," and "streaky-breasted" among others? Surely they should stand with their black-breasted relatives on every account, the position, in fact, which invariably they occupy where the Game Fowls receive the greatest care in the sub division of the various members of their family. If it be said that the heading of Class 8 should have been "*Black-breasted, and other reds, and Duck-wings,*" and that the meaning is apparent, all we reply is, that Secretaries should be more accurate in the correction of their published prize-lists, if they wish to avoid the inconvenience and confusion of which we have very recently had occasion to complain.

The high rate of pen-money, four shillings for each, as also the unusual charge of 10 per cent. on all sales, lead us to imagine that this Exhibition is designed to be self-supporting; and since this is undoubtedly the footing on which the permanent stability of all such institutions should be founded, we shall gladly hear of its success in the present case; and if the number of pens prove somewhat more limited, the counter-balancing effect of the exclusion of much rubbish must be taken into favourable consideration.

In one respect the decision of the Malvern Committee may be followed profitably by those with whom may rest the arrangements for other Poultry Societies during the ensuing season. Two days are wisely fixed for the duration of the Show, a private view being given on the afternoon of the judging-day. The hour, also, for closing on the second day being 6 p.m., a majority of their birds may be on their homeward journey that same evening. Under certain circumstances, where more than ordinary expense is unavoidable, the extension to a third day, as we have often said, may be reasonable; but, beyond this, we reiterate our conviction, that no further period of confinement for the fowls should be permitted. Dead, dying, and sickly specimens, but which had been placed in their several pens in perfect condition and health, have but too often appeared on the opening of the returned baskets, and such must inevitably continue the result of these unduly protracted exhibitions.

The absence of the name of a gentleman (whose triumphs in the Dorking and Spanish classes may be almost termed uninterrupted for the last two seasons) from the list of awards at the late Metropolitan Exhibition is thus to be accounted for. Captain Hornby, indeed, has suffered too severely from the evils we have now spoken of to subject his birds to the eight or nine day's confinement that their appearance at Baker Street must have entailed, and he is, moreover, far from standing alone in this determination, so that a fourth day, we hope and trust, will rarely again mar the pleasure and satisfaction of any Poultry Show whatever.

CULTURE OF TOMATOES.

It happens of necessity that the departmental writers in THE COTTAGE GARDENER occasionally cross each other's tracks; this I take to be more contributory to the cause of truth, and the well-clearing-up of questions,

than if each were to observe a most rigid line of demarcation, which would merely produce and spread one set of opinions, in which the unknown are but too apt to build up a set of cut-and-dry rules, which, however right in themselves, cannot with sufficient pliancy adapt themselves to awkward circumstances. This it is which renders the gardeners of the present day so immeasurably superior to their predecessors; they are compelled to carry out about double the amount of business with the same number of hands, or, as I know in many cases, with a less number, and this cannot, like the vast impetus given to commercial matters in later years, be attributed to the introduction of steam power.

The *Tomato* is an instance of what I urged at the commencement of these remarks; its culture has been written over and over again; but, indeed, of what branch of the gardening art, or of what individual thing within its precincts, may not the same be said? This singular plant is a puzzle, in our fitful climate, in more ways than one. Except in more favoured southern counties, it requires the aid of a wall, and one, too, with a southern aspect; but since the growing increase of our tender Pears, and the still-existing demands for sites on such aspects for our good old fruits of proved character, gardeners find it most difficult,—shall I not say impossible?—to suit all these customers. What, then, may give way? Here is the rub! Who will give up his Moorpark Apricots; his Royal George, Noblesse, and Galande Peaches; his Elruge, Newington, and other Nectarines; to say nothing of Neils Pears, or the D'Arembergs, Passe Colmars, &c., with a very early Duke Cherry, and several others I could name?

I well remember, that many years since Mr. Loudon quoted some *Tomato* culture in his Magazine, which, at the time, appeared singular, because uncommon. The gist of the plan was the keeping the plants, from year to year, as perennials, or rather, in the language of botanists, as suffruticose shrubs. This, of course, implies that they were kept in a heat congenial to their habits, and they were, indeed, preserved in hot stoves. Fruit was, of course, in use through the whole winter, and, indeed, nearly all the year; and I advert to this fact, merely to show those of our readers, who are not very knowing in horticultural matters, what the real habits of the plant are, and in so doing, lead them to approach as near those conditions as expedients within reach will permit.

The ordinary practice in this country is to treat it as a half-hardy annual; few can afford house room for it, except during the nursing season in a young state, and then its treatment, as to temperature, light, &c., may be lumped with such things as the Capsicums, Chilies, and, if you will, the ridge Cucumbers. But there are a few *special matters* to which I would point, and these deserving of consideration by those who are desirous of enjoying the luxury of good *Tomato* sauce; and to those who are as yet unacquainted with this powerful and peculiar zest, to say nothing of Soyer's fancy *Tomato* dishes, I would say, just try a little really good with a first-rate rump steak when the appetite is thoroughly whetted with several hours' keen exercise.

The first thing I would name, then, is, that those who cannot afford all the necessary appliances of heat, &c., place their plants in such a condition at the beginning of summer as to be ripe for action, that is to say, be so mature in habit as to possess a tendency to blossom rather than a profusion of leaves. To accomplish this, the best plan I am acquainted with is to sow in October.

Strange advice, some of our country cousins will say; and so it is; but let us show why it is expedient. Of course, this pre-supposes the having a house or pit artificially heated to fly to: without that I urge nothing. Sow in October, then, in a plain, loamy soil—mannrial matters unknown. The reasons for this strange course

shall appear in their place. When the plants are fit to handle, plant a few in five-inch pots singly, there to endure the winter; when they are about five inches high let the terminal point be pinched—this will bring us to about the second week in November, and by this time the pots will be filled with their fibres; and such being in reality the case, they will be in a position to endure a good deal of dryness, which, as a winter procedure, is essential. And now, until April, all that they need will be a situation in some house, pit, or frame, where they will enjoy from 50° to 55° through the winter, and as much light as can be afforded them.

By the end of this period it will be found, under such treatment, that they are somewhat of what gardeners term a woody character, rather than such a soft, plant, and watery annual as we too often find them by ordinary culture.

But, be it observed, let them be kept, as to watering, in a niggardly way all this time; they must scarcely be permitted to grow, only to keep the first-formed leaves tolerably fresh. In the axils of those few simple leaves lay the germs of shoots already in a latent way ripe for development, only waiting better skies; perhaps we might, in this case, borrow a phrase from nautical men, and say, "lying-to under bare poles," which may be translated—"waiting in a patient position for favourable circumstances." And if our warm-blooded seamen may be allowed to be occasionally quiescent, surely a gardener may; and if such is followed by a proper course of action it will prove that such plans, although at the moment inexplicable, were not matters of mere whim.

And now we have our little half-shrubby Tomato plants brought to the middle of April, by which time they will be about ten inches in height, and possessing one main stem only, so hard in texture as to require no support, and to stand any breeze. The terminal point should have the first blossoms formed, and the plants should now be well hardened off, keeping them still within some structure, or cold frame, or pit, close to the glass, and where they will enjoy a puff of wind occasionally.

I may here observe, that they should be grown up to this time entirely in a sound loam, not a particle of anything else with it. This I recommend *strenuously*; and I may as well show why. If they were grown in any light mixture rich in humus, they would grow too fast to solidify, they would require watering frequently, and the whole plant would be thrown into a false position. Now, my object is to make the solidification of the stem, &c., keep pace with the growth; and if in strong loam they will go for weeks *without water*; and this it is which makes them such sound plants.

Those who plant them against walls will be enabled to get such plants out about the middle of May; indeed, they must about follow the rules of the "bedding-system," and they should be planted *on the ground-level*, or rather above it. This is most important, in order to avoid over-luxuriance, which is the bane of the Tomato in our climate, nine cases out of ten. As for the soil they are filled up with, that matters little, so that it be rather light; and henceforth their culture is pretty well known. I may here observe, however, that we seldom use shreds in nailing them; we just drive the nail through the centre of the stem—a rough procedure, certainly, but this is rather a benefit than otherwise, as it, doubtless, administers a wholesome degree of punishment to these proud revellers in the damp air of our British skies. If the summer prove congenial, they will, despite these precautions, run too much into a rampant foliage, and this must be occasionally reduced by cutting some of the big leaders half away, and by destroying every sucker and superfluous side-shoot betimes; and in addition, they must have one or two

root-prunings; being in an elevated position, this is easily accomplished by just thrusting down the spade parallel with the wall, at about a foot distance, and cutting through every root. The worst pest, now-a-days, is the Potato fungus: this has taken possession of the Tomato, and no marvel either, being of the same family. There can be little question, I think, about its identity: certain it is, however, that this odd plant has become liable to a pest of the kind; and I have found sulphur a great check to it. I have not half-exhausted the Tomato subject; there are other phases under which to view its culture, and I may have to return to it.

R. ERRINGTON.

MEETING OF THE HORTICULTURAL SOCIETY.—JANUARY 17, 1854.

We do not expect to see much of gardening at these meetings in the middle of January in any year, and less after so hard a winter as we have just experienced. Nevertheless, we had some rare things to look at and to think about, besides some excellent fruit and flowers. The rarest thing that I have yet seen at the Regent-street Meetings was a bunch of the *Luculia gratissima* in flower; not from the lower ranges of the Himalayas, its native place, but from the open air in Devonshire. Fifteen years back, it was not unusual to meet with this plant, at Christmas, in flower in the stoves about London, not so good-looking as the one from Devonshire, it is true, but still in bloom, and sweeter than a violet; confined heat, or any degree of forcing, except for a month or so when it starts in the spring, being next thing to death to it. This rare experiment was tried, and succeeded, in the garden of J. Luscombe, Esq., of Combe Royal, near Kingsbridge, South Devon. The plant stands out there trained against an east wall. I suppose the wall of the dwelling-house, for there is a fire on the other side of the wall, and the heat from it, was greatly in favour of the *Luculia* outside; in addition to this, "a ragged mat" was placed over it in cold weather; and in the coldest time, when the thermometer was down to zero about London, they placed a frame of rough boards in addition; that was all the protection that this plant ever received there; and here we had a sample from it in bloom in the middle of January. Mr. Luscombe grows Oranges and Lemons against the common walls of his kitchen-garden just with the same kind of protection, and sends up specimens of them every year to the Horticultural Society. In a general way, the *Luculia gratissima* requires the same kind of winter protection and management as the tree Rhododendron; and as it is the sweetest plant in the world, I mean the flowers, and never refuses to bloom in winter when it gets the right treatment, I should like to hear Mr. Fish say all that can be said about it, so as to get it into general cultivation. I once had three dozens of them, and I had orders to pack one, four feet high, in full bloom, for her Majesty, and the Queen is so fond of it, that a stock of it is kept up in the royal gardens ever since.

Mr. Luscombe sent also, from the open air, cut specimens of the old *Linum tigrinum*, one of the very best of all the good old winter flowering plants. When this plant is done well it is little behind the *Allamanda cathartica* in beauty, as was plain enough from a plant sent from the garden of the Society to this meeting. This plant was not quite a yard high, but it was in full bloom all over, and every flower was as broad as a shilling, and as yellow as a butter-cup, and about the same tint. Perhaps I can tell as much about this plant as anybody, for I had once a plant of it as tall as a man, and quite as full of bloom as the one from the Society, and it kept so for full four of the dullest months. The treatment was peculiar, and few gardeners have yet hit

upon it; but here it is. The plant was five years old, and if it had been three times older it would be still finer, for I believe any age under twenty years is young enough for this plant if it is managed properly. First of all, it comes from cuttings as freely as a Geranium, and March is the best time to make them. It cannot endure in-door culture in the height of summer, owing to its liability to the attacks of the red spider; therefore, a cutting struck in the spring, and kept in a damp, hot frame till the middle of May, is then turned into a close, cold pit, where it stands till the beginning of July, and where it is kept very damp all the time to keep the spider at bay. It is then planted out in a very warm, sheltered corner, but not against a south wall. The soil here cannot be made too rich for it, and it must be a light compost; to encourage the roots to the surface, and to create a damp atmosphere round it, a thick layer of fresh moss is placed over the surface as a mulching; and to the end of August, or at all times while the weather is hot, this moss is syringed over, whether the roots need water or not, all this damp being absolutely necessary to save it from the red spider. As soon as the plant begins a fresh growth after being turned out, it is stopped, to cause it to become bushy; ten inches or a foot is long enough before stopping, as the plant is naturally inclined to grow tall in the free soil. A little frost will not hurt it here, but it ought to be taken up early in October, potted, and put in the shade under a mat, for three weeks; by that time it has taken to the pot, and may be set in the greenhouse, or cold pit, till about Christmas, when, if it is intended for a very fine specimen, it ought to be put into a cool stove, say in a heat of from 50° to 60°; here it will ripen the wood made last autumn, and also produce many flowers; and in March it is allowed to get so dry, by degrees, that the leaves droop and fall off, and by the end of the month, or early in April, it is pruned very close, every side-shoot down to the last eye, and a few of the strongest to six or nine inches. It soon pushes again, is then shaken out of the soil, the roots much cut back, is put into the smallest pot that will hold the roots, kept close for a little while, and out again to the close pit, as last season, planted out, taken up, stoved in winter, dried, out, and potted, as before. The third winter it is fit to be seen, and would take no hurt in the drawing-room for two months, or in a cooler place, if needs be; wintering in the stove is not absolutely necessary; but I cannot see how a really superb specimen could be made without it in less than five or six years. Yet it is a hardy greenhouse plant, and it has stood out against a wall in South Devon this hard winter with only a slight protection.

There was a singularly pretty plant from the Society's garden, called *Thyracanthus rutilans*, one of the soft-wooded Acanthads, coming near to the *Justicia* in growth; it might be nearly a yard high; a single stem, as like the old *Justicia coccinea* as anything could be in look and growth; from the top of this, spread out and hung down half-way to the pot, slender flower-spikes, or thyrses, just like long whips of *Russelia juncea*, and these were loaded with the brightest crimson tubular flowers, about twice the size of those of the *Russelia*, and hanging down the same way. At a venture, I should say, that the best way to get this ready for Christmas Shows would be by taking an early spring cutting from a top branch, striking each in a separate pot; good, strong hotbed culture, as long as there was head-room for it; not to be too hasty in shifting, but liquid-manure to make up for pot room, as the plant ought to flower in a number 24-pot as the largest size; to keep the plant very near the glass in strong, moist heat till the end of August; after that, drier and drier by degrees, till a dead stop was put to farther growth; and as soon as the tops of the flower-strings, so to call

them, appeared, heat and moisture to be resumed; at any rate, it is a nice thing, and certainly requires some care in the management to bring it out as perfect as it is capable of being done.

Selago distans is another plant which the Society exhibits every winter, and a better plant of it than the one sent to-day was never seen; not a leaf on it could be seen; it was one mass of pure white spikes, like white Mignonette, if there was such a thing, full four feet across, and not two feet high. I shall not attempt to say how this has been done, for, to tell the truth, I do not know how; but I know that these simple and soft-wooded plants require more daily attention during every stage of growth than the rarest Heaths, and that it is only after many year's close attention to their requirements that any one can excel in their flowering. There is a great deal more care necessary to make a fine pot specimen of a common *Petunia*, or a common *Verbena*, than there is for getting a *Queen Pine-Apple* up to six or seven pounds; but, of course, no one but a gardener is aware of this, and any one but an old gardener, who ventured to say as much, would be hooted out of countenance: it is a fact, for all that. There is nothing like driving at facts, be they ever so common or so unpleasant at the time. I have been hammering for years at the execrable, puny, half-starved, and shameful plants they grow about London, of that most beautiful of all beautiful-leaved plants, when done well, the *Gesnera zebрина*. Some people in the country think that I durst not show my face to London gardeners for my hard sayings; quite the reverse; they are all glad to see me. They know much better than I can tell them when they are behind; but the best of us cannot always be up to the mark in every thing, and it often happens that a soft-headed fellow in the country hits upon a thing by mere chance which puzzles the best brains to find out by the closest experiments and daily toil; and yet there are gardeners, and masters too, who think that it is only necessary to be a gardener for knowing everything that way all at once.

A really well grown specimen of the *Gesnera zebрина* has been cultivated and exhibited from near London at last; we had it here to-day from the Society's garden, four plants in a No. 16 pot, all of the same size and tints in the leaves, about a yard high, and the leaves hanging over the pot, the flower-spikes strong and in full bloom. The great art in growing this plant is to keep all the leaves in full beauty to the very last, whether the plant is tall or dwarf, and as the leaves are so handsome, the taller the plant the more leaves, and consequently the more beauty. A single plant of it, though grown ever so well, does not look nearly so handsome as three, four, or five. I like five best in one pot, the middle one to be a little taller than the rest; but a No. 12-pot would be necessary for such a specimen. The way to make it sure and easiest would be to grow each plant in a separate pot till the flower-bud appeared, then to put the five in one large pot at once, either keeping the tallest for the middle, or planting the other four a little deeper. Another advantage of growing them in single pots to this stage is, that if they are a little too long in the legs you can plant them so deep in the big pots as to bring down the leaves to the very edge of the pot at once; but in that case the big pot should not be filled up with the compost at once, only a little now and then, just as the new roots from below, or from the naked stems, filled the last earthing up; the way they often do with forced Kidney Beans.

The finest sight I ever saw of these *Zebribinas* was last year with Mr. Barley, the gardener at Newnham Courtney, near Oxford; he had a whole house full of them just set for bloom, and in their large pots, as here described, and there was not a single bad leaf in the house; the darker-leaved variety, and the one called

Herbertii, with a greener leaf, were never seen more perfectly to differ from the ordinary kind. There were six kinds of *Corraus*—*speciosa*, *Goodii*, *pieta*, and *pieta superba*, *curiosa*, and something else, all like so many Fuchsias in bloom. A fine plant of *Acacia linifolia*, one of the earliest and the best to make a close specimen of the whole family, with a brilliant *Epacris*, called *ardentissima*; all from the same collection.

Mr. Jackson, of Kingston, my next door neighbour, sent three beautiful *Orchids*, for which he got a smart prize; the newest of them was a strong plant of *Warrea Lindeniana*, a ground Orchid, from somewhere about the Spanish Main, on the north-east side of South America, where it was discovered by Mr. Linden, a foreigner, after whom it is called. It had a flower-spike above two feet long, quite upright, and carrying fifteen or sixteen flowers, which are all of a creamy colour, except the lip, which is of a rich reddish-purple. It seems to be as fit for winter work as the old *Phaius grandiflorus*, and requires exactly the same treatment, so that it is everybody's plant who has heat at command. The second was a large mass of *Barkeria Skinnerii major*, the dark crimson variety; this, and the older light crimson *Skinnerii*, have been in bloom with him all this winter, hanging in dozens, from close to the roof glass along the whole north side of the Mexican, or cool house, where I often go to see them on purpose, and am quite sure that all these *Barkerias* are much easier to grow and to keep than fancy *Geraniums*; and that the reason why some gardeners fail with *spectabilis*, is by giving it too much heat; it should never be above 60° any day in the year, if it could be kept so low; a cool greenhouse is much too hot for it in summer. When Mr. Skinner first sent it home, he said it ought to be out-of-doors all summer, hanging from a tree over a brook, or pond; and a pupil of mine, who knew this, is the only one who has yet brought it out in full perfection; I mean Mr. Brewster, gardener to Mrs Wray, at Cheltenham. It seems to me that the very rare *Barkeria elegans* is just like it, and I know that the least over-heating will tumble it heels over head. They have a large stock of it at Kingston; and one fine plant coming into flower, I was very anxious they would get ready for this show, but I warned them about the degree of heat it could stand. Who would take heed to what an old gardener could know about Orchids, however. Not they, indeed! So this lovely Orchid was put into the Calcutta-house to get it up in time for the meeting. Mark the result: every one of the flower-buds dropped off the third or fourth day; and, as I told them, it served them just right enough; but as they have plenty of it, I hope we shall see one at the next meeting, or at some one of these meetings in the spring. The third was a good blush variety of the *Lycaste Skinnerii*, a plant that runs into a great number of shades and sizes in the flower and footstalks.

Talking of the next meeting reminds me that we were promised a sight of the wonder of the age at that meeting—that is, drawings and dried specimens of the largest tree on the face of the earth—a bigger tree than the Boabab itself, and as tall as four of it, if reports are true. This is quite a new thing, and is called after the first Duke of Wellington, *Wellingtonia gigantea*, a kind of conifer, an evergreen, and as hardy as the Scotch Pine. Mr. Lobb brought home seeds of it lately to Mr. Veitch from far away in the mountains above California; seedlings of it are up, and doing as well as can be expected. I saw two or three of the cones, and I am quite satisfied that no other Conifer cones in the same way. The nearest that I could liken it to was a little abortive cone, which a friend brought me from the old Cedar trees on Lebanon. We had just a glimpse of a small drawing of this *Wellingtonia* at the Meeting, with a likeness of a man under it, to show the relative heights.

but I should not like to be made a picture of for such a purpose when I was full grown, for the huge tree makes the man look no bigger than Tom Thumb.

There was a large assortment of *Sabal plants*, as good as any family could wish for, from Celery to French Sorrel, from the Society's garden, but they still keep to the French names, and for Lettuce you have a name like *latitude*; and Sorrel is *Gazelle*, or some such confounded name, and so on until you forget the very names of the commonest things you ever planted, parted, or sowed the seeds of; and all this nonsense for no other earthly purpose but to make believe that the things are new to all the world, except the world of this Society.

PEARS.—Of these there were abundance of winter desert ones, and not one of them fit for the table, except *Ne plus Meuris*, just turning colour, a most awkward Pear to dish well, and not very tempting to look at, but a most delicious Pear when you break into it, if it is in the right state; a most easy tree to manage, as it grows stubby, and a good, sure bearer.

PINE APPLES.—Of these we had only one, and that from one of the best Pine growers in England, Mr. Jones, gardener to Lady Charlotte Guest, Dowlais, Glamorganshire. It was a *Queen Pine*, with a very small crown, as Mr. Fleming grows them, who told me, last summer, that the only secret in having small crowns is to keep air on the pits all night throughout the year. This *Queen* was only 3 lb. 7 oz., but it was grown as an experiment, and sent to London to shew the result of that experiment. It was as fine of that size as ever was seen; it was grown in a 10-inch pot, to keep the plant small, and economise space, and peat was the compost. Now, if Mr. Jones can cut a hundred pounds of *Queen Pines* from a pit that would only produce eighty or ninety pounds of seven-pounders, his plan is by far the more economical; and a party of eighteen to dinner seldom eat a three-pound *Queen* at one dessert, as these *Queens* are much larger than black Pines of the same weight.

STRAWBERRIES.—There was a nice dish of forced *Black Prince*, from Mr. Brown, gardener to J. Darnell, Esq., of Waltham Abbey, Essex. I believe this is the only Strawberry that could be thus managed, except, perhaps, the red *Alpine*, as they force them in France.

GRAPES.—They, at least some of them, were splendid for this season. There was one dish of the *Muscot of Alexandria*, from Mr. George Wortley, of Norwood, the best I have yet seen in January—every berry was as full and shining as when it began to change colour last September. The usual way is to see them beginning to shrivel and turning into raisins at this season. Mr. Forbes, at the Duke of Bedford's, sent six bunches of very beautiful *Black Hambro's*, three of them being the crop of 1853 kept back, and three from the first crop of 1854, that is, the earliest and the latest crop, and were it not that green leaves were on the spurs accompanying the new Grapes, one could hardly make out which was which. The *Black St. Peter's* were never in better bloom, or fuller in the berry, in January, than were these *Hambro's*. Mr. Forbes must certainly have some secret method in keeping the *Black Hambro's* so late in such plump condition, and Mr. Wortley, gardener to Mrs. Maubert, of Norwood, has hold of this secret, else his *Muscots* could not come in an equally good full condition. In the ordinary process, all that gardeners can do for the preservation of their late Grapes is to stir the borders, and give a good drenching to the roots just as the berries begin to turn colour in the autumn; after that, the house inside, and the roots inside and outside, are kept as dry as can be.

There was a *Scotch Fir*, nine or ten feet high, all the way from Edinburgh, to show how well it did after being transplanted by the patent machine invented by Mr. MacGlashen, and there were several letters from

gardeners about Edinburgh, and in different parts of the country, many of whom I know personally, and from all these, and from what I had heard last summer, it appears that Mr. MacGlasheu's machines are in high repute in the north, and that thousands of trees and shrubs have been transplanted by them with the greatest success, but, somehow or other, we in England do not seem to value them half so much as they do; but I have no doubt, when we have seen more of them in use here, we shall like them better and use them.

D. BEATON.

LISYANTHUS RUSSELLIANUS.

This splendid *Gentianwort*, producing its large bell-like flowers in panicles at the end of the shoot, was introduced by Mr. Drummond, from Texas, nearly twenty years ago, and yet, with the exception of a few successful growers, it is even *now* very seldom seen in collections. Like many other plants rarely met with, it is by no means difficult to manage when the minutiae of its culture are, or can be, attended to; but whatever care be given, if these minutiae are neglected failure is sure to be the result. The two most successful growers I have met with are Mr. Cuthill, of Camberwell, and Mr. W. Thompson, of Wrotham Park. From the latter gentleman I received a plant and some seeds some ten years ago, and I grew it with very fair success for several seasons, and only got out of it from two causes. The first was, that from the quantity of things required, the plants did not receive the necessary attention when young; and the second was, that at that time having no plant-stove, I found that although the plants bloomed well in a greenhouse not over airy, that yet a closer and warmer atmosphere was necessary for the ripening of the seeds. In fact, my greenhouse-saved seeds would not vegetate.

When grown from seed the plant must be treated as a biennial. The seeds should be sown in pans, or pots, half-filled with drainage, then filled with equal portions of loam, leaf-mould, heath soil, and a portion of silver sand, sifting it so as to have three degrees of fineness—the roughest going over the drainage, the next in roughness over that, and the finest on the surface. Press that down level, and if not moderately moist, water, or dip the pot in a pail of water, until all is moistened, and allow to drain thoroughly for twenty-four hours in a warm place. Smooth the surface again by scattering previously, if necessary, a little of the finer compost over it, so that nothing will adhere to the pressing board; then sow the seeds; scatter very lightly a little silver sand over them, and press gently again. The month of March, or the beginning of April, is a good time for sowing, as the plants will just be in nice size for standing the following winter. The previous soaking, and then draining of the soil, will prevent the necessity of watering much before the plants are fairly up, and one source of disappointment will thus be avoided, as wet foliage they much dislike, especially when young. When the seeds are thus sown, cover the pot with a square of glass, or a bell-glass—the first is the best, as extra moisture will more easily escape—and cover that again with a piece of paper, so as to shade the seeds until they are fairly up. The best place for the seeds is any shaded place commanding an average temperature of from 70° to 75°, such as being plunged in a cucumber or melon-bed will give. When the seeds are up substitute a thin piece of paper for a thick one; but do not do away with the shade until the plants have got several healthy leaves, then the glass should be removed, and the thin paper, or other shade, continued a little longer, inuring them to more light by degrees. In watering, let the spout of the pot rest

against the side of the pan, so as to moisten the soil without wetting the plants. A better plan is to have a vessel of water, between 70° and 80° in temperature, and to hold the pot or pan in it within a quarter-of-an-inch of its rim, and thus, through the hole in the bottom, the water will rise, until you see the first symptoms of moistness on the surface, when the pot should be set where it can drain freely. The same plan would prevent myriads of delicate seedlings fogging or damping-off, as they now frequently do.

By Midsummer the plants will be large enough to pot singly in three-inch or four-inch pots, using soil similar to that mentioned above, with the addition of some small pieces of charcoal, to assist drainage; and these little plants should be again transferred to a close frame or pit; if they can be plunged in a mild bottom-heat, all the better. They will need shading from the sun for the first fortnight, and should be inured to more light and air by degrees, so that the young shoots be somewhat consolidated before autumn. If the leader seems to run away, it should have its point nipped out when four inches in length, that a sufficiency of shoots may be obtained, as at the end of good strong healthy shoots the panicles of bloom will be produced the following year. During the latter part of September, and the first part of October, the plants should have all the light possible, and as much air as would not unduly depress the temperature.

It will frequently be found, that a few side-shoots, two or three inches in length, may be removed from a young plant, or even from one showing and coming into bloom. These, taken off close to the stem, a few of the lower leaves removed and inserted in pure sand, above sandy loam, covered with a bell-glass, and placed in a sweet bottom-heat, will strike root, and when potted off will require just the same treatment as seedlings. In a packet of seed there will often be various shades of purple, and the spot at the base of the flowers will be brighter on some plants than upon others, and, in this case, cuttings are the readiest means for securing a superior variety. So far as my own practice extended, plants from cuttings bloomed equally freely with plants from seed, but were less luxuriant; the shoots producing their panicles when half the length of the shoots from seedlings.

The wintering of the young stubby plants is an important affair. After being well exposed in autumn, they should be moved by the middle of October into a warm greenhouse, a cool stove, or an intermediate house. The position should be dry rather than moist, and the plants should stand pretty near the glass, as near as would not subject them to sudden changes of temperature. The heat should hardly be long below 45°, and seldom for any length of time below 50°; they will enjoy 5° or 10° more with air. From this time in October, until the beginning of March, the plants must not flag, but they must not have more water than will keep them from doing so. If the bottom of the pots stood for an inch in damp sand or moss it would be an advantage. If water *must* be given above, avoid damping the stems or foliage. This will be easier guarded against if, in potting, the collar of the young plant is well elevated in the centre of the pot. During the whole of this period the syringe should never touch them. The drier the stem and foliage the better the plants will like it. This is just one reason why a person may grow a dozen or two more successfully than one. In the latter case, the spout of the pot and the syringe do the mischief before it is thought about. Green fly is apt to make its appearance, especially at this stage; and in fumigating with tobacco the fumes should be *weak* and *cool*, giving two or three weak doses instead of one strong one.

If by the first of March your plants are healthy,

stubby, and but little lengthened since last October, you have managed admirably. They must now get a start for blooming. Those who wish to gain a year, will, no doubt, find plants at Camberwell ready to begin with. Any forcing house or pit will do, where they can receive from 5° to 10° higher temperature.

If the pots could be plunged in a nice, sweet bottom heat, so that the roots would be 5° or 10° in advance of the top, the plant would thank you for it. The roots have been as stationary as the shoots during the winter; it is advisable to give them the first start. Whenever the roots are freely pushing out fresh fibres the plants must get a larger shift, and this may be done on the *successive*, or the *one shift*, system. An eight or ten-inch pot will grow a middling specimen. On the successive mode, giving two or three shifts by the month of May, there is less danger from over watering. On the one-shift mode, the soil should increase in roughness as you near the sides of the pot; a portion of charcoal should be incorporated, the whole well pressed, and water so judiciously given that the soil near the sides of the pot should never be wet, though moistish, until the roots begin to occupy it. With this attention as to watering, the one-shift system will involve, upon the whole, least trouble, and may often be used with great advantage with all plants grown only for that season. Whatever mode be adopted, though not absolutely necessary, yet, if the pots can be plunged so as to command a more equal, and a few degrees higher, temperature than the branches, it will be an advantage to the plant until the end of May. During this period, though air be given, yet a closish atmosphere should be secured to encourage growth. In June, the plants should have more air, and rather full exposure to light. After fresh growth in the head of the plant commenced the shoots should be tied out, and care taken to have them equal in strength. When growth is proceeding rapidly, not only will more water be necessary, but after the greater light and air that the plants receive in June, which will hasten the flowering process, they may have weak manure-waterings alternately with the clear. As the heat of summer advances the plants should have more air. Under such treatment, August and September will be their chief flowering months, opening their first buds towards the end of July. When in this condition, after being inured to the change gradually, they make fine ornaments for the parlour or the greenhouse; but as already stated, the seed cannot be depended on unless it is ripened in a higher temperature. It may also be noted, that unless the temperature be warm, and the position have plenty of light, the flowers will neither open so well nor have so good a colour.

I so forget the matter in Mr. Cuthill's monograph, that I do not know whether he describes a more royal, easier road to success than the above; the chief points of which, before they were reduced to practice by myself, were communicated to me by Mr. Thompson, many years ago. R. FISH.

THE CYCLAMEN.

A CORRESPONDENT has made inquiry how to improve our present race of Cyclamens, especially the more hardy kinds, such as *C. coum*, *C. Europeanum*, and *C. hederifolium*. As the subject requires some space—rather more than is given to replies in general to correspondents in their proper place—and as those plants are decidedly pretty gems when in bloom, and universally admired, I will answer the query for the benefit not only of the querist but for our readers generally.

The common Cyclamen grows wild on the hill sides of the south of Europe, and is so plentiful that the pigs feed upon the roots or bulbs—hence our English name,

Soubread. The *C. coum* is found at a considerable elevation on the Alps, where it is protected from the severe frost by the snow. When the warm days of spring partially melt the snow, this little plant may be seen with its beautiful deep pink blossom peeping through the white robe of the earth.

Thus hardy are the Cyclamens; and yet how many fail to grow and flower them well; and the reason, as I believe, is because the pure Alpine air, and the cool shelter of the snow, is not sufficiently attended to in their cultivation. On the contrary, as soon as they are out of bloom they are placed in some out-of-the-way place, perhaps under the drip of trees exposed to heavy rains, and saturated with wet while they last, and afterwards suffering from extreme drought, and the ravages of slugs and other vermin concealed amongst and under the pots. The wonder is that any are left alive under such unfavourable treatment.

To remedy this, I will try briefly to describe the proper culture, and shall divide the subject into—1st, Propagation; 2nd, Soil; 3rd, Potting; and 4th, Summer and Winter Treatment.

1st, *Propagation*—All the species must be propagated by seed. The bulbs are solid—that is, they have no coats like the Onion, or the Hyacinth, and they do not send forth any offsets like the solid bulb of the Crocus, or the Gladiolus. If a bulb of this latter is cut in two they will rot, and, consequently, perish, and so will that of the Cyclamen, and, therefore, they must be propagated by seed. The seed itself is very perishable and will not grow if kept too long; hence it must be sown as soon as it is ripe, which may be known by its changing colour and bursting the seed vessel. Sow it thinly in the compost I shall describe presently, in a wide, shallow pot, or pan, covering it about a quarter-of-an-inch; give a gentle watering, and place the pan in a cold frame. The greenhouse kinds may be placed on a shelf near the glass, but shaded from the mid-day sun; here they may remain till they come up, care being taken to keep the soil moderately moist by sprinkling it occasionally with water from a fine-rosed watering pot. By no means flood it, or pour the water on heavily, for if that is practised the seed will be washed bare and perish. Some of them may come up soon, but the greater part will remain under the soil till the spring. In this position they should remain until all grow, and then increase the quantity of water, but only just sufficient to thoroughly moisten it, withholding it then until the soil is moderately dry again. The beautiful single little seed-leaves will increase in size during the growing season, and each will form a small, tiny bulb. Towards the end of June the leaves will begin to turn brown and decay; then they must be allowed to go to rest, by giving no more water. Keep them in the pan, placing it in a cool place so contrived that no heavy rains can fall upon it. Towards the autumn they will begin to grow again, and as soon as that is observed stir the surface of the soil, clearing it of moss and lichens or weeds. Then put a thin coating of fresh soil on the surface, and water it to settle it close upon the small bulbs, which should not be covered too deep. I prefer keeping the young bulbs the second year in the same pan, because the first season they are so very small that there is danger of a considerable number being lost, if the attempt is made to transplant them, or take them up when a year old. Keep the soil again, during the second season, properly moistened, and when the leaves decay, allow them again to go to rest. When the season of growth arrives, then keep a watch upon them, and as soon as the least signs of growth are apparent provide a sufficient number of thumb-pots, the smallest size made, drain them well, and fill them with the compost, then carefully, with a flat, sharp stick, take up a bulb, and place it in the middle of the pot, leaving the upper part of it just

above the soil. If there are any living roots, preserve, if possible, every one of them. Proceed, bulb by bulb, till all are potted; then give a good watering, and place the pots upon a thick bed of coal-ashes, in a cool frame. Protect them during the winter from frost, giving air on all favourable occasions. Towards spring they will have made three or four leaves, and the pots will be found full of roots. A shift into a larger-sized pot will then be necessary, and will encourage the bulbs to increase in size very materially. I have even shifted them twice in the season with the best effect. By this close attention to re-potting, and a due supply of water, the bulbs will have increased to such a size that many of them will flower; and, in such species as are apt to sport, will reward the cultivator, very probably, with some improved varieties. T. APPLEBY.

(To be continued.)

WOODS AND FORESTS.

(Continued from page 301.)

Planting.—It has been said that "whoever fells a tree ought to plant a hundred," and, like most other old sayings, this is not only a wise one, even applied to the owner of woods for his own interest, but also is but honest to his posterity and the succeeding generations. If it is the duty of a private individual to replant his woods whenever he falls any quantity of timber, it surely is more especially the duty of the government of any country to replace any trees that it may be necessary, either for use as timber, or on account of age, to apply the axe to the root. And this remark applies with still greater force to the government of this country, inasmuch as timber for ship-building is so necessary for our grand national means of defence. Our greatest statesmen have always paid considerable attention to this point of political economy, and so greatly has its wisdom been pressed upon the attention of the legislature, that a commission has for many years been appointed to watch over and manage the forests belonging to the nation. Public attention has been lately drawn to this important duty of government by the press, and we may hope that the business of planting will now be carried on with spirit and in the best possible manner. Having made these few preface remarks, I shall now endeavour to describe the best mode of planting a track of land with timber trees. I have already alluded to the preparation of the ground by draining and digging, or otherwise making the ground ready for the trees. The first point to consider is, what kind of trees will grow best upon the space to be planted. If there is a fair depth of soil, then, by all means, plant it with that most valuable of all timber trees, the Oak, mixing them with some kind of Fir-trees, as nurses to shelter and draw them up for a few years. Very lately, I visited the seat of the Duke of Portland, at Welbeck Abbey, in Nottinghamshire, and had the pleasure of walking through the Oak plantations on that estate. This venerable nobleman is more than fourscore years old, and has, during his long life, been an energetic planter of this noble tree the Oak. I noted large labels on each plantation, on which is painted very legibly the date of each plantation, so that the rate of growth may be observed at once. They are planted (or sown I could not learn which) on ridges, or rather long beds. The younger ones stand thick on the beds, but are regularly thinned as they require it; but such as have been growing since 1834, the oldest date I came across, are now quite thin, with clean, straight poles, really beautiful specimens. In such a favourable soil and situation there is no need of nurses, neither have any been planted, but in less favoured spots they will be found

advantageous. The Oak will grow in almost any soil not actually wet or very much exposed.

In ground considerably elevated, or on hill sides, when the soil is thin, then let the Larch be the tree intended to make timber, mixing it with the Scotch Fir, the Birch, or the Beech, as nurses. In low, wet grounds, which cannot be drained, the Willow, the Poplar, and the Alder, should be planted, mixed with a few ashes, and the *Balm of Gilead*, *Spruce*, or *Silver Fir*, these to be planted on raised mounds. Indeed, the whole of these trees planted on such ground should be planted on ridges, the soil dug out to form the ridges being thrown upon them to elevate the ground above the water level, and increase the bed of soil for them to grow in. In positions near the sea-coast, such plants as will bear the breeze should be planted nearest to the water to shelter those further inland from the salt spray. The common Alder is one that bears the sea blast as well as any. If ever that beautiful tree, the *Arucaria imbricata* becomes common, it will be an excellent sea-side tree; for, as I remarked in my account of Badorgan, lately, there it is quite healthy and uninjured, though planted within a few yards of the sea-shore.

On the tops of our highest hills, the only way to get up a young plantation will be to plant it with the hardiest of trees, and that thickly, so that they may shelter each other. I noticed, lately, on some of the highest hills of Lancashire and Yorkshire, plantations of some extent, and there the hardy Scotch Fir, the Larch, and the Birch, have managed to stand the blasts, but the reason why they had not made much progress was, in my opinion, because the spaces planted are too small and isolated; yet I observed some in the centre of each plot that had made considerable more progress than the outside, showing, evidently, that larger plantations, even on such bleak positions, would, in time, shelter each other, and such barren spots would be then covered with thriving timber trees.

T. APPLEBY.

(To be continued.)

TEMPORARY HOTBEDS.

THE season having now arrived in which forcing of all kinds will be going on with great activity, the careful cultivator will often have his inventive powers put to the test, in order to ensure to everything that degree of warmth and shelter which is so essential to its well being; for, in many cases, the number of frames and other conveniences are not sufficient for the requirements of the season, that some "make shifts" have to be called into action, while, at the same time, every inch of glass is supposed to be hard at work as well. Now, though it would be idle to say that any substitute for a glass covering is as good as glass itself, yet many contrivances might be adopted which would either hasten on, or shelter, productions of a kind not too tender. For instance, *Potatoes* that were planted on a hotbed in December, might, by-and-by, have the frame taken away from them; the second crop, especially, might be made to dispense with such a luxury, and some frame-work of some kind or other erected which would admit of being covered up with some frost-proof material; while, at the same time, other beds might be made, and the *Potatoes* planted, which it would be unnecessary to humour with a glass covering at all if that material be wanted elsewhere.

Let us suppose that tree leaves, or dung, or both, exist in sufficient quantity to have a frame or two built with. Then, with this fermenting material, when in due order (according to directions so often given), let a sort of hotbed be made of any required length, but it

had better not be more than five or six feet wide; the height of three feet will probably do at this season. When this is done, procure some deals or rough slabs, and fix them edge-ways up all around the top of it, securing them at the corners to each other; and, if necessary, at one or two places in the middle, partition pins might be laid across, acting in the capacity of tie beams, by the sides being fastened to them. This being done, some contrivance must also be adopted with a view to support the covering that will be necessary to put upon this bed; one of the best being a waterproof oil cloth, or something that way, to support which a rail had better be carried along the centre, about two feet higher than the tops of these boards; this rail to be secured by posts driven into the bed, &c., and, if necessary, short pieces might be laid from the sides to it, in the manner of the rafters of a building, and it will easily be seen that over this, mats, or any other covering of that kind, might easily be thrown at any time.

From this it will easily be seen that a great amount of exposure must take place when light is wanted, consequently, very tender products must not be expected to thrive here; but, in fact, such delicate things as *Cucumbers*, and many other tender seedlings, ought to have some more suitable place, but as a succession of young *Potatoes* is no less necessary than *Cucumbers*, and a handful of *Radishes* a month or so before their natural season out-of-doors is often as much esteemed as a handful of flowers, it follows that any easy means of obtaining these must be worth the little labour they cost. Young *Carrots*, too, are esteemed a luxury at a season when the old ones are no longer palatable, and, by a similar contrivance to the above, their presence may be commanded some time before those in the open air come into use, and, what is equally important, in quite as good a condition as these are when of the same size.

If no preparations have been made by the amateur by the time these pages will reach him in the way of making such beds, no time must now be lost, and let the soil be at once put on, and the seed sown, or if for *Potatoes*, let them be planted: it is not much advantage to have them in the growing condition, which they often are prior to putting into a frame closely covered with glass, for in this latter case the warmth and shelter afforded is sufficient to maintain them in that growing state in which they have been before their final planting; whereas, to take up *Potatoes* which have made some progress from a warm floor, or bed, and remove them out-of-doors to where the only heat they have is a little at the bottom, subjects them to a check, which throws them farther back than those not started at all; however, a little sprouting at the eyes will do no harm, and in planting such make-shift beds it is advisable to use larger *Potatoes* for seed than for out-door planting generally.

When circumstances will admit of it, great advantage accrues from having the soil required for such beds in as dry and mellow a condition as possible; this may easily be effected when there are means for that purpose, as shed room, &c. It is also proper to observe that a very rich soil is not absolutely necessary for the purpose, although it must not be a poor or exhausted one, and for the *Carrots* a considerable quantity of sand, or other opening matter ought to be added, for this root is not benefited by much dung or other enriching substance of that kind. *Radishes* may be treated more liberally, perhaps, but the principal agents of success are in other causes, and one of the most important is the total exclusion of that cold harsh air so baneful to vegetation in the spring. If this can be accomplished without shutting out entirely light from the plant, then the object is gained; but as that cannot well be effected without glass, means must be taken to partially admit

the light, while a part of the covering remains on, or rather while some temporary covering is taking the place of the principal one. Oiled calico will do better than a dark body, or paper similarly prepared will answer equally well, only is not so durable, and requires a stretching frame, or something that way to support it on; but these things will easily suggest themselves to the operator; suffice it here to say, that anything that will admit the light, and check the coldness of the atmosphere, when the east wind is parching everything up, must be beneficial; only let it be borne in mind, that in as far as *Radishes* are concerned, a larger space of full exposure must be made, otherwise the plant will be nothing but top, or, what is equally bad, a long, useless neck. *Carrots* are more hardy, and as the seed is a long time in germinating, it is not necessary for the bed to have much light during the early part of this process; however, they must have light before they make their appearance, otherwise they will lack that robust sturdiness so necessary to their well-being afterwards.

It is almost needless pointing out the many purposes to which such beds may be adapted. A patch of *Cauliflower* and *Lettuce* seed, sown in such a place, furnishes plants long before the same kinds could be had in the ordinary way of out-door sowing; and it not unfrequently happens that the stock of autumn-sown of these things suffers much in a severe winter like the present; hence the necessity of replacing as many as possible. I may also observe, that *French Beans* do very well on a bed so treated, only they must be somewhat later, as their tropical origin ill fits them to endure the cold blasts so common in our springs; but of this I may probably speak hereafter. Nevertheless, many things might be sown here which are wanted in small quantities; and a little later, such a bed will be famous for raising annual flowers to plant out in the parterre and elsewhere; in fact, the uses of such a bed are manifold; and as the season is at hand wherein every inch of glass will be hard at work in the rearing and protecting things more tender or valuable, it behoves the careful cultivator to make the most of the means at his disposal; and if the common objects can be effected in a homely way, the mode in which that is done reflects more credit upon him than when a more expensive system has been at work; and as many residences in the vicinity of London can command hot stable-dung in any quantity, and as many country places abound in leaves in an almost equally unlimited extent, I advise each party to adopt a free use of each material; for whatever may be the merits of hot-water pipes and tanks, even when arranged in the most complete way, the day has not yet arrived when the old-fashioned dung-bed has to be driven out of use; although, in every fresh invention of the iron-and-water system, a threat is held out that the doom of all fermenting materials is sealed; but, somehow, the dung-bed yet rears its humble head annually in the back grounds as of yore; and though it would be unjust to affirm its produce in every respect came as early as that furnished by a well-regulated system of hot-water or other mode of applying fire-heat, yet it is much to be questioned whether any mode is more congenial to vegetation when that does show itself. And the results of horticultural shows in the summer months present as many good examples of Melon culture under the old-fashioned system as under the new, and the aspect of the foliage of things growing there fully corroborates that view—of course, taking the management into consideration likewise. But as far as that is concerned, the management of a plant, when luxuriating in the genial warmth conveyed by well-prepared fermenting materials, is an easy matter when the top or foliage of the plant is allowed to partake likewise of its exhilarating influence; but in the description of rough, half-exposed, beds, which this chapter has been devoted to, the kindly influence of

a nice genial heat has to be neutralized by frequent, full exposures to an atmosphere not the most agreeable to vegetation in a dormant state, let alone that of a highly excited kind. Nevertheless, this anomaly is partly got over by beginning in time, and a sort of sturdiness of top is attained when good management and attention are put in force.

J. ROBSON.

THE MANAGEMENT OF LONG-WOOLLED EWES AND LAMBS.

(Continued from page 323.)

UNDER the second head of the subject, I propose to consider the rearing of stock Lambs for grazing at a future period, as well as for keeping up the numerical strength of the flock. In breeding Lambs for sale as grazing stock, we must regard, in some measure, the requirements of the graziers as well as the profit of the breeder. It often happens, that in situations where the soil and climate is suitable, that a portion of the Ewes are purchased every year, and the produce in Lambs sold as stock; in this case, with any of the varieties of the Long-woolled Ewes, it is the best plan to use the Down Top for the purpose of rearing the first cross to be sold to the graziers, and for this object it will be found that no cross is so good as that obtained from the Hampshire Down breed. The mixture of this blood with that of the Long-woolled varieties effects a great improvement in the value of the stock; this cross not only making a great weight of mutton at a given age, but producing it of improved quality, as compared with the pure Long-woolled breeds,—the latter being, generally, somewhat deficient in lean meat, whereas the former will exhibit a well-combined proportion of both fat and flesh. It is from this circumstance that the cross-bred animals are more in request by the purveyor, and that they often realize in the live market a price very little below that of pure-bred Down sheep.

In stock flocks, where the object is to continue a particular breed of sheep, and to replenish the flock, after the annual sale of the old Ewes, by reserving the greater portion of Ewe Lambs, it is advisable to adhere as much as possible to distinctness of character and purity of blood. And in making a selection of Rams, and sometimes of a few Ewes also, I recommend that the origin of the flock should be carefully ascertained; and if it is traced to the same blood as that which it is intended to maintain, so much the better, if care and judgment has been displayed in the stock from which the choice is made; for I am of opinion, that breeding in-and-in (as it is called) is not objectionable, care being taken to procure, as a change, animals of the same blood, from different localities, where the difference of soil and situation will exercise a beneficial influence upon the constitution. I would further observe, that it is better to select Rams of the best quality from your own flock rather than take them from others of doubtful origin. It is well-known that parties have continued to breed from the same flock for upwards of fifty years without intermixture, and with great success; but this is evidently a matter of skill, and requires vigilant

attention, for it may be safely said, that in the case of many flocks now pampered by excessive feeding, for the purposes of exhibition, &c., if they were to be treated in the same manner, without a change by selection from other flocks, although managed with great judgment in other respects, great degeneracy, with weakness of constitution, would be the inevitable result.

In the department of Sheep farming called stock-breeding, it is necessary to consider the soil and locality; and generally, the thinnest soils, the most hilly, and the most exposed, are chosen for the purposes of keeping breeding Ewes; these conditions of soil and climate being unfavourable to the profitable production of fat stock. I do not propose to repeat the details of management necessary for a breeding flock, which I have previously gone into, and which will be found in the article on the treatment of Down Ewes, in No. 277 of THE COTTAGE GARDENER. In conclusion, I beg to express the conviction that the method of management there set forth, if fairly carried out, will be found quite sufficient, under ordinary circumstances, to ensure successful results.

JOSEPH BLUNDELL.

THE FATTING OF SHEEP.

OF all the branches of farming economy and the practical management of land, the fattening of Sheep is one of the most important; and when it is considered how many influences are in operation, in connection with this subject, it may well be said, that to make it profitable and successful at the present day, requires all the service that scientific attainment can render, and all the advantages which can be derived from practical knowledge and diligent application.

The fattening of Sheep in first-rate style, when conducted upon the modern and improved method, embraces a wide range of conditions, some of which are the kind of Sheep, and their age; the nature of the soil, its situation and aspect; the varieties of food, both natural and artificial; their cost and method of application; the influence of climate; the season of the year; and the rotation or system of cropping the land. All these, with others, which will pass under consideration during the treatment of this subject, must be received as necessary auxiliaries in the process, and all conducive, although varying in degree, to the success of the system. The first question to be asked is, Is our soil of the condition, staple, and quality, adopted to the fattening of Sheep? If not, it would be far better to keep a stock flock in preference to a grazing one, or else to appropriate the produce for a different purpose.

In the same degree that warmth is necessary to animals fattening under cover, in the like manner is shelter desirable to grazing Sheep in open-field-feeding; and as I propose to apportion a space in this paper to the consideration of the house-feeding of Sheep, I therefore intend my observations, in general, to apply to the method of fattening Sheep in the open field. I must, however, here observe, that although the advantage of moveable sheds for the Sheep to lie in during the winter

months, whilst feeding on Turnips, would be very great, yet we have no plan at present designed whereby we can gain by the shelter afforded, without being subject to the serious drawback of an accumulation, or unequal distribution of the manure. Any attempt at artificial protection, or shelter for Sheep, which induces them to collect together, has, moreover, the further disadvantage of propagating the foot lameness, which is of great moment at the present period, whilst there is so great a tendency in flocks to this disease. Could these difficulties be avoided, and shelter be afforded to the stock at a moderate cost, farmers would no doubt gladly avail themselves of the benefit.

The most important point is, no doubt, the selection of stock suitable to our soil, climate, and kind of food. In the northern and midland counties the Long-woolled breeds of Sheep greatly predominate; and hitherto it must be admitted that they have been considered best adapted to the profitable consumption of green crops, whether Grass or Turnips; but the plan of crossing with the Down is increasing rapidly, and this mixed breed is coming into favour with both grazier and consumer. This fact I hold to be the forerunner of another change, and that is the use of the Down breed of Sheep for fattening, in preference to the Long-woolled or cross breeds. The Hampshire Down breed of Sheep being not only well established as the best for profitable fattening, but reckoned the best adapted to the soil and climate of the southern, eastern, and south-western counties, the question then arises, what is the essential difference of soil and climate between these two districts, calling them the northern and southern, which should induce a preference? We have no more hardy breed amongst the Long-woolled tribes than the Hampshire; nor is the former to be preferred to the latter, for early maturity, or the profitable consumption of farm produce.

I am, therefore, inclined to think, that either breed must stand upon its own merit for fattening purposes, and in a great measure separate and apart from the influence of soil, particularly in the absence of any decided experiments proving the contrary. These observations apply more particularly to the winter-feeding upon roots, &c., for I am ready to admit that the Long-woolled Sheep would give the most profit in feeding the grass upon deep rich soils in the summer months, being of quieter habits.

JOSEPH BLUNDELL.

(To be continued.)

BANTAMS AS RECENTLY SHOWN.

THE farther we recede from the strictly profitable breeds of poultry, the more arbitrary becomes the standard by which those that remain must receive the verdict of the "faucier;" an expression especially suited to the diminutive race on which we now design to offer a few remarks arising from their public appearance during the past year. Excellence for the table, and a prolific character as layers, are rightly valued as counter-balancing certain deficiencies in form or feather, when we discuss the competing merits of economical poultry; and we have ever been of the number of those who think that in every question connected with

the poultry-yard, "*comparative cost and produce*" must be the main ground on which the claims of the various races must be founded. But with "bantams," form and feather are the sole points to receive attention; for few, if any, of their most ardent admirers would class them among the profitable fowls.

Now, taking them in the order in which they come before us in the catalogues of our various exhibitions, let us first ask whether the *Gold-laced* birds that have been shown during the past twelve months have been generally equal or superior to those of previous years? Our own observation would lead us, at once, to reply in the negative to this inquiry, and this opinion is based on a careful review of the majority of the principal exhibitions.

In very many instances the specimens have evidently been "*bred out*;" lacing has first become irregular, and at last spotty, till some birds, shown, too, with sanguine expectation in this class, appeared as bad representatives of the spangled variety. Few judges have been occupied, we imagine, for any great length of time before the pens of this section of the Bantam family; for wherever fair specimens have been present, their position has been at once assigned, and we have no hesitation in expressing our belief that, generally speaking, at least four out of every five pens were in no position to claim the honour of any token of commendation whatever. But though this may be admitted as the fact, it will be worth our while briefly to advert to the probable causes of this decline, which, though we cannot hope to throw any fresh light on the experience of many who have long studied this variety, may yet prove serviceable to the long list of those whose various circumstances enable them to gratify their taste for poultry only in the class before us.

Thus we may ask what has been the per centage of laced Bantam chicken hatched from the eggs of really good birds during the past year? Some of our friends, who have set hundreds, would answer, barely one per cent.; and though we will not insist on so low an average, we doubt whether any much higher rate could be proved, at least where the parent-birds, as before said, were really good specimens as judged by the recognized standard.

Comparing this with the healthy and numerous broods that other Bantams, Silver and Gold alone excepted, continue to produce, we must arrive at the conclusion, that in the selection of the parents of this variety we require certain features adverse to the vigorous and perfect propagation of their race; and at once, when we turn to the prize pen, the square henny tail, and the absence of both hackle and saddle feathers in the cock, points manifestly to the cause of their infertile character. We are, in fact, breeding from birds selected especially from their non-possession of the universal gallinaceous characteristics of the male sex. Add to this continuous breeding-in-and-in, from the difficulty of procuring fresh blood good enough, as it is thought, to mix with favourite and long-cherished strains, and we have more than sufficient reason fully to account for the present depreciation. But we might also allude to another influence, which will avail for our present purpose so far as it is considered that the laced Bantam "*originated*" with the late Sir John Sebright, being the result of his careful selection and continued experiments with other varieties of this family. If this supposition be correct, the result we now witness would be in strict analogical concurrence with all that takes place, under similar circumstances, in the rest of the animal kingdom. The peculiar form and character thus arrived at would inevitably wear itself out, in a longer or a shorter space, according to the greater or less difficulty of obtaining fresh birds that might help to reproduce the same points that first distinguished the variety. But we must not linger on this part of our subject, for a disquisition on the origin of the Sebright Bantam has no place in the present paper, where we merely propose to inquire into the fact of their assumed degeneracy.

An imperfect state of the organs of generation being in fowls commonly co-existent with the partial assumption of the plumage of the other sex, we have a ready clue to a cause which would account for the usual infertile character of the Sebright egg, and thence, going a step further, the degeneracy of their progeny in the comparatively few instances in which they do prove productive.

But putting this line of argument aside, another practice might be quoted as likely to tend to the loss of the cherished points of the laced Bantam's excellence. Late-hatched chickens of the year are very generally successful at exhibitions, a majority of prizes frequently falling to their share at six and seven months old. From prize birds it is often hastily concluded that prize chickens are most probably to be bred, and immature parents are consequently selected, producing chickens that either in form, or feather, or, perhaps, in both, must constantly evidence the want of judgment in such a choice. The mature bird, on the other hand, when at two or three years old the plumage has somewhat suffered in regularity, or colour, where, for instance, the abhorrent "*kite-wing*" has been developed, would have been far more likely to have thrown chickens that would have contributed to their owner's reputation.

The foregoing remarks apply equally to both the "gold" and "silver" varieties; both of these, indeed, as occasionally happens with Polands of the same colour, being hatched from eggs laid by the same parents. But to the deficiencies in the former birds, we have to add in the latter a tendency to coarseness and excess of size to which the others are not equally subject. This has been apparent for some years, and we see no reason to alter our opinion from those that have been lately exhibited. The clear silver tone, moreover, has too generally degenerated into a dull yellowish-white, or tending, on the other, to a light shade of bay.

Our readers need not be reminded that in penning these remarks many very beautiful specimens would plead exemption to the general opinion. We feel obliged to pronounce that Bantams have rather retrograded than otherwise during the past year; for there have certainly been instances where the occupants of pens would, perhaps, have borne comparison with the best of former days; but these have occurred but seldom, and when present have the more confirmed us in our low estimate of the beauty of their companions. We believe, also, that if there has been no improvement on a comparison of very recent times, the downward course of the laced Bantams would be still more apparent when contrasted with a period of fifteen or twenty years since; and that "*they are not what they were,*" would here be a more just application of that remark than in most cases in which we hear it used.

(To be continued.)

THE GENUS ANECTOCHILUS.

If there is a genus of plants that merits our attention, and excites a particular admiration more than another, it is certainly that of *Anectochilus*. Since the introduction of *Setaceus*, the first species from the island of Ceylon, no other plant surpasses the rich and splendid colour of its leaves. It is for peculiarity, that this and the allied genus, *Physurus*, have become so celebrated with cultivators. Unfortunately, however, the cultivation of these rare plants has been, and still is considered to be, very difficult by amateurs, so much so, indeed, that few of them have, hitherto, made the attempt, although they must regret the loss of such acquisition from their collections.

This last summer, however, I observed, at the exhibitions at the Chiswick gardens, that the whole collection of *Anectochilus* had been grown in a splendid state of culture, and also that they, by their extreme beauty, attracted the attention of visitors very much. Those plants, particularly favoured by nature, were never seen, perhaps, in so flourishing a state, but more commonly in a weak, wretched condition. Those exhibited, however, told plainly that there are means by which amateurs may enjoy these rare and magnificent beauties of nature. When I stood admiring these plants, I did not believe that their culture could be surpassed by any degree of skill. Some time afterwards, however, when on a visit to the Royal Botanic Gardens, at Kew, my attention was suddenly arrested by a rich collection of *Anectochilus*, of which all the species surpassed, by far, those which I had seen at the Chiswick exhibition.

The foreman of the propagating department, Mr. Hannemann, was the grower of these extraordinary plants, and he very kindly communicated to me the means by which he brought these plants to such admired perfection. Being

convinced that this knowledge would be of great use and pleasure to many amateurs, and wishing, at the same time, to contribute something to the embellishment of our hot-house, I subjoin a statement of the manner by which Mr. Hannemann's essays have been crowned with success. The compost he uses is one-third rough-chopped peat, one-third sand, and one-third chopped sphagnum (moss); to that compost is added a handful of horn, crushed to powder, and a few pieces of charcoal, to each pot. The plant is lightly potted in that compost, the pot is then plunged in another pot of a larger size, and the interval between the two pots is filled up with sphagnum, and on this outer pot a bell-glass is placed to secure the plant, which thus soon recovers from the effects of repotting. In this way the leaves, which constitute the only beauty of the plant, have room enough to spread themselves out on all sides. But the great secret of growing these plants to the utmost perfection seems to be in keeping the sphagnum, or moss, which covers both pots, in a free-growing state all the year round, and as our native moss from the woods must be used, it is forced to grow so much, that the surface of the pots must be as regularly gone over as the best-managed lawn or piece of grass, to keep down the luxuriant growth which the heat, damp, and confined air are always stimulating. At the nursery of Mr. Jackson and Son, in Kingston, where this treatment has also been adopted, and where it is found to answer beyond their sanguine expectation, the Orchid grower, Mr. Davidson, keeps pans of living sphagnum growing in the house, on purpose to have some of it near him when he wants to repair any failure on the pots under the glasses, and for potting these plants at any season. Neither Mr. Davidson nor his kind employers make a secret of the ways they find best to manage the rare plants, for which they are to be much praised. Another thing which they have discovered in the process of growing the *Anectochilus* family is very curious, and most useful to know, which is, that the bell-glasses never require to be wiped, as, no matter how long they are in use over these plants, if the sphagnum is kept alive there is no mouldiness or any green slime ever seen on the inside of the glass, as is seen to be the case with glasses which are used over cuttings or seeds in the ordinary way. The reason for this constant cleanliness inside the glass, they believe to be, that the sphagnum consumes all the damp vapours which must rise from the gradual decomposition of the different parts composing the mixture in which the plants and sphagnum are growing. When these damp vapours are loaded with the impurities from the compost, and when it is not so consumed, as it is not in the pots of cuttings, it is so troublesome to the propagator, by soiling the inside of his glasses, that he must have recourse to wiping them with a dry cloth every day, or very often, or else the mouldiness would soon spread, and involve his cuttings in ruin.

Mr. Davidson has been trying experiments, this winter, on purpose to prove how far the pure air, and cleanliness inside these glasses over the *Anectochili*, may assist cuttings of rare plants to make roots more speedily than under glasses, without sphagnum, on the old system; and as far as we can yet judge, there is cause to believe that the living sphagnum is the greatest help to the propagator that has yet been discovered. Besides this, they have already proved to demonstration that the whole race of these most beautiful-leaved plants which require bell-glasses to be kept over them, cannot be grown with any degree of success if the moss or sphagnum is dead about them, and, no doubt, the purifying influence of the living sphagnum, as is proved by the cuttings, is the chief reason why the *Anectochili* do so much better that way than on the older plan, with all the sphagnum dead and rotting about them, so as to make the air too impure for a lively growth in such confined space as that covered by a bell-glass. Without glasses it is not possible to imitate the natural conditions under which these plants are found; they form part of the vegetation which is capable of enduring the deep shades of trees and shrubs, and they are constantly surrounded by other low-growing plants of similar constitution, where neither sun or wind affect them much, so that they are always in a still, damp, hot, shaded atmosphere, which we can imitate only by the use of bell-glasses. We have also proved that liquid-manure from guano and other sources will excite them to

superior growth. Keeping them from flowering causes the same result; but this requires great judgment, as plants have been killed by the sudden decay of the stalks of the flowers; the safest way is not to take off but one flower-bud at one time, and that after the stalk is grown the full length, and so one bud after another, for a week, and then to cut off the flower-stem when it naturally begins to die; thus the leaves will receive all the nourishment which the flowers would have consumed.

Although the hottest temperature of our stoves would perfectly suit them, they content themselves, nevertheless, with a much lower temperature, like other hothouse plants, and then the watering must be comparatively diminished.

In Ceylon, and, likely, also in the other islands where they grow, the natives name them King of the Forest, and that with great propriety, although they grow so low on the ground among plants of like habit as the sphagnum of our own woods; and, certainly, the sphagnum agrees with them best, and with many cuttings as well, when it is surrounding them in a living, growing state. Therefore, it is very probable that the use of live moss or sphagnum will shortly be much extended in the propagating-house for many other purposes besides that of growing the living genus under consideration; or, failing that, I shall be happy if my account of what is now proved about the use of live moss, will be of use, or add to the pleasure of the English amateur, to whom, and to all with whom I have become acquainted in England, I owe my sincere gratitude for liberality and kindness.—H. G. HAACK.

[The author of the above original and interesting communication is a young student from Germany, who is over here for the sole purpose of learning our language, and our ways of doing business in the nursery trade, in order to qualify himself for superintending the British and American branches of that trade at home. How far he has made use of his means, may be judged of from this communication, when I say, from personal knowledge, that he could not speak a word of English this time last year.—D. BEATON.]

POULTRY SHOWS.

LIVERPOOL GRAND POULTRY SHOW.—This Show took place on the 18th and 19th of January, and though, from the vicinity of Knowsley, and the fact that many good breeders of poultry reside in that neighbourhood, we had been prepared for a good display, we confess the reality far exceeded our expectations, and we have no hesitation in saying (and we heard the Judges express the same opinion), that (*numbers considered*) it was the very best Show that has ever yet been held, there being scarcely a bad bird there. That the number of entries should not have exceeded 357, is a matter of surprise to us; but it was a first attempt so well carried out, however, that we venture to predict, that with a little judicious increase to the prize-lists, the next Liverpool Poultry Show will be second to none in the kingdom.

This Show was held in Mr. Lucas' Carriage Repository, which had undergone such alterations and improvements as left nothing to be desired in light, ventilation, accommodation, and effect, and testified to the "good taste," as well as energy, of the Working Committee.

The *Spanish*, which was a good class, consisted of 29 pens. It proved a walk-over for Captain Hornby, who with two beautiful pens (which we fancied were not his Birmingham birds, but *new faves* at a show) took 1st and 2nd prizes in the adult class, as well as 1st in the chickens, the 2nd prize going to a pen belonging to Mr. Hardy, of Warrington.

The *Coloured Dorkings* were pronounced by the Judges to be "highly meritorious," and well, indeed, they deserved the praise. The 1st and 2nd prizes for aged birds went to the Knowsley pens; and those for chickens to two beautiful lots belonging to Mrs. Townley Parker and Capt. Hornby. The commendations were numerous and well-merited.

Of *White Dorkings* we need only say, they were a moderate class, and shown in scarcely "moderate" condition.

Class 7, for adult *Cochin China* (cinnamon and buff), produced only eight entries, but they were good birds, and

in much better condition than has lately too often been the case. Mrs. Stowe taking the 1st prize, while the 2nd went to a pen belonging to Mr. Mitchell.

Class 8 must have given some little trouble to the Judges, as it contained 50 pens of much more than average merit. Mr. Harrison obtained the 1st prize, the 2nd being awarded to Capt. Hornby, for a pen scarcely inferior, in which, by-the-by, was one pullet quite the best in the Show.

Class 9, *Brown and Partridge-coloured*, was very moderate, but was redeemed by its follower Class 10, in which Mr. Archer, of Malvern, took 1st prize with an excellent and very heavy pen, the 2nd going to Mr. Job for a good lot.

In Class 11, *White Cochins-Chinas*, only one entry, and the prize was withheld on account of *green legs*; but Class 12 was one of much more than average merit, Mr. Rawson most deservedly taking 1st prize, and Mr. Job the 2nd.

The *Black Cochins-Chinas* were not in great force, and we observed, as is so general, coloured feathers in the cocks.

Of the *Adams* we cannot speak with "high commendation;" but must record our tribute of praise to the *Game*, which in all classes were much to be admired. More difficulty, however, might have attended the awards, had more attention been paid by their owners to proper arrangements, and had they remembered that in a *prize pen* the birds should match in *colours of legs* as well as other things. We saw good pens put "*hors de combat*," from the cock having yellow, and the hens white, legs, &c. For the various prizes in these, as well as the *Hamburgh* classes, which were of good average merit, we must refer our readers to the prize list.

Of all the *Poland* classes we cannot speak too highly. They possessed great merit, and were much admired. Mr. Beesley, Mr. Conyers, and Mr. Baker, received 1st prizes for their birds, and well-deserved them.

The *Bantams* had their usual crowd of fair admirers; Mr. Moss and Mr. Rawson showing some first-rate pens.

The *Geese* were well represented; the 1st and 2nd prizes being awarded to Mr. Townley Parker. There was not a pen in the class which was not fairly entitled to a prize, but the prize pens, especially the 1st, defied all competition. They were in beautiful order. We subjoin their weights as we heard them reported—gander, 23 lbs. 9 oz.; goose, 26 lbs. 14 oz.; goose, 21 lbs. 10 oz.—or 72 lbs. 1 oz. the pen.

The *Aylesbury Ducks* deserved great praise. The 1st prize in these went to a pair of Mr. Rawson's, which, if we mistake not, were successfully exhibited at Gloucester, but (we regret to add) in very different condition from their present state. The 2nd prize went to a good pen of Mr. Weston's.

The *Rouens* were shown in good condition, and were a good class. The prize-takers were Mr. Pearse and Mr. Worrall.

Class 12, for *Ducks of any variety*, brought twelve good pens to the post, the winners being Mr. Dixon, for East India Blacks, and Mr. Bird, with some beautiful Call Ducks.

The *Turkeys* bring us to the end of the list, and, like the *Geese*, possessed very great merit. The 1st prize was awarded to Mr. Conyers, whose Turkey cock was almost the finest we ever saw. Mr. Neilson took the 2nd prize with a pen scarcely inferior, as well as an extra 1st prize for "purity of blood," to a singularly good pen of wild American *Turkies*, which, from their condition and beauty of feather, were the objects of general admiration.

Every care and attention was paid to the feeding of the birds, and the courtesy and civility of every official connected with the Show ought not to be passed over. To Mr. Gilbert Moss is chiefly due the credit of originating and carrying-out so successfully the first Liverpool Poultry Show, and we sincerely congratulate him on the result of his exertions, arduous as we know they have been.

The Judges were Mr. Baily, of London, and Mr. Hewitt, of Birmingham, and their judgments gave general satisfaction.

A correspondent, and very excellent judge of Poultry, writes to us as follows:—"I consider the exhibition-room at the Liverpool Show one of the best adapted for the purpose I have yet seen, being well-lighted, and the ventilation of a very superior character indeed,—the latter being a necessary acquisition, when looked upon in connection with either the *health of the poultry*, or even the convenience of visitors.

and too generally *entirely* overlooked in the arrangements of a Poultry Show. The extreme cleanliness that pervaded every section of the Show reflects infinite credit on the Committee; and the result, in a pecuniary point of view, is a convincing test it was duly appreciated by the public, the attendance including almost every family of distinction in the county. I by no means expected to meet with so many first-rate specimens at Liverpool, and with pleasure do I acknowledge my belief that so general an amount of first-class birds have but rarely competed, while the influx of indifferent ones was unusually limited: a sufficient proof that the selection by exhibitors themselves improves steadily and satisfactorily. In *Game* fowls, however, this remark is inapplicable, many of decidedly superior pens being properly disqualified from the fact of yellow, black, and white legs being all exhibited together. The *Spanish*, coloured *Dorkings*, buff *Cochins*, *Game* (of all kinds), *Hamburghs* and *Polands* (of each variety), were excellent. In *Geese*, however, and *Turkeys*, it was evident the Judges had not a sinecure task, for the competition was, perhaps, the best yet witnessed; and such was the surpassingly beautiful pen of *Wild American Turkeys*, that belonged to John B. Neilson, of Doe Park, Woolton, near Liverpool, that an extra first prize was awarded them; and the *Aylesbury Ducks* were a very liberal and unusually good class. The first prize pen of *Rouen Ducks* were as true to feather as the most fastidious amateur could desire; but I long to see the weights approaching more nearly such as were, year after year, effected at Birmingham (varying from twenty-six to thirty-four pounds the set of four), for certainly great size (if combined with purity of breed) is quite a desideratum. There is no cause for doubting, a very few seasons will find Liverpool possessing an exhibition of poultry second only to Birmingham, and I hope that the Committee will meet with well-merited support."

Class 1.—*SPANISH*.—Cock and two Hens.—1. First prize, Capt. William Windham Hornby, Knowsley Cottage, Prescot. 2. Second prize, Mrs. Windham Hornby, Knowsley Cottage, Prescot. Class 2.—Cock and two Pullets.—26. First prize, Captain Windham Hornby, Knowsley Cottage, Prescot. Hatched Feb. 1st, 1853. 13. Second prize, Mr. John Willmott Hardy, Warrington. The cockerel hatched early in May; the pullets on May 20.

Class 3.—*DORKING* (Coloured).—Cock and two Hens.—33. First prize, Captain Windham Hornby, Knowsley Cottage, Prescot. 41. Second prize, Mrs. Windham Hornby, Knowsley Cottage, Prescot. (The whole class meritorious.) Class 4.—Cock and two Pullets.—47. First prize, Mrs. Katharine Townley Parker, Astley Hall, Chorley. Hatched 15th of April. 61. Second prize, Captain Windham Hornby, Knowsley Cottage, Prescot. Hatched 16th of April.

Class 5.—*DORKING* (White).—Cock and two Hens.—70. First prize, Mr. Joseph Jenners, Moseley, Birmingham. 72. Second prize, Mr. George Fell, Warrington. Class 6.—Cock and two Pullets.—75. First prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. Hatched May, 1853. 73. Second prize, Mr. R. Gibson, Hooley, near Crawley, Surrey. Seven months old.

Class 7.—*COCHIN-CHINA* (Cinnamon and Buff).—Cock and two Hens.—77. First prize, Mrs. Lydia C. Stowe, Bredon, near Tewkesbury, Worcestershire. 76. Second prize, Mr. William Mitchell, Keighley. Class 8.—Cock and two Pullets.—107. First prize, Mr. John Harrison, jun., Snelston Hall, near Ashbourn. Hatched middle of April. 117. Second prize, Captain Windham Hornby, Knowsley Cottage, Prescot. Hatched March 24th, 1853.

Class 9.—*COCHIN-CHINA* (Brown, and Partridge-feathered).—Cock and two Hens.—135. First prize, Mr. Joseph Hindson, Breck Road, Everton. 134. Second prize, Mr. Charles Leigh Clare, Hindley House, Liverpool. Class 10.—Cock and two Pullets.—140. First prize, Mr. Edward Archer, Great Malvern. Cock and hen hatched March 25th; other hen February 16th, 1853. 141. Second prize, Mr. Samuel Job, Holmefield House, Aighburth. Hatched 13th July, 1853.

Class 12.—*COCHIN-CHINA* (White).—Cock and two Pullets.—155. First prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. Hatched April, 1853. 153. Second prize, Mr. Samuel Job, Holmefield House, Aighburth. Hatched on the 9th of August, 1853.

Class 13.—*COCHIN-CHINA* (Black).—Cock and two Hens.—159. First prize, Mr. Howard B. Fox, New Ferry.

Class 15.—*MALAY*.—Cock and two Hens.—162. First prize, Mr. Thos. S. Trapp, Bedford. Class 16.—Cock and two Pullets.—166. First prize, Mr. Thos. S. Trapp, Bedford. Hatched in June.

Class 17.—*GAME FOWL* (White and Piles).—Cock and two Hens.—168. First prize, Mr. James Monsey, Ber-street, Norwich. 169. Second prize, Mr. Francis S. Bullock, Hawthorn House, Handsworth. Class 18.—Cock and two Pullets.—170. Second prize, Mr. James Monsey, Ber-street, Norwich. Six months old.

Class 19.—*GAME FOWL* (Black-breasted and other Reds).—Cock and two Hens.—191. First prize, Mr. Abraham Turner, Thornton Grange, Cheshire. 175. Second prize, Mr. William Cox, Brailsford Hall, near Derby. (Whole class commended.) Class 20.—Cock and two Pullets.—

189. First prize, Mr. James Monsey, Ber-street, Norwich. Age, six months. 188. Second prize, Mr. William Cox, Brailsford Hall, near Derby. Hatched April 10th.

Class 21.—*GAME FOWL* (Blacks and Brassy-winged, Greys and Blues).—Cock and two Hens.—202. First prize, Mr. Theed William Pearce, Bronham Road, Bedford. (Ducking Game.) Age: cock seven months; pullets eight months. 196. Second prize, Mr. James Dixon, Bradford. Class 22.—Cock and two Pullets.—206. First prize, Mr. Edwin L. Hullock, Handsworth, Staffordshire. Hatched June 30th. 207. Second prize, Mr. Samuel Taylor Smith, Park Lane, Madley. Age, nine months.

Class 23.—*GOLDEN-FENCILLE HAMBURGH*.—Cock and two Hens.—209. First prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. 208. Second prize, Mr. Henry Worrall, Knotty Ash House, Liverpool. Class 24.—Cock and two Pullets.—214. First prize, Mr. Josiah B. Chum, Coalbrookdale, Shropshire. Age, seven months.

Class 25.—*GOLDEN-SPANGLED HAMBURGH*.—Cock and two Hens.—221. First prize, Mr. George Fell, Warrington, Lancashire. Age, about one year and eight months. 219. Second prize, Mr. Thomas West, Eccleston, near St. Helens. Class 26.—Cock and two Pullets.—225. First prize, Mr. James Dixon, Bradford. 230. Second prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. Hatched April, 1853.

Class 27.—*SILVER-FENCILLE HAMBURGH*.—Cock and two Hens.—234. First prize, Mr. William Mitchell, Keighley. Class 28.—Cock and two Pullets.—239. First prize, Mr. William Mitchell, Keighley. 240. Second prize, Mr. James Dixon, Bradford.

Class 29.—*SILVER-SPANGLED HAMBURGH*.—Cock and two Hens.—247. First prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. 245. Second prize, Mr. William Mitchell, Keighley. Class 30.—Cock and two Pullets.—249. First prize, Mr. William Mitchell, Keighley. 252. Second prize, Mr. Edward Alison, jun., Park Hall, Chorley, Lancashire. Age, seven months.

Class 31.—*POLAND FOWL* (Black, with White Crests).—Cock and two Hens.—264. First prize, Mr. Thomas Beesley, Eccleston Lane Ends, near Prescot. Hatched in June, 1853. 260. Second prize, Mr. Joseph Conyers, 42, Boar Lane, Leeds. (Whole class meritorious.)

Class 32.—*POLAND FOWL* (Golden).—Cock and two Hens.—273. First prize, Mr. Joseph Conyers, 42, Boar Lane, Leeds. 267. Second prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. (Class highly meritorious.)

Class 33.—*POLAND FOWL* (Silver).—Cock and two Hens.—280. First prize, Mr. S. T. Baker, Manor House, King's Road, Chelsea. 282. Second prize, Mr. James F. Greenall, Grappendall Hall, Warrington. (Class highly meritorious.)

Class 34.—*BANTAMS* (Gold-laced).—Cock and two Hens.—290. First prize, Mr. Gilbert W. Moss, Liverpool. 293. Second prize, Mr. C. Rawson, The Hurst, Walton-on-Thames.

Class 35.—*BANTAMS* (Silver-laced).—295. First prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. 298. Second prize, Mr. C. Rawson, The Hurst, Walton-on-Thames.

Class 36.—*BANTAMS* (White).—Cock and two Hens.—300. First prize, Master R. M. Brocdelebank, Annsley, Aighburth.

Class 37.—*BANTAMS* (Black).—Cock and two Hens.—304. First prize, Mr. Gilbert W. Moss, Liverpool. Chickens of 1853. 302. Second prize, Mr. Joseph Conyers, 42, Boar Lane, Leeds.

Class 39.—*GEESE*.—Gander and two Geese.—307. First prize, Mrs. Katharine Townley Parker, Astley Hall, Chorley. 316. Second prize, Mrs. Katharine Townley Parker, Astley Hall, Chorley.

Class 40.—*DUCKS* (White Aylesbury).—Drake and two Ducks.—326. First prize, Mr. C. Rawson, The Hurst, Walton-on-Thames. 330. Second prize, Mr. John Weston, sea., Aylesbury, Buckinghamshire. (Class highly meritorious.)

Class 41.—*DUCKS* (Rouen).—Drake and two Ducks.—335. First prize, Mr. Theed W. Pearce, Bronham Road, Bedford. 337. Second prize, Mr. Henry Worrall, Knotty Ash House, Liverpool.

Class 42.—*DUCKS* (Any other variety).—Drake and two Ducks.—338. First prize, Mr. James Dixon, Bradford. (East India Black.) 339. Second prize, Mr. Lambert John Bird, Litherland Mowat, Litherland, near Liverpool. (Decoy or Call.)

Class 44.—*TURKEYS*.—Turkey Cock and two Hens.—353. First prize, Joseph Conyers, 42, Boar Lane, Leeds. (Cambridgeshire.) Weight of the three birds, 65lbs. 350. Second prize, Mr. John B. Neilson, Doe Park, Woolton, near Liverpool. (American.) Extra first prize for Purity of Breed.—357. Mr. John B. Neilson, Doe Park, Woolton, near Liverpool. (Wild American.)

DEVON AND CORNWALL POULTRY ASSOCIATION'S FIRST EXHIBITION.—This Society had their first show at St. George's Hall, Stonehouse, on the 18th and 19th of the present month, on which occasion 243 pens were entered for competition. This number would, probably, have been considerably exceeded, had it not been for the accidental collision, in the previous week, with the Torquay Exhibition, held in the present week, and also from what we must consider the unwise determination of the committee to confine the entries to residents in Cornwall and Devon. If the general improvement of our poultry-yards be the object of such Associations, it is manifest that such limitations must be prejudicial to success, for the wider the sphere of their operations, the greater probability is there of bringing together the best specimens of every breed; and another year we shall hope to number such restrictive

regulations among the rules that have been once for all abolished and done away with.

Class I included *Coloured Dorkings*, young and old; chickens here, as in the other breeds, competing with the adult birds. This class, as has been the case throughout the more western districts of England, was certainly below an average, for it could not be said to contain one really good pen. The first prize was awarded to Mr. W. C. Hodge, for No. 3, where there were two fair hens, but the cock had a sprigged comb, almost amounting to a "cup." Mr. E. Burton, of Truro, had the second prize, and Mr. W. W. Rowe's birds were commended. No *White Dorkings* were shown, though one pen had been entered.

Spanish, again, were below an average. To No. 10, belonging to Mr. B. Kingdon, an even pen of tolerable birds was assigned the first place, while No. 17 followed with specimens of a similar character, the property of Mr. B. Ford. Mr. W. W. Rowe had a commendation for No. 12, which contained the best bird (a pullet) of the entire class.

Of *Cinnamon and Buff Shanghaes* there were thirty-three pens, all possessing more or less of merit. Mr. W. J. Lawrence headed the list of awards with the same birds that lately won for him the like position at Penzance; Mr. Channing having the second prize for No. 34. No. 23 and 25, belonging to Mr. S. C. Parkhouse, were deservedly commended, as also was Mr. Channing, for No. 33. To pens 48, belonging to the Misses Coryton, of Pentlie Castle, and 44, to Mr. W. C. Pennington, of Penzance, high commendations were awarded.

Five pens of *Brown and Partridge Shanghaes* were exhibited, but the class was indifferent. Miss K. Buller took the first prize, though the cock was a decided *Cinnamon* bird. Mr. B. Ford came second, with No. 55, in which the cock was too stily a specimen.

Next were nine pens of *Black and White Shanghaes*, shown together, and forming but an unequal class. The first prize was here given to Mr. E. Burton, for No. 60, containing white birds, certainly the best in the class. The second prize to Mr. J. Turner, for No. 63, with black birds, of which the cock was indifferently booted, and had, moreover, a drooping comb. Mr. J. Turner was also commended for some very good white birds, in No. 56. The cock in 62 was not pure black, and still less so were the occupants of No. 64.

In *Malays*, Mr. Hunt walked over the course with a very good pen.

Red Game were inferior specimens, consequently the first prize was withheld, while Mr. M. Charlton took the second with a pair of good dark-legged hens, but an inferior yellow-legged cock. The best pen in the room belonged to Mr. Dent, but too late an entry had disqualified it from competition. *Grey Game* had six entries, of which Mr. J. W. Little's No. 75, had the first prize, and Mr. J. F. Mortimer the second; the latter pen was hardly inferior, except, perhaps, in the male bird.

In *Game*, any other variety, we found nine entries, of which several exhibited strange combinations of various breeds; thus, No. 79 had evidently been crossed with Golden Polands, and almost all the rest had a strain of Malay, or the coarse Indian Game blood. Mr. P. O. Treby's Piles took the first prize.

Silver-pencilled Hamburgs were mostly second rate. The first prize, here, fell to No. 89, belonging to the Misses Coryton, the second to Mr. W. W. Rowe.

In *Golden-pencilled Hamburgs* we found the winners in pen 103, the property of the Rev. H. V. L. Hammond; next to which came Mrs. B. Ford's, No. 102. Mr. Hine was commended for No. 101. These, on the whole, were a better class than the preceding.

There was no first prize in *Silver spangled Hamburgs*, but the second was given to Mr. Paul, No. 106.

In the *Golden-spangled* Mr. A. Paul had the first prize; Mr. H. Hine the second.

Golden Polands numbered six entries, and both prizes here fell to Mr. E. Burton. The *Silver* variety was badly represented, a second prize only being awarded to the pen of Mrs. T. Prideaux.

Plumignans, which here received the unusual honour of a separate class, were in three pens, of which Mr. F. P. Snyth was the owner of that which took the first prize, as,

also, of one commended. No. 34, the unnoticed, was an importation from Constantinople.

In *White Bantams* Mr. Channing took a second prize, and the same was awarded to Mr. J. G. Gully for his "black." The laced birds were represented by a single rejected pen, and the same with Guinea fowls.

Of *Turkeys* there were but two pens, for which a first prize was given to Mr. W. W. Rowe, for No. 146, and a second to Mr. Crawley, No. 145. Both of these were good.

Geese were of moderate quality, a second prize only being assigned to Mr. W. W. Rowe, who was also successful in the class for *Aylesbury Ducks*; Mr. R. E. Moore there following him in pen 150. The *Rouen Ducks* of Mr. E. Burton won the first prize, and some common Ducks of Mr. W. W. Rowe, the second, in the class provided for *coloured Ducks* generally.

The prize for *dead fowls* produced, among others, a pen of half-bred Barn door and Shanghae, that stood first in the awards; while, in the second place, there appeared the progeny of the above-named mongrels, with Spanish, both belonging to Mr. W. Bassett.

A prize having been offered for the best six eggs of any one breed, a somewhat indefinite proposition as to the points by which the award would be regulated, Mr. S. C. Parkhouse obtained both the first and second prizes with those of the Shanghae race.

In *Pigeons*, Mr. Channing won with Trumpeters and Almond Tumblers, and was also commended for his Carriers, the prize for which was given to Mr. W. T. Square, as, also, that for Pouters. Mr. E. Burton's Fantails and Runts were pronounced winners, and his Almond Tumblers were commended. The fact, that among *Extra Stock* there appeared the name of Mr. Channing, as taking prizes for his Turbits, Nuns, and Owls, showed clearly that the regular Pigeon class should not have been limited to a few arbitrarily selected varieties, but have included all that are now generally recognised. A prize was here allotted to the Frizzled fowls of Mr. T. Russell.

A Rabbit show was also permitted to add its attractions to the poultry pens, and here the name of Mr. G. M. Rowe appeared as the winner of the first prize, and that of Mr. J. P. Briggs for the second.

We understand that it is the intention of this Society to hold two annual Exhibitions, and that its second meeting will take place in the ensuing autumn, when chickens, principally, will appear for competition.

HARDY BORDER PLANTS.

(Continued from page 235.)

ACONTIUM JAPONICUM.

THE JAPAN WOLFSBANE.

THIS is one of the very best of the whole family of Monkshoods, being such a free bloomer, and its blossoms being very large, of a rich blue colour. Its roots are tuberous, supported by a large amount of fibres. It is readily increased by division, in the spring months, when putting up its first leaves. Its stems rise from three-and-a-half to five feet in height, much branched, and its panicked branches, short and numerous, forming a fine head of bloom. The leaves are much and deeply cut, the segments being narrow, often cut into threes. The whole plant is smooth, veiny, and of a dark green colour. It is a native of Japan, and was introduced to this country in 1790. It flourishes in common garden soil, and from its height and beauty forms a delightful back or centre row plant for either beds or borders; flowering from the end of June to the end of August.

T. W.

POST-MORTEM EXAMINATION OF A HEN COCK.

ALTHOUGH it is much more pleasant to proclaim that our opinions formerly published have been verified by knowledge subsequently acquired, yet, when truth only is our aim, there is a certain satisfaction in acknowledging that our

previous views were wrong; it is, as has been truly said, simply confessing that we are wiser to-day than we were yesterday. I am thus circumstanced with regard to the anatomy of the birds called *Hen-Cocks*, one of which I exhibited at the Surrey Summer Show, and described at page 369 of the last volume, stating that I regarded it as a male bird, with some arrest of development in the plumage. Recently I killed it for the purpose of examination, and found that it was simply a hen in which the ovary had never been developed, but had degenerated into a hard cartilaginous mass. This bird, as may be seen by referring to its description, was remarkably like a cock, in comb, wattles, general carriage, &c., and from its examination, therefore, I am induced to hazard an opinion that all so-called Hen-Cocks are simply hens in which the ovary has never been developed; this will account satisfactorily for the fact that those persons who (imagining them to be cocks) have endeavoured to breed from them have invariably failed to do so. In fact, I regard the only difference between what has been termed a Hen-Cock and a Crowing Hen (such as that whose *post-mortem* is described at page 128 of the present volume) to be, that in the Hen-Cock the ovary is never developed, or is diseased before it arrives at an active state; whilst in the Crowing Hen the ovary becomes diseased after having been in action, and, therefore, after the bird has laid.

The first condition, therefore, occurs in pullets, and as they grow they assume, more or less, the gait, comb, &c., of the cock—hence the name of Hen-Cock; the latter are old hens, who, having arrived at their full growth, necessarily retain their form and habits to a greater degree, and are, therefore, termed simply Crowing Hens.

Although both kinds may be kept as a matter of curiosity, it will be seen that they are quite unprofitable, in an economical point of view, as layers. I may mention, however, that Mr. Yarrell informed me that they are admirable nurses to broods of young chicken, but I have had no experience in their employment for this purpose.—W. B. TEGETMEIER, *Willesden, near London.*

SEA WEEDS.

(Continued from page 310.)

ORDER 10.—DELESSERIACEÆ.

We come next to the tenth order, *Delesseriaceæ*, which, though not very numerous, are extremely beautiful and attractive, both as regards colour and form.

1. DELESSERIA.

“Rose-red, flat, membranaceous, with a per-current midrib; fructification of two kinds on distinct individuals. Named in honour of M. Beig-Dellessert, a distinguished French naturalist.”—*Harvey.*

1. D. SANGUINEA (Blood-coloured).—Growing on rocks

in the sea, bearing numerous leaves from two to eight inches long, of a reddish-pink when living, but becoming a most lovely rose-colour, tinted sometimes with violet, when dried. The leaves, or fronds, are shaped like those of a Dock. The Rev. Dr. Landsborough mentions a beautiful variety of this plant which was once found floating at Sultivalts by Miss McLeish (a most zealous and diligent

weed-gatherer). It was a great bunch, of a dozen branches, some of the fronds being eight inches in length, and five-and-a-half in breadth. The peculiarity of this remarkable variety was, that it was lobed somewhat like *Delesseria sinuosa*, with a midrib in each lobe. Dr. L. also mentions a “magnificent frond of *D. sanguinea*, in the possession of Major Martin, of Ardrossan, thirteen inches long, and eight inches broad.” It is common, but so beautiful that it is universally admired. It is very fine on the Cumberland coast, and a blacksmith there sent me a number of fine specimens, and said he had cut about three hundred from the rocks. He is much interested in all branches of natural history, and it is a delightful recreation for him after the labours of the day are ended.

2. D. SINUOSA (Scalloped) is also common, but very pretty. It is a parasite on the larger algæ. In spring the young fronds are of a rosy-pink, but later in the season of a darker hue, and varying from a brownish-purple-red to crimson; when older still, the leaves are often tinted with green. It adheres well to paper when not too old.

3. D. ALATA (Winged).—Very abundant. The stem is much branched, and with a winged membrane, but no leaves. The colour is a deep red. This plant makes pretty specimens for the herbarium.

4. D. ANGUSTISSIMA (Narrowest).—Much like the last, but a narrower frond. Harvey says, that it appears to him an extreme variety of a variable plant.

5. D. HYPOGLOSSUM (Tongue-shaped).—The frond of this pretty *Delesseria* is much branched, so that it forms quite a little bush. The lance-shaped leaves have a midrib. It grows on rocks, and is parasitic on other algæ—is “from four to six inches in diameter.” In Ireland, the breadth of the frond is much greater than in British specimens. Colour varies from pink to red or crimson.

6. D. RUSCIFOLIA (Ruscus-leaved).—Not very common; the frond proliferous, and broader and shorter than the last. The colour is a fine red. On rocks, &c.

2. NITOPHYLLUM.

“Frond plane, delicately membranaceous, rose-coloured, reticulated, wholly without veins, or very slight vague ones towards the base. Fructification hemispherical capsules, imbedded in the substance of the frond, and ternate granules forming distinct scattered spots.”—*Greville.*

1. N. PUNCTATUM (Dotted). The frond is very thin, and divided into segments, the fructification scattered all over it. It grows on algæ, and is an annual and a summer weed. Harvey speaks of gigantic specimens found by Mr. D. Moore, at Cushendall Bay, north of Ireland, five feet long and three feet wide! A beautiful species.

2. N. HILLEE (Hill's).—“On rocks; rare; first found by Miss Hill, at Plymouth.” It is a handsome plant, of a sort of mulberry-colour, becoming orange-colour when put into fresh water. When recently gathered it has a very unpleasant smell.

3. N. BONNEMAISONI (Bodnemaïson's).—Rare. “Frond with a short cartilaginous stem, broadly fan-shaped, two to four inches long, and about as broad; more or less deeply cleft; substance very thin and delicate; closely adhering to paper.”—*Harvey.*

4. N. GMELINI (Gmelin's).—On rocks; rare; colour purplish-red.

5. N. LACERATUM (Lacerated).—The frond of this very variably shaped weed is much divided, and from two to ten inches in length; it is common, but makes pretty specimens. Very abundant indeed on the Cumberland coast, near Flimby, Maryport, Allonby, &c.

6. N. VERSICOLOR (Changing-coloured).—Rosy-red changing to orange-colour in fresh water. Miss Gifford says, that when the water first comes in contact with the frond it immediately loses its crispness, hissing and crackling like slackened lime, giving out at the same time a peculiar strong and pungent odour which makes the eyes smart. She has examined dozens of specimens in the hope of discovering the fructification, but without success. It has never been found in a growing state, but is thrown ashore by the tides, from June to August, in the south of England and Ireland.

3. PLOCAMIMUM.

“Frond filiform, compressed, between membranaceous and

cartilaginous; fine pink-red, much branched; branches distichous (alternately secund and pectinated); fructification of two kinds. The name is from a Greek word signifying braided hair."—*Greville*.

1. *PLOCAMUM COCCINEUM* (Scarlet)—This pretty weed is so common, and so well known, that it seems almost superfluous to describe it. It is a general favourite, with its beautiful and delicate crimson fronds. So common in some parts of Scotland, says Dr. Landsborough, that it is carted away for manure. It varies much in colour and in size, some specimens being almost coarse, others delicately pectinated, and very small. S. R.

(To be continued.)

ORCHARDS IN KENT.—No. 4.

CHERRIES.

ALTHOUGH the terms "Kentish Cherry" are familiar household words, yet the fruit does not occupy that prominent position, as an extensively cultivated one, which the name would imply, it being, in most districts of the county, of less importance than the Filbert, Black Currant, and Apple. However, it being of easy culture, it has in former years been more extensively planted than of late; and the number of new plantations making are very few indeed. Political measures, unnecessary here to mention, have opened out continental districts more suited to the growth of this fruit than our own precarious springs, consequently, London, and many other provincial towns, are supplied with Kentish Cherries that know nothing of the county, except, perhaps, in passing through it by rail or water. As my purpose is to describe the mode of culture adopted in Kent where this fruit is grown, I must leave the foreign produce to its own deserts, and, in the words of a worthy old grower, affirm, that if it was not for our late frosts in spring, we need not be afraid of foreign produce; but as we have no control over the late frosts very serious losses occur in consequence.

Contrary to most other cultivated fruits the Cherry does not seem to require a rich soil, or, rather, it is not necessary to supply it so frequently with those enriching substances which are so liberally applied to Filberts, Hops, &c., the Cherry being apt to "gum" off, or canker, when too grossly fed. In this respect it is a true type of the tribe of plants to which it belongs, for the Peach, in like manner, dislikes too high feeding, for it tends to produce in it a gony habit. Another thing the Cherry dislikes is much pruning or cutting, either at the top or root; the latter being equally injurious as the former; hence the plan of planting it in such a position as to secure its roots against injury in that way, which is done by planting it in a field afterwards laid down to permanent grass; but, in a general way, the ground at planting time is in a course of tillage, and often remains so for a year or two afterwards. It is proper to observe, that standard trees are universally planted, and these with a stem of not less than six or seven feet: the distance at which they are placed apart depends on various circumstances—they are to be found from twelve to thirty feet or more, but twenty-four is a very common distance. In selecting trees to plant, great care ought to be taken that they have not endured too much cutting at top. Maiden trees are preferable to those fine-headed ones which have only become so at the expense of their after-health, perhaps; for it not unfrequently happens that gum is found exuding from some of those wounds made by the knife. The roots ought also to be good and whole, and have been taken up with care, and the tree, after being duly planted, must be tied. It is a common practice in Kent, in tying up newly planted fruit-trees, to put in two stakes, one on each side of the tree, and in driving them in let their tops lean out from the tree a little, but not so much but that they will draw up to it when they are tied to it and to each other. The benefit of this is, that while they are pulling against each other they are each pulling against the tree, and, consequently, securing it against side winds, which would otherwise rock it backwards and forwards. I need hardly observe, that these stakes are placed on a line with what is expected to be the highest winds, which, in the district I write from, is south-west and west.

All being planted in what we may call a ploughed-field, we will leave the occupier to put in what description of crop he chooses, and it is usually corn that he sows; for, be it remembered, that small fruits are not often planted with the Cherry as they are with the Apple and Pear, consequently the ground must be put to some use during the early part of the tree's progress; but it very often happens that the one following the planting of the trees is the last crop from tillage, and if so, the ground is sown down to grass, in the usual way, while the corn is on the ground; but before that is done, I may as well relate a practice some have of throwing up a mound of earth around the stem of each tree, rounding it off so as to form a mole-hill-like mound of perhaps a cart-load of earth. Although this is not a universal plan it is a very general one, but its utility may be questioned; certainly, the additional weight it gives steadies the tree in a great measure, but if its roots were sufficiently deeply planted before this "earthing up," its utility is certainly questionable, except on light soils, where it secures a greater depth and increased moisture; however, many healthy Orchards exist without it. I must leave its adoption or not to those whose inclination directs them, and leaving that subject, will endeavour to describe what soils and situations Cherry Orchards are in general formed on.

The Cherry seems to delight in a much stiffer soil than most other cultivated fruits, for without wishing for the moisture so much relished by the Black Currant and Raspberry, the Cherry likes one more stiff than wet; hence many fine Orchards are found on such heavy lands as grow good Wheat and Beans, and such soils not unfrequently furnish a sward of grass likewise, the latter being the surface produce of an Orchard of this fruit. The ground, at the time of laying down, ought not to be poor and worn out, although, as I have before observed, much enriching matter in contact with the roots of the trees is to be deprecated. Now, apart from the stiff, heavy loam described above, Cherries, especially of the *Early May Duke* varieties, are often found on soils of a much drier description; in fact, on the dry hill-sides of the limestone formation. Some extensive Orchards of this kind are found on the banks of the Medway, in its course between Tunbridge and Maidstone, and on some of the lateral ridges with which the district abounds, and which I have, in a former article, described as peculiarly adapted to the Filbert and the Hop. This dry and stony, but by no means shallow, soil, supports a crop of Cherries very well where they escape the frosts they are so often visited with in the first week of May; and as the *May Duke* and its kindred early Cherries are always most in demand, the temptation to plant them extensively existed in greater force before "free trade" opened the market to foreign produce; since then, the later kinds, as the *Black Hearts*, *Bigarreau*, *Flemish*, and *Kentish*, have been more in demand.

I must not take leave of this article without saying, that after planting the tree must be protected against the injuries of cattle, &c., by something being securely fastened around them; when it is intended to graze the ground with sheep, which are certainly the best, some furze, or gorse, ought to be bound tightly around the tree and its two stakes afore-mentioned; or, what is better still, each tree might be surrounded by a timber fence; three stout stakes being set up in a triangular fashion, cross pieces might be nailed on sufficiently close to prevent sheep putting their heads through, and between the top bar and the second one a wide space is occupied by securing two pieces in a diagonal form, in fact, like the letter X, forming a sort of brace, which, taken in conjunction with the triangular form of the enclosure, gives it a more sturdy character than the slenderness of the materials used would lead us to expect. This species of protection is adopted very extensively with all sorts of standard trees, and, when well done, it looks neat and orderly. The three stakes used are generally about two feet apart at the bottom, and a little more at top. They cannot well be dispensed with until the trees attain a considerable size, and the bark assumes that rugged, uninviting aspect which age alone can give, and which renders them no longer assailable by sheep. This same remark holds good in regard to Apples and Pears, all of which are attacked by sheep, &c., when not protected.

Little pruning is given to the Cherry. Some unruly

growths are, perhaps, curbed a little at first, after that little more is required, as the branches have not that tendency to entangle amongst each other, and get thick, as the Apple and Pear; for some of the Cherries have an upright growth at first, and after having attained a certain height, they then, by their own weight, gradually spread and bend downwards.

The kinds most grown are two or three *Black Hearts*, having local names; the *Bigarreau*, of which there are three or four apparent varieties; and the *Kentish* and *Flemish*, which are a distinct section from the others, and of which there are more than one kind of each. The *Morello* is not much grown, yet I do not know the reason why; as a fruit it is, according to market prices, more than double the value of any other, the very earliest, perhaps, excepted. Some growers have also added to their stock the mere recent additions to the garden varieties, as the *Black Eagle*, *Tartarian*, *Elton*, &c., but they have not become generalised yet: and, as I have before observed, new Orchards are but sparingly formed, it is doubtful whether they have that trial they seemingly deserve.

In drawing this article to a close, I must not omit pointing out the advantages of having a considerable number of Cherry-trees together; for the preservation of the fruit from birds is a matter not so easily effected, and it is quite as difficult to keep them away from one tree as from a hundred; hence the advantage of having such a number together as will be worth the trouble of watching them, and there is no other way; and every gardener knows the difficulty of scaring these marauders away from such a tempting repast as ripe Cherries without the tolerable free use of gunpowder. Hence the advantage of having such a number of trees in one place as will afford keeping a vigilant watchman on the look-out continually; for these little depredators are up by early morn; and unless the produce be closely attended to, there will be few fit for use preserved from their rapaciousness; and in an Orchard of some acres of extent, netting and similar contrivances are out of the question.

H. B.

MORETON BAY IN AUSTRALIA.

THE letter of Edwin Smith, from South Australia, inserted at page 270, interested me much. I knew him and his father for many years; and, I might say, he left England from my house. He called on me among the very last he parted from; and I am very glad to hear he is likely to succeed. Here is another letter from a young gardener, a native of Perthshire, who went out from this place in 1852. The letter was read to me the other night by one of his friends here, and I asked permission to send a copy of it to the COTTAGE GARDENER; if only to infuse a little more of the spirit of emigration into the mass of clever young gardeners, who have little chance here to succeed to good situations. For myself, if I were on the right side of forty, I would even throw up a good situation and be off, for the sake of poor relations, if not to rough it out for my own advantage.—D. BEATON.

“Kangaroo Point, Brisbane, Moreton Bay, Aug. 7, 1853.

“You will, no doubt, be inquiring what sort of a place this is for gardeners. Certainly there are not many fine gardens; still, I could have got £2 2s per week as the above. But I have changed my occupation to that of a sawyer, as I can have £3 per week by working only five days a-week; and then not so hard as I used to do for 10s. per week. And were I to work only as day-labourer, I could get £1 10s. per week, and no slave-driving here; Jack's as good as his master. Provisions are as follows:—bread, 1s. 3d. per 4lb. loaf; beef, &c., 2d. per lb.; tea, 1s. 6d. per lb.; sugar, 3d. to 6d. per lb.; butter, 1s. 3d. per lb.; cheese, 6d. to 8d. per lb. Clothing, about the same as at home; as its all light clothing that is worn here, what would get a black coat, would dress you from top to toe. Glass and china are very high, and mostly all household furniture. The weather has been very dry these last two months, which is rare during the winter months; and when it does rain, it does in earnest; the winter crops are looking well, as the colder or winter months is the time to grow all hardy vegetables, such as

Potatoes, Cabbages, &c., and in the hotter or summer months, the Vine, and the Pine, and, in fact, this place will grow any and everything; only enter the dense scrub, there above your head is suspended the tender Orchid, while below your feet are entangled by Hoyas and Kennedias; in a word, this is the place to see the beauties of nature. But I must not overlook the natives as they lay about basking in the sun; its a hard case to induce them to work, as they will tell you, “white fellows work, black fellows eat.” I must give the ladies the praise for making them useful. And what amuses me most, they cannot bear a sight of them when they first come, but the one lets the other know how to speak to them, so that for a sheep's head, value 2d., you may have your cottage washed, water fetched, wood chopped, knives cleaned, shoes brushed, in fact, the Marys, as they call them, are the only servants. There is something strange in their nature, as they all leave the settlement just before sun down; and all Australia would not induce them to stop; they are a very timid kind of people after dark. Were you to visit them at their camp, the only request would be for some tobacco; even in asking that they would only open one of their eyes, and if the answer is No, shut it directly. I have only sent you these few lines to let you know that we have reached the Antipodes safely, and, in a word, those that wish to do well cannot fail in so doing here, as a man for from £20 to £30 can clear a piece of land that would support a large family. There is no such thing as charging for pasture, the animals are only branded with the name of the owner. Horses, cattle, and sheep, there stay in the hush for years without ever inquiring after. I am living about three miles from Mr. Caldwell; he has a place about one mile from the settlement, and is doing very well. I will not advise any one to leave home; but this I know, there is plenty of work and plenty of money. Even a policeman gets £7 per month, with wearing apparel found. And as beautiful a country as ere the sun shone on. By the same post I am writing for all my brothers to come out; and, perhaps, in a few weeks more, you will hear of your humble servant plodding his way to the diggings to try his luck there. Should any of you wish to come, the passage is pleasant, and plenty requiring your service. No poor people here to crave assistance; all are able to have a leg of mutton for dinner. JOSEPH GRAHAM.”

THE RIGHT AND WRONG WAY OF PLANTING.

IT is now just twenty years ago since I inclosed a strip of land, by the side of a road, on very clayey, wet, and indifferent subsoil. It was about two hundred yards long by about five wide; I posted, and railed it, and quick'd it. My first operation was to put a tile drain under it the whole length, about two and three feet deep; the fall was enough, and barely enough. I then trenched the whole of the ground about three feet deep; I had a fine old fellow about seventy years old (who was a “navy” in his younger days), living in a cottage of mine hard by, and I allowed him to do just as he liked with my little inclosure. It amused him, and kept him, which was my object. Every grinning blockhead who passed by had something to say about my buying the land dearly; but some had the good sense to admit that what I was doing was right, and would “stand for the job,” if it did not pay me. My object was to do the land well, or it would not have been worth doing at all, and better left uninclosed. I then planted a belt of trees upon it, consisting of Fir, Larch, Oak, Birch, &c. The plantation has grown to be the surprise of all who knew its origin: it is beautiful.

Now for the contrast. A neighbour, at the same time, inclosed a similar piece of land, and stuck in his trees any how; without draining, or trenching, or hardly digging, except a hole; and they present a miserable spectacle and contrast; and, I mean to say, that it would be better even now for him to pull them up, and to follow my plan; that is to say, if he means to have a good and thriving plantation at all. The question in these matters is this: does a man mean to accomplish that which he seems to be attempting? If he does, let him go the right way to work; if not, let him leave it alone. Mr. Appleby's most timely letters on planting forest trees have led me to make these remarks.

To look at the neglect of planting by the landed gentry of this country, and the neglect of their plantations and timber, generally, you would think them a set of mortgagees in possession, rather than the proud owners of English estates.
A WORCESTERSHIRE MAN.

TO CORRESPONDENTS.

* * We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of The Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

COCHIN-CHINA FOWLS (*A Norfolk Rector*).—We know of a few very good cockerels and pullets, of Sturgeon's breed, which will be parted with for ten shillings each; and, as in your case, they offer a good opportunity for improving the poultry in any neighbourhood.

CLOTTED CREAM.—*Fillingham* says, "I think I can supply your readers with a far more simple and practicable mode of making Devonshire, or clotted cream, than that mentioned in THE COTTAGE GARDENER. Keep the milk in block tin pans, which are far more cleanly and sweet than earthenware or wood. Place yesterday's milk over the top of a kitchen boiler, removing the iron opening; when the pan sounds dead by striking it with your finger take it off, and skim the cream the next morning. The heat will naturally force all the rich and creamy qualities of the milk to the surface."

SOWING CALENDRIA SPECIOSA (*An Ardent Amateur*).—The first week in March, or the first half of March, is the best time to sow the seed of *Calendria speciosa*; and the best soil for it is equal quantities of loam, peat, and sand; it likes good drainage, and does not require to be kept so moist as most plants. The seed pan should be in a hot frame till the seedlings are well up, after that the seedlings require more air and less heat than a frame gives. Sow the seeds thin, as the young seedlings are liable to damp if they stand crowded.

DAIED SPECIMENS (*Ibid*).—No one ever discovered a plan for drying specimens by which the colour of the flowers could be retained. After all, what is it but botanical haymaking, and we all know that hay does not show us the colour of the fresh material.

NUMBER OF BRITISH FERNS (*Ibid*).—No one can tell how many species of British Ferns there are, because it is so difficult to make out a species from a variety. We must rest contented with knowing how many kinds of Ferns belong to Great Britain, which are 197.

UMBRELLA ROSES (*Christopher*).—We take it you mean Standard Roses with the heads trained on an umbrella-like trellis, and we do not hesitate to say, that of all ways of training Roses that is the very worst. For constant bloomers, take Bourbon and Hybrid Perpetuals—Bouquet de Flora, Pierre de St. Cyr, Imperatrice Josephine, Barron Prevost, Mrs. Elliot, Madame Laffay, William Jesse, Pius the Ninth, Duchess of Sutherland, Comte de Montalivet, and Standard of Marengo.

FLOWER-GARDEN PLAN (*Yorkshire*).—We do not, and never did, pretend to select plants for a whole flower-garden. The plan is very good, however, except the four nearly triangular beds, embracing the central group; we shall change these to circles, and add four smaller circles in the centre, between the four half-moons, and four outside beds, then engrave it, when we shall say something about how the colours ought to stand, but we cannot select the plants.

EPIDENDRUM (*A. G., Liverpool*).—Your *Epidendrum* is one of the commonest weeds in all parts of the east coast of South America, from the Equator to the Mexican Gulf, and in the West India islands it is the smallest variety of *Cochlearia*, and is named, no doubt, in some botanical system, but gardeners take no account of any of these useless varieties. Your other plant cannot be determined from the specimen sent, which was crushed by the post-office.

CUTTINGS (*J. S. M.*).—We shall give an essay on making cuttings shortly that will meet your wishes.

NEWINGTON'S HAND DIGGLE (*A Subscriber from the beginning*).—This is an ingenious and useful implement for putting in small quantities of grain per acre. We have used it with good effect; but hand-dibbling is a tedious process, and it is difficult to get ordinary labourers to use it with care and skill; and as it is often a matter of importance to seize the most favourable opportunity when the weather above and the land beneath are in the most favourable condition, the slow action of the dibble is objectionable; and we prefer the drill, which ought to deposit a moderate quantity of seed at an uniform depth. The great fault in the use of the drill is in putting in too much seed so as to crowd the plants. We cannot speak practically as to the benefits of the hand-row cultivator, but the greater scarcity of labour which now prevails, in consequence of recent changes, points to the necessity of machinery calculated to dispense with a portion of manual labour.—W. C. S.

PREPARING FEATHERS (*A Parson's Sister*).—The chief requisite is to dry them thoroughly. This may be done by exposing them to the sun in a room, or by having them kiln-dried in bags. When perfectly dried, they should be put loosely into a bag and well beaten, to separate the dust from them. They are in the best state for pillows and beds after they have had the stump of each cut off, as they then do not force their way through the ticking.

WHITE BANTAMS (*Several Correspondents*).—We shall observe upon the decision in question next week.

GLASS (*Hortus*).—We have seen the ribbed glass used with perfect success for Cucumbers and other forcing.

RUSTICUS AND A CONSTANT SUBSCRIBER.—We cannot insert your notes but as advertisements.

MILBREW (*Mary*).—Nothing but being kept in a drier air will prevent the milder of which you complain. Your house, or room, must be damp.

BAKER-STREET POULTRY SHOW.—"I sent two pens of my Ptarmigans in the highest possible condition and cleanliness to the above show. I received them back on Tuesday morning, three whole days after the Show closed, and ten from the time they left home! They returned in so disgustingly filthy a state, that had they been kept the whole time in a pig-stye they could not have looked worse; both the cockerels had lost everyone of their beautiful long sickle tail feathers! Now, Mr. Editor, have I not a right to complain of this?—FREDERICK BERNAL."

DISEASED EAR IN RABBITS.—Mr. Allsop, the Rabbit fancier, says—"The cause is damp without good ventilation, and not being kept clean, and with good bedding. The cure is a little sweet oil put in the ear, and the lump then loosened with the thumb and finger until it will come out. If it should return, repeat the same, giving the Rabbit some sulphur in shorts, or barley-meal, moist."

ORCHARD PLANTING (*Troublesome*).—The best trees for your purpose will be either pyramids or dwarfs on the Paradise stock. If you understand how to manage pyramids, we would recommend them; if not, then choose dwarfs, to be grown in the form of a hollow basin. Plant them in rows running from north to south, with four trees in each row, and those at the extremities being each six feet from the walls, and the trees six feet distant from each other. The rows should be ten feet apart, and the distance between the extreme rows and the walls will be five feet—in this way you will have five rows. The Currants and Raspberries can be grown between the rows in the spaces of ten feet. In this way you will have a very pretty little orchard, and make the most of the room. The Morello Cherry you will, of course, plant against the walls.—H.

LIVERPOOL POULTRY SHOW (*Liverpudlian*).—It is quite impossible for us to sit in judgment upon birds we have not seen. Be assured, however, that with all competent judges, a well-matched pen of good form and in high condition will always be more considered than a pen deficient in those requisites, though superior in minor points.

LAURNUM TREE (*L. B. H.*).—As nothing thrives in the bed around, try some plants in pots, or tubs, plunged in the bed.

IRISH MOSS (*Ibid*).—Can any of our readers say "what quantity of Irish Moss ought to be boiled per day for a calf; and whether it is better mixed with either Linseed or Indian Meal?"

BUFF SHANGHAES (*Argus*).—To breed chickens of these with clear hackle you must select parents similarly gifted, and even then, for a generation or two, the hackle will not be immaculate. It is not, at present, possible to be sure of breeding such chickens. Your buff hen and golden hackled cinnamon cock will probably give some.

COOKING BEET-ROOT (*H.*).—There is as much reason in this as in roasting an egg. Enclose it in a paste of flour and water, and then either bake or boil it. There will be no earthy flavour in it then, and it is one of the most delicious and nutritious of vegetables.

SPANISH COCKEREL (*An Old Subscriber*).—The spasmodic affection of his legs has been caused, probably, by cold and damp. Let him be in a dry place, in a shed with ashes, or other dry, dusty materials for the floor, and with straw to sleep upon instead of a perch.

NAMES OF PLANTS (*Anne S.*).—Yours is *Epacris purpurascens*. (*A Young One*).—1. *Abies canadensis*. 2. *Cryptomeria japonica*. 3. *Pinus insignis*. 4. *Abies cephalonica*. 5. Not known. 6. *Pinus cembra*. 7. *Thuja Weareana*. 8. Some species of *Savin*. 9. *Escalonia tubra*. 13. *Helleborus niger*.

PROPERTIES OF ROUEN DUCKS (*A Subscriber*).—Hardihood of constitution; early maturity; and excellence of flavour. The Drake only should have the white collar. The colour, in both sexes, should approach as nearly as possible to that of the wild Mallard and Duck respectively. An average of good specimens of either sort would give the advantage in point of weight to the Rouen over the Aylesbury.—W.

GOLDEN-PENCILLED HAMBURGS (*A Poultry Woman*).—White down at the base of the tail of a Golden-Pencilled Hamburg cock is certainly objectionable. Your pullets of this breed, now nearly a year old, should have laid some eggs in the later autumn months, but the severe weather we have recently experienced may account for their present non-productiveness; and these fowls do not greatly distinguish themselves as winter layers. Good food and shelter is all we can advise, for whatever is calculated to force on the production of eggs must be ultimately detrimental to the bird. If you have a good run, the spring months will soon fill your egg-basket, but, if you cannot give your birds this indulgence, the sooner you cease to keep Hamburgs the better.—W.

TORQUAY SHOW.—"Allow me to correct an error in your report of the Torquay Poultry Show, with reference to the buff Shanghaes with which I took first prize there. They are stated to have been the same birds with which I gained the victory at Honiton. This is not altogether correct, one of the pullets having been different. At Honiton, the two shown were *Light of the Harem* and *Daisy*; at Torquay, *Light of the Harem* and *Wildflower*.—W. H. SNELL."

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kalendar; and Published by WILLIAM SONNERSVILLE ORR, of Church Hill, Walthamstow, in the County of Essex, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—February 2nd, 1854.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 45.6° and 31.3° respectively. The greatest heat, 65°, occurred on the 10th in 1831; and the lowest cold, 3°, on the 11th in 1845. During the period 117 days were fine, and on 72 rain fell.

BRITISH WILD FLOWERS.

(Continued from page 293.)

ARABIS TURRITA: Tower Wall Cress; Tower Turkey-pod; Great Tower Mustard.

Description.—It is a biennial. Root tapering, simple,

woody. Herb light green, more or less densely downy all over with fine, short, soft, starry hairs. Stem a foot or more in height, cylindrical, simple, erect, leafy. Leaves hairy on both sides, reversed-egg-shaped, broad, toothed, rather acute, but not pointed; the root ones tapering downward into foot-stalks; the rest heart-shaped at the base, clasping the stem; the uppermost gradually diminished into oblong bracts, each accompanying one of the short flower-stalks. Cluster flat-topped, nearly or quite simple. Petals pale sulphur-coloured, with a spreading border. Glands two at the inside of the shorter stamens, and two at the outside of the longer. Style very short, with a small, not dilated, stigma. Pods very long, flat channeled, thickened at the edges, curved downwards as they ripen, chiefly towards one side; their valves slightly undulated, not at all keeled; on short stalks. Seeds round, compressed.

Places where found.—On old walls and stony places; very rare. It has been found in Cambridge on the walls of Trinity and St. John's Colleges; in Oxford, on the walls of Magdalen College; and in Kinross-shire on the walls of Cleish Castle.

History.—This is the *Turritis major* of old botanists; and Ruellius, as observed by Gerarde, states of the whole genus—"the juice of the herb healeth ulcers of the mouth, and the poor peasant doth use the oil (of the seed) in banquets, and the rich in their lamps." It was thought by Bauhin, Ray, and others, to belong to the genus *Brassica*, and its glands are those of that genus, but its flat accumbent cotyledons, and simple row of seeds, added to the habit, settle it as a species of *Arabis*. It was found at Lewisham, before the year 1732, by Professor John Martyn. (Smith. *Withering*. Martyn. *Johnson's Gerarde*.)

THE present very high price of BREAD has brought to us such a multitude of complaints and queries—all suggestive of desirable information—that we will combine the answers and observations they have elicited in one prominent notice.

Every householder is competent to decide, from the evidence of his own eyes and his own palate, as to the quality of the bread offered to him; but whether the loaf be of the legal weight is not so obvious. We beg to warn our readers on this point, for the present high value of bread offers an additional temptation to bakers to be fraudulent—a temptation they have no great anxiety to resist. This is no uncharitable conclusion, for we know that of four four-pound loaves, each from a different baker, not one was deficient in weight less than four ounces. There used to be a very summary mode of

punishing such dishonest purveyors of bread, which, though contrary to the spirit of modern inflictions, yet might be wholesomely adopted without the attendant cruelty. A piece of wire was drawn through a loaf deficient of the assize weight, and the same wire was then passed through the baker's nose, and thus arrayed, seated on a hurdle with a label specifying his name and offence, he was dragged through the streets of the town. In Russia, without more to do, they used to nail the fraudulent baker by the ear to his own door-pest.

In mixing the flour for bread-making, it is of very great advantage to have either Bran or Rice boiled in the water employed. The increase of weight of bread obtained by so doing is very large, as will appear from two statements we shall append. It is true that such addition gives but little increase of nourishment, but

physiologists have thoroughly demonstrated that a certain quantity of food is as essential for health as a certain amount of nutrition.

A correspondent (A. B.) says:—

"I beg to enclose a receipt for cheap and wholesome bread for the poor. I have tried it with flour from which only the bran has been taken out, and it produced twenty-eight pounds of good bread; at the same time, and in the same oven, I baked fourteen pounds of flour in the usual way, which made eighteen pounds of bread. I then showed the different results, side by side, to our own labourers. Take a pound-and-a-half of whole rice, boil it gently over a slow fire in three quarts of water, for about five hours, stirring it occasionally, and afterwards beat it into a smooth paste. Mix this while warm into fourteen pounds of flour (*without any more water*), adding to it, at the same time, the usual quantity of yeast. Allow the dough to work the usual time, near the fire, after which divide it into loaves, and it will be found, when baked, to produce from twenty-eight to thirty pounds of excellent white bread."

A Prebendary of Durham, writing to his Diocesan some years ago, states as follows:—

"I caused four bushels of wheat (nine gallon measure) to be ground, and nothing but the coarse bran taken out: the produce was four bushels and a half of flour, and 22lb. of bran. About ten days ago, I boiled some of the bran, and kneaded a due proportion of the flour with the strained liquor, and the result of the experiment was so highly satisfactory that I resolved to repeat it with the most strict attention and the most scrupulous exactness. The details of this second experiment I am now about to communicate to your Lordship; and I thought proper to send you also some of the bread produced by it, that you might form a judgment of its excellence. Yesterday I took 5lb. of bran, boiled it, and with the liquor strained from it kneaded 56lb. of flour, adding the usual quantity of salt and yeast. When the dough was sufficiently risen, it was weighed, and divided into loaves; the weight, before being put into the oven, being 93 lb. 13 oz.; it was then baked two hours, and, some time after being drawn, the bread was weighed, and gave 83 lb. 8 oz. — loss in baking 10 lb. 5 oz. The same quantity of flour kneaded with common water loses about 15 lb. 11 oz. in the baking, and produces only 69 lb. 8 oz. of bread;—gain by my method 14 lb.; that is, a clear increase of one-fifth of the usual quantity of bread from a given quantity of flour. This increase, which at first appears astonishing, (since only 5 lb. of bran were boiled) seems to depend on a combination of three causes: first, the water in which the bran is boiled weighs half a pound more per gallon than plain water; secondly, owing to its glutinous consistence, it is less subject to evaporation by heat; thirdly, and principally, a greater quantity of it is necessary to make the dough; a bushel (or 56 lb.) of flour requires three gallons (*i. e.* 27 lb.) of plain water; but it imbibed three gallons and three quarts of bran water, weighing 35 lb. 10 oz. The bran, after being used in this way, is equally fit for many domestic purposes, and I suspect even more nutritious for pigs and poultry than if given to them raw. I had the curiosity to weigh it after the liquor was strained off, and found that it had gained 12 lb. and if water incorporates with it the same manner as it does with rice, why may not its nutritive power be increased in the same manner? The conjecture accords, at least, with Count Rumford's principle. But to return to my experiment: I have amused myself with the following calculation, which perhaps will make your Lordship smile. The increase of bread, by this method, being a fifth from a given quantity of flour, the consumption of flour would be saved by it every sixth day, or sixty days in a year. Supposing then that the practice were universally adopted, and taking the consumption of flour in this kingdom at 200,000 bushels per day, the annual saving would amount to 12 millions of bushels, which, at the present price, would cost about 10 millions sterling, and in ordinary times above four millions. Of the wholesomeness of the bread there can be no doubt; of its flavour you will judge by the specimen I have sent you; and I can add from experience, that it keeps very well. After my first

batch had been baked ten days, I put a loaf which remained of it into my oven for about 20 minutes, and, being suffered to grow cool again, it was cut, and had every appearance of new bread; nay, we even thought it better than it was at first."

It deserves to be better known, in support of the economy of using only stale bread, that during the great scarcity in 1800, an Act of Parliament was passed prohibiting bakers selling any bread "until the same shall have been baked twenty-four hours at the least." This act was founded upon evidence taken before a committee of the House of Commons, which demonstrated that one-half of the bread in London is consumed the day it is baked, and that if the bread were kept for twenty-four hours the saving would be from one-third to one-eighth of the whole consumption. That this is so was further substantiated by the Baker's Company stating that the consequence of the Act was to reduce the consumption of bread one-sixth.

With regard to the nutritive, yet cheaper, articles that may be advantageously mixed with Wheat flour for bread-making, we stated, in a former number, our own experience in adding boiled Potatoes, rubbed through a colander: and we have heard since that Turnips may be employed in the same mode. When the bread is twenty-four hours old, we are told that not the slightest taste of the Turnips is detectable. We have also received the following on this important enquiry:—

"The Editor of *The Cottage Lamp*, begs to draw the attention of 'S. E. J.' to the following receipts for cheap and wholesome bread, inserted in the September number of that Periodical, and taken from a very excellent work, 'The Family Economist.' They are as follows:—

"1st. Maize, one gallon; barley, one gallon; wheat flour, half-a-gallon.

"2nd. Maize, one gallon; wheat, one gallon. (This is an excellent bread.)

"3rd. One gallon each of oatmeal, barley, and wheat; or oatmeal and wheat, without barley.

"4th. Barley flour, one peck; wheat flour, half-a-gallon.

"5th. One gallon each of barley, rye, and wheat.

"6th. One gallon each of barley and rye; two gallons of wheat.

"7th. Buck wheat, one gallon; barley or rye, one gallon; wheat, two gallons. In using any of these mixtures, it is found best to ferment the wheat flour by itself, and then add it to the other materials, to make up, and rise in the usual way."

As the following suggestions from the Irish College of Physicians are somewhat more specific, and less general, than any others hitherto issued, we beg to recommend them to our readers.

The deplorable state of things on the banks of the Liffey is just a faithful exposition of the condition of all our great seaports; and until some change in the present system shall have been brought about it would almost seem that the more extensive the system of liquid sewerage, the more completely must our fine rivers be poisoned. Seeing that one-half of the cholera in England occurred in eight great seaports, the lowest parts suffering the most, it is impossible to over-estimate the significance of the warning which has

* See our remarks, Dec. 1st.

gone forth from the mouths of the Tync, the Thamos, and the Liffey: "precept upon precept; line upon line; here a little and there a little."

The danger from mismanagement of house sewers is not over-estimated by the committee. If used for getting rid of aught more powerful than slops and dishwashings, they should hardly communicate with the inside of houses, but the sink should be put down in a detached office. The daily flushing of house sewers (when a little chloride of lime may be employed) must be done at the ebb of the tide, or it will be productive of a doubtful benefit. There is no disputing the propriety of having privies and ash-pits at some distance from the house, carefully closed in, and regularly cleansed and emptied by the aid of covered scavenging carts, &c. The use of lime, chlorine, peat, charcoal, &c., we have already urged; also the direct sympathy between the skin and the bowels; and we concur in the committee's very rational remarks on diet. In a future number we hope to give their views of the treatment of the disease itself.

SANITARY MEASURES RECOMMENDED BY THE CHOLERA COMMITTEE OF THE COLLEGE OF PHYSICIANS IN IRELAND.

"The most important object, perhaps, that can be attempted, both in the public arrangement of a great city and in the domestic arrangement of houses, is *to secure an uninvited atmosphere, and, as far as possible, to preserve it from those foul exhalations with which it must become loaded wherever a great number of people are congregated in a comparatively small space.*

"To secure this object, more especially as a means of preventing the spread of epidemic diseases, the strictest attention to sewerage is imperatively necessary. The effect of deficient or imperfect sewerage on the spread of epidemics is so fully established that it may be regarded as indisputable.

"The facts observed in Great Britain and Ireland, during the prevalence of the epidemic cholera in 1849, if they do not place cholera and defective sewerage in the relation of cause and effect, at least prove an intimate connection between them. All manure heaps, filth of every description, stagnant pools of water, &c., should be immediately removed from the vicinity of dwellings.

"The main sewers should be frequently flushed with water, and all the communications between them and the atmosphere should be closed, except those requisite for drainage; the latter should be provided with water valves, or trapped so as to prevent the escape of recurrent effluvia.

"If the sewerage of the city of Dublin permitted, the committee think it would be advisable to have all the sewers flushed simultaneously.

"The refuse matter, street sweepings, &c., removed by the scavengers, should be so disposed in convenient depositories outside the city as not to become additional sources of danger; *moist filth should be covered over with dry materials*, so as to restrain evaporation, and the disengagement of offensive vapours, as far as possible; deodorizing substances, such as *dry turf mould, peat charcoal, or chloride of lime*, should be freely used to neutralise them.

"All occupants of houses, as well in the higher as in the lower walks of life, should be informed that it is not merely in the neglect of the main sewerage that a risk of promoting the spread of disease exists, there being scarcely a house of any class in which the sewerage and sculleries are not so mismanaged as to render them dangerous to the health of the inhabitants.

"All ash or filth pits should be, *as far as possible, kept apart from the dwelling-houses*, and carefully closed in or covered up by closely-fitted doors.

"All communication between the house sewers and the interior of the dwelling-house should be carefully closed, and those parts with which it is necessary to keep a com-

munication to get rid of liquid waste should be carefully fitted with water valves. The air of the dwelling-house being warmer than the air of sewers, and escaping by the doors, windows, chimneys, &c., tends to exhaust the sewers of their foul air, which, rising in the house to supply the place of the heated air which has escaped, keeps up a constant supply of foul air, which, passing from the sewers through the dwelling-house, is necessarily breathed by the occupants.

"The same observation applies to water-closets, privies, &c.

"The too prevalent practice of throwing filth into streets and lanes should be effectually prevented.

"The authorities should provide *covered carts for the removal, every morning*, of such matters as would otherwise be thrown into the street.

"The committee cannot too strongly reprobate the practice which they understand has recently grown up in the poorer districts, of converting *the cellars and kitchens, which have been condemned as residences*, into ash-pits and receptacles of all sorts of filth.

"The committee cannot avoid observing, that the sanitary condition of the metropolis of Ireland must, notwithstanding every temporary and partial effort at improvement, remain in an unsatisfactory state unless means be provided for effectually abating that greatest of all nuisances, an enormous open sewer, formed by a tidal river running through the middle of the city.

"The Liffey, under the present system, instead of being an ornament and an advantage, as it would be if it received only the natural drainage of the district contiguous to its banks, is converted into a receptacle of foul matters from the numerous sewers which contaminate its waters, and the deposits from which, being left exposed when the tide ebbs, taint the atmosphere to a great extent with the most offensive effluvia.

"Lodging-house keepers, and the landlords of tenements let out to the poor, should be subjected to the regulations against over-crowding; should procure an adequate supply of pipe-water; provide proper ash-pits and conveniences, and ensure proper ventilation,—by opening windows at stated times, by ventilators, perforated zinc plates, lowered openings, &c. Moderate fires in open grates assist ventilation, raising the temperature inside the house, and, at this season, aid in preserving the functions of the skin and bowels in a healthy state. Sudden alternations of temperature should be avoided; the internal heat of the house should not be so high that the effect of passing out into the open air would produce chill of the surface, and possibly breed complaint.

"White-washing *with fresh-burnt lime* is of great importance; and where the disease should unhappily break out, the committee advise chloride of lime, dissolved in water, for washing the floors of the house. Burials within the city should be discouraged. In very poor localities, where pipes are not laid down, a water-cart for the neighbourhood might dispense water at the houses of the most needy, for cleanliness and dressing wholesome food.

"The committee advise no sudden changes in habits of living when moderate and regular. A due allowance of animal food, fish, and vegetables, with the usual condiments, and wine, sound malt-liquor, or other accustomed stimulant, in moderate quantity, is unobjectionable. Excess should be avoided, particularly in the case of ardent spirits; and also of food likely to cause indigestion or bowel complaint, particularly unripe, decayed, or unsound fruit.

"*Between the functions of the bowels and skin a remarkable sympathy or consent exists*, so that attention should be paid to secure a healthy state of the latter by the occasional use of the warm bath, and clothing suitable to the season, in order to keep up a sufficient degree of activity in the superficial circulation. Flannel or woollen clothing next the person is preferable at this season, with strict attention to cleanliness, and frequent changes of clothing.

"In general, debilitating causes must be avoided, as excessive, long-continued fasting and fatigue, exposure to moist, stagnated air, or to air loaded with effluvia of organic matters."

J. J.

THE HARDY FRUIT QUESTION.

As it is my intention to run over this subject again at intervals, a desire appearing to exist to that effect—if we may judge by Mr. Fish's letter, and other applications—in doing so, instead of grappling with the question in the abstract, it will be well to analyse it a little, and let the several divisions representing main points of culture have separate attention. This will be found by far the most desirable course, as the young gardener, or amateur, who wishes to take up the subject in earnest, will have an opportunity, such as young folks have with geographical puzzles, of studying each in its own intrinsic character, and then of learning to "dove-tail" them all together in order to make a whole.

The question of *Stocks* is one which may be fairly investigated, but not thoroughly settled by any man. A vast difference of opinion exists, and there is some ground for it, and I much fear, that until every Pear we have, or receive, is fairly tried on both stocks, under proper circumstances, nothing sufficiently conclusive will be found. Nothing but here and there an isolated fact, all very well in itself, but contributing little towards such a system as would satisfy an ardent fruitist or a man of science.

Here, perhaps, I may be pardoned for stepping aside for a moment, and suggesting the propriety of having some public garden, in a central spot, devoted to experiments of this kind. The Horticultural Society of London has done much towards settling the nomenclature of fruit, but it would appear that such matters as I here suggest would carry them wide of their objects, and, indeed, prove too much for their machinery. Moreover, I should dispute their situation for such a trial. Pears and other tender fruits, proved to succeed there, might fail, under similar circumstances, when tried in our more northern parts. I would rather suggest a midland situation—say within a score miles of Birmingham, and rather on the north side than the south. Fruits well proved here would be eligible for any part of England, and most of our better Scotch and Irish climates; the locality selected would be a guarantee to those placed under inferior conditions, and would inspire the public with more confidence.

As it is, nothing is more common in the north than to hear people say, "Recommended by the Londoners; yes, but we have not the London climate." For when they come to hear talk of the fig-trees of Worthing, Lancing, and the neighbourhood, thriving like a Gooseberry bush, whilst they can scarcely grow them in the hot corner of a south wall, they naturally conclude that the southerners must possess immense advantages in point of climate.

In such a garden as that selected, the question of "stocks" should be pushed to its utmost; the influence of soils differing much in texture ascertained; the different modes of training well illustrated; and all kinds of protection principles carried out, in order to establish as much success and economy of application as possible. Now, such things would, I conceive, amply repay the fruit-growers of Britain, and I have little doubt, that with some ingenuity, such a garden might be made self-supporting after the first outlay. In such a garden (speaking now of Pears) I would make stations of about four feet square for Pears of every kind; one class of stations should be a strong loam; the second a light or sandy loam; and the third a fat, dark soil, of neither character exactly—a sort of alluvium—and this I would obtain by blending thoroughly such things as pond-mud, ditchings, furrowings, old leaf-soil, peat, or any debris of rotten vegetables, with a good deal of sand—all these materials well broken down, mellowed, and thoroughly mixed; the latter intended for Pears on the Quince, for in such a prepared station, I have grown

the *D'Arenberg* Pear of higher flavour on a Quince stock than those on the wall.

In thus pursuing the Pear question, some may want to know why all this fuss should be made as to trials. I will tell them, or, at least, give an opinion why. I have repeatedly urged, in the columns of *THE COTTAGE GARDENER*, that those who would give the Quince stock a fair and honest trial should start on what, for the present, I may term a common-sense foundation. The soil in which they are grown should, at least, be such as the Quince, in its own nature, and ungrafted, would delight in. Surely, no man of any standing in horticulture will deny the reasonableness of this position: to hunt for arguments to prove this were surely a work of supererogation. Well, then, there next arises the whys and wherefores of light and adhesive loams, and this, almost before I can explain, will be tolerably obvious to most of our readers. Soils, we know, vary exceedingly in different quarters; and although the chemist may so highly simplify matters in his laboratory as to appear to bring all the great facts connected with cultural matters into the compass of a nutshell, by the use of such highly concentrated terms as clay, chalk, sand, humus, &c., yet, only exchange his blowpipe, crucible, &c., for a spade and a wheelbarrow, and see what a quandary he will be in.

Looking apart from so grave a subject, we all know what strangely contradictory reports meet us on all sides about fruits, more especially Pears. We do, also, know that Pears crack during their swelling; that they sometimes ripen prematurely—sometimes are so tardy in this act as to become more like our Derby Spa Pears, such beauties as the tourist may see, but not taste, at the far-famed Matlock baths.

Now, it is not fair, surely, to charge all this on peculiarity of climate; this alone cannot account for it, inasmuch as I have repeatedly known the most contradictory results from gardens within a score miles of each other. Neither can it be peculiarity of site alone, nor comparative elevation; at least, so I have found it, although I by no means deny a modicum influence to all these things. I would, however, not beg the question here. I do not wish to give a preponderance to the question of soil; I merely wish to force it on public notice for awhile. Admitting, then, that a trial, as suggested, would be of service, it will be plain that two leading principles in the way of soils must be well represented, viz., adhesive loams, and light, or sandy loam; and grant with this, the reasonableness of allowing the Quince stock its own element, and I have the case I felt desirous to make out when I began this paper.

I do verily believe, then, that, although my good friend, Mr. Beaton, has almost forced a recantation on me in a this year's *COTTAGE GARDENER*, as to the Quince stock, yet I must beg respectfully to assure him, that I must still consider the question of stock an open question; inasmuch as we have, since the days of our childhood, frequently met with Pears of very superior character from the Quince stock; and, although, through force of circumstances, this same Quince may have been either overrated, or grievously misunderstood, yet this, in the minds of wide-thinking men, may by no means force a conclusion. Indeed, as to the question of stocks, "in the lump," who shall undertake to say that our grafting and budding systems, as performed by the ordinary routine, are worthy of the age we live in? The fact is, the knowledge of the most practical, or, if you will, theoretical of men, by no means satisfies himself; he knows well that this branch of horticultural lore is much in the rear of other portions of gardening, inasmuch as we still seem confined to the rules of our grand-sires. We are all on a devils track, where doubtful foot-prints alone may be seen to guide us; and to these,

I suppose, we must confine ourselves until we find a better road.

In conclusion. I see no chance of a happy delivery out of this labyrinth but by real experiment; but I fear that wars and war's rumours—those direful antagonists of peaceful progress—will, for awhile, cause many horticultural questions, only in their swaddling clothes, to hold the state of babyhood longer than usual. Let us, however, still watch the bantling with close attention, and still, though in an intermittent way, afford every help. Those who live at their ease, and fear not the fluctuation of events, have, at least, a chance of perusing such interesting matter.

R. ERRINGTON.

TREES AND SHRUBS.

In this list I shall not confine myself to those plants that have been recently introduced, because I intend it to be more generally useful, but I shall point out those more recently brought to notice. Many of the plants in my list have been already mentioned in this work, and treated of in full, and by turning back to the indices of former volumes their proper cultivation will be found in addition to what is here stated.

ILICUM FLORIDANUM, or Anised-Tree, is a low evergreen bush, growing slowly to six or eight feet, and requiring a damp sandy soil, and generally increased from layers. A native of swamps in Florida and Louisiana. Flowers of no account.

ILICUM RELIGIOSUM, recently introduced from Japan, is a very nice low plant, that will do well in a warm, sheltered place, but does not require a damp situation. Both these are evergreen, and require protection north of London in hard winters.

MAGNOLIA GRANDIFLORA.—Everybody knows this fine evergreen, but many do not know that there are several varieties of it, some of which do not flower with us worth a straw, and seedlings of it take a very long time before they come to a flowering age. The one called *Exmouth grandiflora* is the only kind really worth growing. It is known by the rustiness which covers the under side of the leaves. A *Magnolia grandiflora*, with the under side of the leaves green, is not worth having till it comes to a great age, and hardly then except in very warm situations. It requires dry sandy loam on a dry bottom, and is as hardy as the Portugal Laurel, but flowers best against a wall. It is best increased from layers.

MAGNOLIA GLAUCA AND *THOMSONIANA* is a fast-growing plant, and flowers early. The variety raised by Mr. Thomson, of the Mile-End Nursery, is the best, makes a beautiful lawn plant, and should not have a wall. The leaves are large, bluish-green, and fall off in the autumn.

MAGNOLIA TRIPETALA, called the Umbrella-Tree, on account of its very large leaves, and Elkwood, from the points of the shoots being like the horns of the elk. A very fast-growing, soft-wooded, deciduous plant, with very large white flowers; deep, rich soil, and a dry, sheltered situation, suit it best.

MAGNOLIA CONSPICUA.—This is one of the very best; it is one sheet of white blossom in April before the leaf comes, and when it comes of age it flowers as freely as *Tom Thumb*. No shrubbery should be without it.

MAGNOLIA MACROPHYLLA.—The long, large-leaved *Magnolia*, one of the scarcest, but one of the most noble-looking of the family, and comes nearest to the Umbrella-Tree. The leaves fall in the autumn. It requires a dry situation, and good, light soil, like all those large-leaved kinds.

MAGNOLIA ACCUMINATA.—This prefers a damp soil, but it will do almost in any soil, and for that reason it is generally used to graft others on, or scarce seedlings.

MAGNOLIA AURICULATA is also a large-leaved kind, which grows very fast, and is generally grafted on the last; they all have large, white flowers, and are amongst the finest-looking bushy or low trees of all we grow, whether in flower or not, and there are many seedling variations from each of them, which are highly valued by those who know them and can find room for them.

MAGNOLIA PURPUREA, with light purplish flowers, is a dwarf plant, often seen in American beds in front of large Rhododendrons. It is a very free-flowering, deciduous plant and very hardy. Any of the large-leaved kinds will graft on it as readily as on *acuminata*, and, like the Quince and Paradise stocks, it will dwarf on any of them, so as to make a miniature plantation of the most interesting kind imaginable; but for that way you must do the thing at home. There is no demand in the trade for these dwarfs.

EVERGREEN BERBERIES.—These, like the finer *Magnolias*, are not known half so much as they ought to be. There are nearly forty kinds of evergreen *Berberis*, and yet you can hardly meet with a person out of a great nursery who knows more than half-a-dozen of them. All that were known in 1850 have been described by Dr. Lindley, in the "Journal of the Horticultural Society," whence I abridge the following account of them.

CROWBERRY-LEAVED BERBERY (*Berberis empetrifolia*).—A well-known spiny and trailing low bush, for a bog-bed or a dry rockwork. It grows anywhere and anyhow. From the Land's End in South America.

STAR-SPINED BERBERY (*Berberis actinæantha*).—From Chili. A stiff bush, three feet high; grows anywhere, and spawns much from the roots. Flowers numerous, but very small—yellow, of course, like all of them.

BOX-LEAVED BERBERY (*Berberis buxifolia*).—This is only a better variety of one called *dulcis*, a native of Valdivia, off the west coast of South America, while the Box-leaved comes from Terra del Fuego. It is a variable plant, which is the cause of these aliases, *dulcis*, *rotundifolia*, *microphylla*, and *inermis*.

YELLOW BERBERY (*Berberis lutea*).—This was found by Mr. Lobb high up in the mountains (14,000 feet), near Veto, in Peru, whence he sent it to Mr. Veitch. It was found by Ruiz and Pavon, who first named it; and they said it was a large bush, eighteen feet high. It comes near to the beautiful *Berberis Darwinii*, and flowers in the same way. It grows in "coldish places," and stood out unharmed at the Exeter nursery of Mr. Veitch.

WALLICH'S BERBERY (*Berberis Wallichiana*, alias *macrophylla* and *atrovirens*).—"An evergreen of most beautiful aspect;" a native of Java, said to grow to ten feet, with leaves and flowers much like the common *aquifolium*. It was described in Dr. Wallich's great work on the Rare Plants of India, and was introduced by Mr. Veitch; but I have not heard if it is yet on sale, but it stood out with them at Exeter.

RAGGED BERBERY (*Berberis heterophylla*, alias *ilicifolia*).—The alias belongs to a pretty plant, and *heterophylla* is not worth growing except in botanic collections.

ILEX-LEAVED BERBERY (*Berberis ilicifolia*).—A very rare thing, said by Dr. Joseph Hooker to be the handsomest species in the genus, and grows to eight feet high in Terra del Fuego. This most splendid *Berberis* flowered at Kew, and then died, and must be got over again. A Captain going through the Straits, or rather coming home through the Straits of Magellan, might find it, if he were to lie to and send out in quest of it. The leaves are like an evergreen Oak, but of a darkish green above and whitish underneath.

DARWIN'S BERBERY (*Berberis Darwinii*).—Another gem of the first water, for which we are indebted to Mr. Lobb. It will grow five or six feet high, perhaps double

the size in our more favoured climate. It is a native of the islands of Chiloe and Valdivia, and on the main land as far as the Straits of Magellan, I believe.

SMALL-FLOWERED BERBERY (*Berberis parviflora*, alias *virgata*, but very different).—"It is a true evergreen, perfectly hardy, and rather handsome."

THE LONA BERBERY (*Berberis Loxensis*).—From the highlands near Lona, in Peru. Small flowers in erect clusters, and most beautiful foliage, deep shining green on both sides. Introduced by Mr. Veitch, through Mr. Lobb.

THE WAVY BERBERY (*Berberis undulata*).—From 12,000 feet high on the Peruvian Andes; small yellow flowers, in small, round clusters; fine wavy leaves, and growing to five or six feet high.

ORANGE-FLOWERED BERBERY (*Berberis Aurahuacensis*).—A most stupid name for a fine thing in Van Houtte's "Flore des Serres," from near the snowy mountains in New Grenada, at 9,000 feet elevation; and they are not quite sure yet if it is quite hardy. The flowers are in drooping racemes, and very deep yellow.

JAMIESON'S BERBERY (*Berberis Jamiesonii*).—Another very beautiful species in the way of *Wallichiana*, found by Hartweg, Purdie, and Dr. Jamieson, of Quito, to whom British gardens are much indebted, and after whom Mr. Veitch named it, he having sent them the seeds. Mr. Glendinning had seeds of it from Mr. Purdie, who collected for Kew. The flowers are in upright panicles. It "must certainly be a plant of great value in gardens."

THE WHITENED BERBERY (*Berberis dealbata*).—Raised in the garden of the Horticultural Society, in 1830. A stout plant, four to five feet high, with drooping flowers; a very well-known plant.

WHITE-BACKED BERBERY (*Berberis hypoleuca*).—From the north of India, by Dr. Royle, to the Horticultural Society; flowered in 1847. "A fine, handsome, ever-green bush," and "one of the stoutest of the genus;" also, "a remarkable fine species."

THE KUSHMUL BERBERY (*Berberis asiaticus*).—I had several standards of it at Shrubland Park; it soon makes a fellow to match a nice standard of the sea Buckthorn, *Hippophae rhamnoides*, and no garden should be without both of them, but as bushes, I would not give a fig for either of them. The Kushmul Berbery is the best hedge plant we have in England. A regiment of Cossack cavalry could not face it, or red deer either. It comes from seed, like Mustard and Cress, and grows as fast as any plant I know, also in any soil whatever. It is worse than the Black Thorn for poachers, in a game cover, and, altogether, a most valuable, or, rather, invaluable thing. There are many varieties of it from seed.

THE CHITRA BERBERY (*Berberis aristata*).—The native name is Chitra in Nepal. "The fine, close, bristle-pointed serratures of the leaves, the rich reddish-brown branches, and the long, loose, paniced racemes of (bright yellow) flowers, are quite peculiar to this plant, and separate it clearly from every other." The fruit is red, and hang on to Christmas. It goes under several wrong names, as *affinis*, *floribunda*, *Wallichiana*, &c.

THE UMBELLED BERBERY (*Berberis umbellata*, alias *angulosa* and *gracilis*).—A native of Kamaon, in the north of India. Grows here about four feet high; flowers in drooping racemes, and succeeded by oblong, purplish fruit. "The species is very pretty, in consequence of its graceful manner of growth."

THE DYER'S BERBERY (*Berberis tinctoria*), so named in consequence of furnishing, like other species, a fine yellow dye. A slender, low-growing shrub, of which we know but little yet in cultivation; it was only lately introduced by the East India Company.

THE OPHTHALMIC BERBERY (*Berberis lycium*).—"The real *Lycium indicum* of the Greek physicians," and,

"to this day its extract is used against ophthalmia with great success, as in the time of Dioscorides." A "bad evergreen, but a pretty summer bush." The flowers grow erect.

Section 3rd.—Leaves pinnate or trifoliate; that is, the leaves coming in threes together, or else in pairs, along after each other, as in the common Holly leaved Berbery.

THREE-LEAVED BERBERY (*Berberis trifoliata*).—From the North of Mexico, by Hartweg, to the Horticultural Society. A most beautiful, low-spreading, evergreen shrub, or you might call it ever-blue, for the leaves look like the blue Gum-trees of Australia in the shade; grows to three or four feet, and is quite hardy in Suffolk, and a very slow grower; a fine thing, but the beauty is in the leaves.

THIN-LEAVED BERBERY (*Berberis tenuifolia*).—Unfortunately too tender for our climate; it is with us a graceful tall plant for the conservatory; everybody admires the tall plant of it in the large conservatory of the Horticultural Society, at Chiswick. What a fine thing to send out to Australia, with the Japan and Chinese species.

EHRENBURG'S BERBERY (*Berberis Ehrenbergii*).—Not to be had in England, but it flowered on the Continent, and is described in *Linnaea* xx. 45, from the temperate parts of Mexico.

THE PALLID BERBERY (*Berberis pallida*).—From Mexico, and a very fine thing, but only a greenhouse plant in London, therefore out of my beat.

PRICKLY BERBERY (*Berberis fascicularis*).—Odd they should call this so, as it is not more prickly than any of the rest. A well-known low spreading bush, very like the common one, but more tender, and requires a wall, about London. Mr. Rivers got a cross between it and the common Holly-leaved, which is quite hardy, and intermediate between the two.

THE HOLLY-LEAVED BERBERY (*Berberis aquifolium*).—This is what I call the "Common Evergreen Berbery;" but I well recollect the day when I was asked five guineas for a little plant of it; then a guinea; then nine-pence a-piece; and last of all a couple of shillings the hundred seedlings. The most useful plant in cultivation; will grow in pure sand and stiff clay anywhere and anyhow. I once got a berry from it as large as a Black Hamburgh Grape, and, like the large Hamburgh I mentioned the other day, I wanted to do wonders with it, but I fear it will never set the Thames on fire. This is the species of which are the immense specimens I mentioned last spring, at Bank Grove, near Kingston; perhaps the finest in England.

THE CREEPING BERBERY (*Berberis repens*).—With all the looks of the last, this is only a low creeping rock plant, that never rises above a foot or so, but runs along by its creeping under-ground shoot in all directions.

CHAFF-STEMMED BERBERY (*Berberis glumacea*, alias *nerrosa*).—There never was a better-named plant; for it seems as if made on purpose to chaff the best of us until we get quite nervous for its slow growth, which is at the rate of about an inch in five years. It is a neat, stocky, little plant, and well worth growing for all that, and looks like a branch from the common just stuck in the ground.

NEPAUL ASI-LEAVED BERBERY (*Berberis Nepaulensis*, alias *pinnata*).—This long and much-talked-of Berbery was lately raised at Kew, and at the Garden of the Horticultural Society, but I believe first flowered with Mr. Pince, of Exeter. It was exhibited in bloom by the Horticultural Society in March, 1852, where I first saw it. A native of the north of India, and is believed to be hardy enough for England. A most noble plant, with strong upright clusters of rich yellow flowers, which are succeeded by a dark blue fruit of an oval figure.

ACANTHUS-LEAVED BERBERY (*Berberis Lechenaultii*, alias *acanthifolia*, both names by Dr. Wallich).—This is a more noble plant than the last, the leaves being eighteen inches long, with eleven or twelve pairs of leaflets. It is from the Nilgherries in the south of India, "found in almost every clump of jungle about Ootacamund." So that any one having friends at Madras, or in that presidency, might get any quantity of it. And the way to know it from the Nepaul plant is by its round berry, or fruit; the Nepaul one has oval berries. It is in England, but is very scarce.

FORTUNE'S CHINESE BERBERY (*Berberis Fortunei*).—Now a well-known species, with upright growth, four or five feet high, and too naked of leaves to make a very handsome plant; it is called the "Bamboo Berbery" by the Chinese.

MR. BEALE'S BERBERY (*Berberis Bealii*).—This is a splendid plant from the north of China, by Mr. Fortune, to the Messrs. Standish and Noble, of Bagshot. From dried specimens sent home by Fortune, Sir W. Hooker and Dr. Lindley mistook it for the *Ilex japonica*, of Thunberg; and *Bealii* is given as a second name to *Berberis japonica* in the "Journal of the Horticultural Society" for 1850, page 20. But Fortune stuck to his text, and maintained that his plant was very different from the *Ilex japonica*, and he was right; when his seedling plants appeared the proof was obvious. This and the next I saw at the Chiswick Show in June, 1852.

THREE-TINED BERBERY (*Berberis trifurca*).—A very strong leathery-leaved one from China, by Mr. Fortune, as above, the leaf ending in three strong spiry lobes, like the tines of a fork. It is mentioned in my account of the June Show at Chiswick, in 1852. It is largely cultivated in the province of Che Kiang for the dyers. It grows two degrees farther south than *Bealii*, and may be less hardy, but that we shall soon hear from Bagshot.

BERBERIS CONSANGUINEA.—This may be called the "Intermediate Berbery," that is, intermediate between *Bealii* and *trifurca*. It was found in the Green Tea district of Hwuychow, where *Bealii* was also found, and both must, therefore, be quite hardy here.

With the exception of Fortune's Berbery, all these from India, China, and Japan, seem to belong to one type, the *Ilex*, or Japan Holly, of Thunberg, who mistook an evergreen Berbery for a Holly. Those from Mexico and the north-west of America follow another type; those to the southward, to low swamps of Terra del Fuego, may be referable to a third type. If my eyes were bandaged, I could tell the China from the Indian ones by the feel of the leaf,—I mean the Nepaul and Acanthus-leaved *Berberis*,—the northern ones being so much more leathery and stouter. The Funeral Cypress of China is but a northern form of *Cupressus torulosa* from India, and the Deodar of India but another form of the Cedar of Lebanon, and yet the whole are so distinct, that a common labourer in the garden could tell the one from the other.

Now, this is a sample of the way I mean to give lists of all the trees and shrubs, old and young, that are, or can be, expected to bear our climate, if I live long enough. This is the most complete list of evergreen *Berberis* anywhere, and many of the eastern ones must be high-priced till they seed, when they will be as common as any of them. They all grow from cuttings, and, I believe, by grafting also; many of them make underground runners and suckers, by which they are readily multiplied; but seedlings alone can make them numerous and cheap. How would it do to graft the large-leaved kinds on tall stems of *Asiatica*? We have all kinds of standards, and why not standard evergreen *Berberis*? The seeds of all ought to be sown as soon as ripe; but they will not come up till the following spring. There is hardly a plant worth growing among the deciduous *Berberis* which may not be referred to

the original type, the common one of which there are more than twenty kinds, differing in some slight respects.

Another subject has just been handed over to my office—the Alphabet of Gardening—on which I shall enter next week. This is odd enough, for I began life as a Dominic. D. BEATON.

SOWING PELARGONIUM SEED.

"WHEN should Pelargonium seed be sown, and in what soil and circumstances; whether in a cool frame or a bed; I only possess a frame and southern window?" The above is merely one of several enquiries. The very best mode of action is one thing; the most proper, under the circumstances, is quite another affair. Professed florists hardly ever sow a Geranium seed at a venture. Even they, at times, raise seedlings far inferior to the plants from which they came; but by careful hybridizing, and anxious management, they work for improvements in habit and form. Many realize a peculiar pleasure in raising plants from seed, and attending to the little proteges in their infantile state, having a strong love for plants and flowers of all descriptions, and yet but little of the more refined taste and enthusiasm of the professed florist. And these are just the people to say—"Why should not our wishes be consulted? Florists know all about it already. It is not what suits the few, but what suits the million that is of any advantage to us. If we have a pleasure in raising a Geranium from seed, such as the mere tradesman never experiences, why should we not know how to do it in the simplest, as well as the best, way, and without being told to go back to this page in that far back volume?" I fully sympathise with feelings such as these. The first cuttings I struck were Scarlet Geraniums. The first seeds I sowed in a pot were a mixture of Pelargoniums. I had much less success with them in my first trials than with the cuttings, and yet, at last, in rather unfavourable circumstances, I succeeded pretty favourably. To meet the circumstances of various classes, I will give various modes of treatment.

1. When a hotbed can be commanded in autumn, and a greenhouse in winter, where a warm end can be appropriated, with an average temperature ranging from 45° to 50° during the cold, dark months, with a rise from sunshine. This may be considered the most favourable means for raising these plants and getting them early into bloom. In such a case, our experience would lead us to sow the seeds as soon as they were gathered and had lain a few days—say in the beginning of August. The seed-pans should have been previously prepared, draining them well, and filling them with a compost of equal parts of loam, heath-mould, and leaf-mould, with just sufficient silver sand to make it light and porous. Pots, six inches across, or wider, would answer just as well, if not better; but in their case, the drainage should occupy fully one-half, and the compost should consist of various degrees of fineness, the roughest over the drainage, and the finest on the surface. I mention the above compost as being good; but let no one fret himself because he cannot get it, for, as previously mentioned, the road-drift soil obtained from the side of the highway, well aired, and lightened, if necessary, with sand, and with, if obtainable, a little charcoal-dust, will be amply sufficient.

One great error among amateurs and young gardeners is using soil for sowing seeds and for potting in a dry, dusty state. Just fill a pot or a pan with such dry soil, with or without a plant, and see how many times you must use a water-pot before you can moisten it, and you will obtain a clue to the reason why many seeds never vegetate; and why, often, in the case of small seeds, the seedsman is blamed because no plants come in the pot,

after you have either scorch'd them or washed them overboard. I have often thought that this great error is partly based on the judicious custom we adopt of sowing seeds out-of-doors when the surface is nice and mellow and dry. Did we sow when the ground was clammy and wet, we should clog the seed, and prevent air having access to it, and therefore, when from necessity we do sow in such circumstances, we cover with some dry and light material. When we sow when the surface is dry, we know there is enough of moisture beneath to rise and swell the integuments of the seed, and that, even if a shower does come, the rain will pass through it, and thus leave air passages which would not be left if the ground was solid and wet before the rain came.

Now, though the seed of the *Pelargonium* is not small, and, therefore, may escape the evils to which small seeds are liable, still, in their case, as well as in all others where sowing in pots under glass is adopted, it is advisable to have the soil in a moistish state, such as can be effected by watering the seed-pots well a day before sowing, allowing them to drain thoroughly afterwards; or even setting the pots or pans in water, that they may be thoroughly saturated, and then allowing them to drain for twenty-four or forty-eight hours. This is based on the general principle, that the less young plants require from the water-pot before they are pricked out of the seedling pan, the less danger there is of damping, shanking, &c. A slight exception must be made in the case of seeds which are imperfectly ripened, or are getting rather old. In their case, when the bulk of the soil is thus moistened, some dry material should be placed on the surface, in which the seeds should be embedded, as too much moisture in their case would promote decomposition instead of germination. Even in the case of *Pelargonium* seed, when little drills are drawn about three-quarters-of-an-inch apart across the seed-pan, and the seeds deposited in them about one-twelfth-of-an-inch deep, a little dryish matter may be sprinkled over them, and gently pressed down with a board, or the bottom of a pot, as your previous preparation of the pots will ensure plenty of moisture for the roots to feed upon as soon as they protrude.

When thus sown, the pots should be plunged in a hotbed yielding a bottom-heat of 80°, and a top temperature of from 65° to 70°, and very little extra heat will yield that temperature at that season. In order to prevent the escape of moisture, and to hasten germination, the seed-pans should be shaded until the young plants appear, and if the seed is good you will not have to wait long. When fairly above ground, a little air should be given, but also a slight shade in bright sunshine. As soon as they have made a couple of roughish leaves they should be thinned out, pricking them into other seed-pans, or potting three or four round the sides of a three-inch pot. These should go again into the seed-bed, and receive the advantage of a sweet bottom-heat, be watered, aired, and shaded from the midday sun as before. In from three weeks to a month, all the strongest will require a three or four-inch pot separately; the weakest may continue in pans, or three or four in a pot. These, when thus fresh arranged, should be kept rather close to encourage growth at first, but as soon as roots are forming freely, more air must be gradually given during October, that the plants may be hardened off to stand, without shrinking, a lower temperature in winter. By the end of October, or soon after the middle, the plants should be transferred to an open, airy, warm part of the greenhouse, where they should stand not more than twelve or eighteen inches from the glass. Here they must receive what water they require, and be kept clear of dust and insects. In February and March, the single-potted plants may either have another shift into four or five-inch pots, or be top-dressed with rich

compost. It is waste of room to give these plants large pots until you see the bloom. You may expect to see flower-trusses from the earliest about Midsummer. The smaller plants shifted on in succession will be throwing up their flowers until the end of the autumn. If kept in the greenhouse all the summer, they will want watering very often, and if to save this you put them into larger pots you will retard the blooming. You will escape the double dilemma by placing the small pot inside a larger one, and placing moss between them. As soon as the flower-trusses appear, weak manure-waterings will give the flowers strength and size. If there are many plants, and you do not wish to fill the greenhouse with them, you would save labour by setting the small pots on a hard bottom out-of-doors, and plunging them in poor earth, sand, or ashes, after the middle of June, in a place exposed to the sun. If a plant shows bloom extra promising, lift the pot carefully, so as not to injure any roots that may have protruded, and place these roots, pot, and altogether, in a larger pot, water and shade for a day or two, and then give the plant a good position in the greenhouse. If you repotted such a plant in the usual way, you would give less justice to the bloom than if you had allowed the plant to remain in the bed. If you did not value the pot, and could crack it in several places, without injuring the roots, before placing it in a larger one, and filling the space between with compost, that would be the best mode of acting under the circumstances. When weak manure-waterings are frequently given, or a pinch of superphosphate of lime is placed on the surface of the soil, it is amazing what fine trusses of bloom may be obtained from a four-inch pot. Under the above mode, most of the seedlings may be bloomed the first season.

2. Where there is a hotbed, but no greenhouse. Follow exactly the same mode, only, in September, appropriate a light of the hotbed to the young plants, so that you may keep them rather close, and then give air to harden them off. You could not keep them in such a place easily without fire-heat during winter. It would be necessary, previous to November, therefore, to get them placed in the windows of sitting-rooms where there was firing in winter. To save trouble, a number of plants should be placed in one largish pot, or if three or four are placed in a four or five-inch pot, or a few singly, if they were packed in moss, in zinc trays, they would require but little attention in watering, and could be easily moved from place to place, as the weather and circumstances might dictate. The plants would not bloom quite so early, under such circumstances, unless great care was exercised to keep them clean, to save them from cold, and yet afford them every ray of sunshine.

3. Where there is a greenhouse, but no hotbed, only a few hand-lights and bell-glasses. In this case, suitable soil should be prepared in a box, to be set in the greenhouse, and covered with a bell-glass, or hand light, so as to warm the soil before sowing. Or, what we have found rather better, prepare a piece of ground on the south side of a fence, by taking away a little of the natural soil, placing a layer of drainage, and then several inches of the prepared compost, and watering it with warm water, and then placing a hand-light over it for several days, and not only allowing the interior to be heated with sun-heat during the day, but taking care to confine that heat by a covering at night, removing it only when the sun came the next day, or the day became warm. Here the seeds should be sown, as mentioned above, and a little air given only after the plants appeared. By keeping them in such places when pricked out, and taking great care in covering, shading, and air-giving, provided they be sown early, they will not be far behind those that had hotbed treatment,

while all risks from steam and over-heating are avoided. In such a case, the plants should be housed by the middle or the beginning of October. It will be seen that this mode is equally applicable to those possessing only a window and a couple of hand-lights.

The above modes have reference to sowing seeds as soon as ripe, by which extra earliness of blooming is secured, at the expense of extra and continued attention. I have sown the seeds exactly the same way in a hotbed in spring, and have had plants in bloom from three weeks and onward later than those sown the previous August and September. But, as a general rule, fewer plants bloom from spring-sowing during that season, but then, if kept in small pots during the winter, they will bloom early the following year, and the attention they will require in winter will be nothing in comparison of the care demanded from those young things raised in August or September. When the seed is saved over the winter, it is best kept in an airy place. A good plan is to hang it up in a sitting-room, in muslin bags; it is much injured by confined damp. I have no doubt that many, like the correspondent with whose inquiry we commenced this paper, will prefer, for this season, at least, spring-sowing. Keeping this in view, let us glance—

4. At the mode to be adopted where there is a frame, and a southern window. I should turn one light of this frame as quickly as possible into a hotbed, and when all was sweet and nice, I would place inside my pots of seed. If such a bed was designed for Cucumbers, a corner of it would be the very thing. If such a bed was designed for early Radishes, or Potatoes, it would be necessary to have a corner, over which you could place the top of a hand-light, or large bell-glass or two, so that in giving air to other things you could keep your plants as close and shaded as you pleased. Proceed, as closely as possible, according to the directions given in the first case. Your plants will be all the better for any extra heat they can derive from the hotbed until the first weeks in June, then, if you have a light or two of a cold frame at liberty, or from which the early crop has been removed, it would be the very place for them for a month or six weeks, as you could encourage them there, with a close, moist atmosphere, such as you could not command in your window. As they grow freely, give them more air by degrees. Encourage only one stem, and never think of stopping a shoot. When once you see the flower, and are satisfied therewith, you may make your plant as bushy as you like next year. By the middle of July, your plants may have abundance of air in your frame, be placed in your window sill, or even in a sheltered place out-of-doors. Many will bloom; and those which are too small to do so will be as easily kept over the winter in your window as any other small plant.

5. Where there are no conveniences except a window, or a cool greenhouse—and yet, for saving the trouble of wintering small plants, sowing in spring is resolved upon. In this case, unless means such as those referred to above are used for accumulating heat, the end of March will be early enough to sow. The best position for the seed would be no great distance from the kitchen fire-place; and after the plants were fairly up, and were set in the window, or greenhouse, with a large glass over them, tilted on one side as the temperature increased, they might be moved back to the chimney-piece at night, until the days and nights become warm. Even under such circumstances, where people were resolved to conquer difficulties, I have seen numbers bloom in the autumn. Even with very moderate attention, and delaying the sowing until the second week in April, nice shrubby plants were obtained, that stood the winter with but little trouble, and bloomed early the following season. Where there are a deficiency of conveniences and

a lack of labour power, I would decidedly recommend *spring-sowing*.

Two things are essential to early blooming; first, small pots; and secondly, giving no enriching manures, either in the shape of top-dressing or rich waterings until the flower-buds show themselves. R. FISHER.

THE CYCLAMEN.

(Continued from page 341.)

THE passion for new plants is so rife that good old ones, though ever so beautiful, have almost been driven out of cultivation; but there has been such great disappointment in many of the new plants sent out with high sounding names, and glowing descriptions of their beauty, that there is now a considerable reaction, and new plants are looked upon with a great amount of jealous fear that they either will not answer the character given to them by the introducer, or are difficult to grow and bloom satisfactorily. To prove this, I need only refer to two plants that caused quite a sensation at the time they were introduced—I mean the once famous *Plumbago Larpenæ*, and the no less be-praised *Fuchsia spectabilis*. No two plants ever introduced disappointed so much the plant-loving cultivator; and in a very few years, I have no doubt, they will sink into utter oblivion.

Not so with the subject of my present essay. They rarely disappoint the grower: though old in culture, they are as much esteemed as ever, and I trust they will be more so still as the knowledge of their culture becomes better understood. In my last paper, I described the method of propagating them, and I now proceed with the second part of the subject, namely,—

Soil.—It is well known to skilful propagators, that unless a plant has a proper soil to grow in it will not thrive satisfactorily. Heaths will not live in loam. Geraniums will not thrive and flower well in heath-mould; neither will New Holland plants generally grow well in either separately, but mixed together, with a due admixture of sand, this larger class of plants thrive and bloom to perfection. This having been found to be so by experience, the mixing of these soils has been practiced by all good cultivators, and the soils so mixed have very properly been termed a compost; and a mixed or compounded soil is suitable for the genus named *Cyclamen*.

The *compost* I use, and which I have found to answer remarkably well, consists of two parts loam of a rather light texture—such, for instance, as well-decomposed turf from an upland pasture would be after two years' exposure in the compost yard—and one part heath-mould, brought from a moor where the common Heath grows. This should also be laid up a year previous to using, to mellow it; and, lastly, one part of leaf-mould well decomposed. To these add about one-eighth silver sand. Mix these all well together, breaking the turfy parts with the hand, and picking out all the large roots of the Heath, or any large stones there may be amongst them; but by no means sift it, for if it is made fine by sifting it soon becomes so close and compact that water cannot penetrate it, or, if it does, it remains so long in it that the soil becomes sodden and sour, the fine roots die, and the plants no longer thrive, but become sickly and perish. This soil, or more properly speaking, the compost, should be mixed and prepared by being properly dried (that is, neither too wet nor too dry) in due time for the potting.

Potting.—This necessary operation should be done once every year, and the time for it is just before they begin to grow. The season for rest extends from the middle of June to the middle of September, or thereabouts; therefore, the repotting time will be about the first of October. In potting, proportion the size of the

pots to the size of the bulbs. Bulbs one inch across will require four-inch pots, whilst such as measure two inches diameter should have five-inch pots, and so on in the same ratio for less or larger bulbs. The utmost cleanliness should prevail in all the materials; the soil should be perfectly sweet, the pots either new or clean washed, and the drainage should also be clean. Old drainage will do if it is clean washed through several waters; but I always prefer fresh-broken crocks for these plants. Provide a little nice, sweet, clean moss, also, to place upon the drainage. In potting, proceed thus:—Lay a large piece of pot over the hole at the bottom of the pot, then lay round it a few lesser pieces, so as to cover the bottom of the pot; upon these place a layer of still smaller, enough to completely cover the last layer; then upon these last place a thin layer of moss. When this is carefully done the drainage will be effective. Then fill the pot with the compost nearly up to the rim, and then turn the ball of old soil out of the pot, and shake it out from amongst the roots. Clear away all that are dead, and spread the living ones out on the surface of the new soil; cover them over, and leave the bulbs just out of the soil; shake the soil down, and the operation is finished. Give no water for a time until fresh roots are produced. The after-treatment I must defer to another opportunity.

T. APPELBY.

(To be continued.)

WOODS AND FORESTS.

(Continued from page 341.)

PLANTING.—The season for this operation commences as soon as the leaves have fallen, and may be continued through all the winter months, weather permitting, up to the middle of March, always bearing this in mind, that the sooner it is finished, the more certainly there will be of the trees growing and doing well. If the trees have to be purchased from some nursery at a distance, the moment they arrive they should be laid in by the heels, as it is termed by planters. If the roots have become dry during the transit, they should, previous to being laid in, be thoroughly wetted, either by dipping their roots in water thickened with fine earth, or by pouring water upon them from a coarse-rosed water-pot. Whilst the roots are being wetted, let a long trench be opened deep enough to hold the roots. Then open the trees out, and lay them, not too thick, regularly in along the row, a man following quickly with a spade, to cover the roots, the great object being to get them covered up as soon as possible from the drying, shrivelling air.

By treating them thus the roots will be greatly preserved, and the chances of growing multiplied. I have, in the course of my experience, seen them very differently treated. To save trouble, the bundles of trees, when they came from the nursery, were placed close together, in outhouses, slightly covered with straw, and there they remained till time and weather permitted them to be planted. No wonder that more than one-half died by such injudicious treatment.

Many noblemen and gentlemen, finding this to be the case, have adopted the plan of devoting a plot of ground as a nursery, on their premises, purchasing small plants, and growing them for a year or two on the spot. This is a very advantageous method, inasmuch as the trees can then be taken up as many at once as can be planted in one day, and, consequently, there is more certainty of success, providing every due preparation of the ground is attended to previously to planting. But if the trees are had from a nursery, and carefully laid in, they will succeed very well, if the precaution is taken

not to take more up any morning than can be planted the same day.

The *size of the trees* to be planted is a subject requiring due consideration. In exposed situations, trees, three or four feet high, will be so blown and twisted about by the winds, that considerable numbers will perish, and such as do grow will be several years before they establish themselves firmly in the ground, however well the ground may have been prepared, and the trees firmly planted. It is a great mistake to suppose that there is anything gained by planting large trees, especially in unsheltered positions. One-and-a-half to two feet, at the farthest, are sizes that grow the best, because the wind has less power upon them. Besides this, the trees in the nursery-rows are generally planted thick, and then shelter each other, and, perhaps, have, in most cases, been growing for three or more years on the same plot of ground without being removed, hence the roots will be what are termed tap-rooted, with few side fibres; and these two points of growing thickly, and having only one or two straight tap-roots, operate greatly against a successful removal. Poor Richard says—"I never knew an oft-removed tree, nor yet an oft-removed family, that throve so well as one that settled be." He is quite true, if trees were not required to be moved; but where they must be transplanted, one or two removals, by increasing the number of fibrous roots, is not only not injurious, but positively beneficial. Hence, all good nurserymen transplant their stock of young trees at least every second year, planting them thinner each time. Trees so planted, and more especially Conifers and evergreen shrubs, are much more useful and valuable to the planter. This practice of removing, or transplanting, is now generally practised in most nurseries, and, consequently, a somewhat higher price is charged for them, which is but reasonable. For it is a considerable addition to the expense of a nursery these frequent removals.

In sheltered situations, the larger-sized trees so removed may be planted with every probability of success. Old neglected plantations that have been severely thinned will be a proper place to plant these larger trees. In such situations, small trees would very likely be smothered by rank grass, ferns, &c., besides, where game abounds, being cropped off by hares or rabbits; hence, to fill up woods that have been thinned, the trees should not be less than three feet high, providing they are well furnished with fibrous roots, and the ground stirred up well to plant them in. If hares or rabbits abound greatly, the trees should be protected from their bites. I have often seen numbers of nice young trees in such places, in severe winters like this, with the bark peeled off all around as high as these pests to the planter could reach. Last year I planted an orchard of five acres, and though the game hereabouts is by no means plentiful, yet they found out my Pear and Apple trees, and began to make havoc with the bark. I adopted a very simple protection, cheap, and easily applied, which completely stopped them from barking the trees, and that was, I set two men to daub the stems as high as the hares could reach with cow-dung, made thin with water, about the consistence of common paint. It was laid on with a home-made brush of common garden mat, and one application served through the winter. Not a single tree was touched afterwards. Now the expense of the cow-dung paint was trifling, and a man could daub over several hundred of these in a day. I can confidently recommend this simple, non-injurious application, a preventive of hares barking trees.

(To be continued.)

CULTURE OF TREES FOR LOCAL REQUIREMENTS.—THE LARCH.

It requires no great amount of poetic genius to pronounce healthy and well-regulated plantations of trees as one of the greatest ornaments of Nature, and the most careless observer of such things is seldom so far dead to all around him as not to feel pleasure, or its contrary, by the presence or absence of trees in the landscape before him. True, there are districts in which these noble productions of nature exist in too great a profusion to gratify the taste of the cultivated mind, which sees too much monotony to be pleased, unless it be accompanied also by something that is grand or sublime; however, there are few districts in this country to which this fault applies. The industry of the husbandman, through a long series of ages, has removed most of the traces of the primitive forests which encumbered this country at one time, and it is only here and there that a tract of land may be met with which there is reason to believe had never felt the plough or spade, nor any substitute for these useful implements of cultivation; such tracts are, however, to be met with occasionally, but they generally present a barren, uninviting aspect, and by their produce tell, in unmistakable terms, that much toil and trouble would be required to bring them into cultivation, and that when done, it would be very questionable whether such labour had been prudently expended. Other tracts certainly promise to do more, but then they are fenced in by certain trammels of the law in such a way as to debar all improvement. Of such class are some of the Royal Forests, which, however, may be more prudently looked after hereafter; but as this has been already adverted to elsewhere, I will advance no further, but beg to call attention to some matters more in detail as relates to the profitable culture of certain kinds of timber-trees, and the treatment necessary to their well-being.

There are few things connected with rural affairs of which more has been said than the pruning and thinning of forest-trees, and books and treatises innumerable have been sent abroad on the subject. Unfortunately, the most of these are couched in too general terms to serve in all instances, there being certain special cases wherein a treatment in direct variance with that generally given is not only excusable, but highly advisable, and as certain districts, or rather certain wants, give rise to these special cases, the one I am going to narrate may serve as an example to the rest, although they may, in each instance, differ much from it in the causes and effects which govern their respective conditions.

In travelling a little way from home with a friend from a distant county, who was an enthusiastic admirer of all Nature's productions, as well as a skillful and experienced manager of trees and woodlands, we came upon many objects which excited his anger, as well as others did his admiration, the latter feeling being, perhaps, confined to the effects which Nature produced, rather than through any well-directed skill in assisting her in such objects, and I have no doubt but (had he traversed this part of the county of Kent alone, without a chance of learning the wants and requirements of the district) he would have gone away, condemning us as the most barbarous managers of trees and woodlands that had any existence in a civilized country. Hedge-row trees, lopped from the ground almost up to their very tips; others, beheaded, and that operation having been several times repeated had given their trunks a singularly hideous appearance when seen for the first time by a stranger, and more especially so if it was in the dusk; but what drew from him most condemnation, was a plantation of young Larch Firs, which, to him, appeared like a large nursery abandoned to its fate, and

the trees struggling with each other for an existence. Now this may, at first sight, appear to many an imprudent way of managing things; as I believe I am within bounds when I say, that in a usual way, about twenty thousand Larch Trees are planted on an acre, and these never get either thinning or pruning; this, of course, at first sight, may puzzle those not versed in such matters, as they did my friend; but a very few words will explain all. Wood is a heavy, bulky commodity, and not easily moved great distances without incurring expenses beyond what its intrinsic value will repay; consequently, its greatest worth is on the spot where it is grown, provided a demand exists there. Now, in the case referred to, there is a demand, and a good one, for Larch poles of a certain size, as well as poles of other kinds of wood, but beyond that size or standard their value diminishes very much; hence, the propriety of cutting them at the precise period they are fit for market. I need hardly say, that Larch-trees, planted at distances not exceeding eighteen inches apart, speedily become drawn; and at the time when my friend saw them, they resembled, as he justly observed, a "forest of fishing rods;" some of the worst of the trees, probably, having had a bad start, had given up the struggle for existence, which the others competed for with all the energy, and not little of the selfishness, of a life and death struggle. This state of things puzzled my friend, who saw enough to convince him that edge tools were used pretty freely in the fruit plantation adjoining and elsewhere; however, he did not require much convincing of the profitable nature of the plan, which is this:—

The large extent of ground under cultivation as Hop-gardens, in Kent, and their consequent want of poles from ten to eighteen feet long, without any of the switch top, has, of course, led to a great demand for such articles, as some three thousand, or more, are wanted per acre, and these often wanting renewing, an active trade for such articles is kept up; and independently of the large quantity which a coppice of hard-wooded trees produces at each cutting, and of which I will speak hereafter, there has been a growing demand for Larch poles for many years, and many plantations of the kind above spoken of has been made of late, and many of these are made not by wealthy landlords with a view to ornamenting their estates, but by enterprising farmers and others, who look forward with some degree of certainty of being remunerated for their outlay, and in many instances the speculation has been a lucrative one; for on land of no great reputation, the produce of such a plantation often sells from fifty to seventy pounds per acre standing on the ground, the purchasers cutting and clearing it all away, and the seller, after grubbing the stumps up, which may cost (with the digging of the same) about £5 per acre, generally reaps good crops of corn afterwards from the change it has undergone, and by that routine of cropping, now so much practised, another piece undergoes the operation of planting, &c. I must not, however, forget to mention, that such a result is usually effected in about twelve years after planting, and sometimes it is less, if the ground be good, &c. As there is no attention whatever required after the first planting, save, perhaps, keeping the worst of the weeds down the ensuing season, the investment seems a favourable one, and on really good land I have known a ten-years growth produce eighty pounds per acre. Now, according to the pounds-shillings-and-pence-way of enforcing an argument, I question much if any other mode of growing trees of a forest kind present such a quick and profitable return; and I am not sure but a carefully-managed plantation of hard wood, cut periodically, be not equally a paying concern. Certain it is that timber is not so remunerative, for the old saying is, "that a coppice will buy the horse before the timber will

the saddle;" and though the remark be disheartening to those who so patriotically plant and clothe the country with its most befitting ornaments, yet it is too true, that as a crop, timber has almost ceased to be planted for remuneration, except in those inaccessible places where the husbandman cannot come, or where, for other reasons, he is not allowed to do so; but there are special cases, wherein trees are more profitable, and in a great many they are useful, but these, as well as other matters relating to coppices, &c., I must leave for another article; and in conclusion, would warn our young friends, when passing through an unknown country, not to jump too hastily at conclusions respecting the treatment of certain things, for, like the case above, it may be the very best in its way that could be adopted.

J. ROBSON.

THE FATTING OF SHEEP.

(Continued from page 344.)

IN continuation of the subject relating to the breeds of Sheep to be selected for fattening purposes, I must allude to the statement of Mr. Samuel Druce, given in the 31st No. of the "Journal of the Royal Agricultural Society of England," whose great practical experience in this matter must give it considerable weight and importance. The first important item in this statement is the comparative numbers of the different breeds of Sheep which may be kept upon the like quantity of food. The bulk of food requisite to fatten 100 Cotswold Sheep would fatten 105 Leicesters, 115 Hampshire Downs, 115 Sheep cross-bred between the Cotswold and South Down, and 120 pure South Down. The most important item which this statement furnishes is the comparative profit yielded by the same breeds in the value both of mutton and wool, and this will place them in the following order:—The Cross-bred Sheep give the greatest money return, the Hampshire Downs next, then the Cotswolds, the Leicesters, and last of all, giving the least profit, are the pure South Downs. Another statement upon this subject, based upon actual experiment, and carried out in the most elaborate and detailed manner, is by Mr. J. B. Lawes, and which will be found in the 28th No. of the same Journal, and must be taken as the most conclusive, it being the greatest combined effort of science and practice brought to bear upon the subject which has ever been offered to public notice, and the result is decidedly in favour of the Hampshire Down breed of Sheep, as compared with the pure South Down. Other statements and experiments may be adduced, but for the most part they point in the same direction. I must further say, that the above statement and experiment entirely support my own opinion upon the subject; and that after having given great attention to the fattening of Sheep, and having been a close observer of the best practices for a period of twenty-five years, I can, without any hesitation, confirm the above statements.

I cannot, however, entirely disregard the effect of soil and climate in this matter, and it would be no doubt difficult to state which breeds of Sheep are best adapted for fattening upon the different soils, but, in deciding this point, it is best not to overlook the breeds

peculiar to certain districts of the kingdom; and I may be here allowed to say, that in case any doubt arises in the mind of persons about to select a breed of Sheep for fattening purposes, they would do well to observe the prevailing breeds chosen by the most enlightened and experienced graziers of the locality.

In order that my readers may better understand the remarks I shall have to make, I propose to consider this subject as naturally divided into two departments, namely,—the winter fattening, and the summer grazing. I trust, also, that a few general remarks upon the purchase of stock will not be considered out of place. I cannot advise the buying of Sheep which are very poor, as it will always cost more to feed the Sheep up to tolerable condition than it will to purchase them in that state. Before you resolve to buy Sheep, endeavour to decide upon the age and breed of Sheep best suited to your soil and keeping; and in going through a fair for the purpose of purchasing, always select those which, in your own judgment, are best suited to your purposes; buy them as cheap as you can, but buy them, and remember that the purchase of stock merely because it is cheap (or what is called a bargain), must be characterised as folly, and that the likeliest lot to yield profit is that which you deem best suited to your requirements. I would further recommend that a warranty of soundness should be obtained, and no difficulty will be found in securing it; for I have never known parties hesitate in giving a warranty when they felt satisfied that it was not really required.

I must now proceed with the consideration of the first branch of the subject—the winter fattening of Sheep in the open field—for although I propose to make some remarks upon the comparative advantages of house and field-feeding, yet I must defer them until the conclusion of this article. The great increase in our population, and its requirements, has completely reversed the system of fattening Sheep; formerly their summer grazing was a matter of primary importance, but since the introduction of root-crops the winter fattening process has now become the most essential, both as regards the necessities of the consumer and the profits of the arable land farmer. Before the purchasing of stock takes place, calculate, as near as possible, how many can be kept, and the period you wish to finish root-feeding; and in case it is required to clear the land early for the purpose of sowing winter and spring wheat, the number of Sheep may be increased in the same proportion, and it will be necessary, in such case, to resort to artificial feeding, in order that the animals may be fattened in less time. Under ordinary circumstances, a fair rule to go by is that ten acres of turnips will fatten 100 sheep, supposing the crop to weigh about twenty tons of roots per acre, and that they receive as much of good hay as they will eat during the period of consumption. This, however, must in reality be only considered the starting point in feeding, for the consuming a given quantity of turnips may be made to extend over a great length of time, by the addition of feeding materials, such as oil-cake, corn, &c. In stocking a farm with

fattening Sheep, when the object is to consume the root-crop continuously from October to April inclusive, I do not hold it to be a good plan to purchase Sheep all of one age or condition; nor do I like the system of selling out all the stock at one period; I would prefer having some of them fit for market at an early period, and others later in the season. The advantage of this plan will be found in those winters when the roots are seriously damaged by frost, for in case of any great diminution of the root-crop, it is a matter of great consequence to have a portion of stock fit for sale, as the numbers of stock may then be adjusted to the keep, and the crisis passed over without loss. It is very desirable, upon those farms where a portion of grass-keeping can be made available, to purchase a portion of Lambs to be held on through the winter, and sold fat after shearing time, instead of purchasing a full complement of wether Sheep; and I consider that two-teeth Sheep are more profitable to fatten than four or six-teeth Sheep; for although it must be admitted that the older Sheep fatten quickest, yet the two-teeth Sheep grow, and yield a heavier weight of meat in proportion to the food consumed; indeed, it is now somewhat difficult to obtain, in any numbers, the four and six-teeth Sheep; early maturity being now the most prevailing idea, the greater portion of the Sheep are fattened as tegs or two-teeth. Before leaving the subject of ages of the stock for fattening, it is necessary to make some comparison of the difference between the keeping of Lambs and two-teeth Sheep; and in the case of stock purchased in the autumn for keeping through the winter, until shearing time, whether we view the question in relation to first cost, or expense of feeding, it is in favour of the Lamb; for it will be found, of a lot of Lambs and two-teeth Sheep, bought at the same price, that the former will realize the most money when sold out, supposing both to have been kept alike; and this arises from the great growth of the Lamb, and the value of its fleece, as compared with that of the two-teeth.

JOSEPH BLUNDELL.

(To be continued.)

VEGETABLES AND FRUIT OBTAINABLE IN FEBRUARY.

A CORRESPONDENT says, that "a monthly notice of this kind would be a valuable piece of information for the employer and the gardener, as it would show him what others can do." Now, I should place but little value on this kind of knowledge, as every gardener that is worthy of holding his situation will try and make the best of his circumstances. Hearing of what others do, and a stray remark from his employers, at times, will generally be sufficient to cause him to husband his means to the utmost. To a right-minded, intelligent, industrious man, it is anything but pleasing, or provocative of renewed effort, to be grumbled at because he does not get such-and-such things so early as Mr. A. or Mr. B., when the circumstances and the expenditure are things altogether different. There would be less unpleasantness in this respect, if employers did not expect impossibilities at times; and if our great gardeners did not unwittingly allow the idea to get into the mind of their aristocratic visitors, that such-and-such things involved but little trouble or expense. I have noted down in my memory as many facts illustrative of these remarks as would fill a large-sized volume,—facts which would show

that the blame was often put on the gardener when he did not deserve it. Allow me to give just a few illustrations.

A lady, surrounded by company, blamed her gardener in an exhibition-room because his plants were not by any means such nice and new things as those of Mr. B.; summing up with the finale, "I am sure the garden cost more than enough." I have often wondered how that lady would have looked, if the gardener had allowed his injured feelings as a man to get the better of his prudence as a servant, and then and there promulgated the fact—that for years there had not been five shillings spent either upon plants or seeds—even the vegetable seeds being all home-saved? A gardener, in these circumstances, would show discretion in never exhibiting.

Again, Mr. C. dines at Mr. D.'s in the month of March, and has Cucumbers for fish, and Radishes for salad, Mushrooms in all stages, young Potatoes, French Beans with mutton, and Strawberries for dessert. "Why cannot I have the same?" is the question put to blue-aproner the next morning, after seeing that there is no chance of his garden yielding him such dainties for weeks to come. "Why, Sir, you know you bound me down to have only that certain number of loads of dung; and what was the use of beginning early—I could not have kept things at all tender alive if I had commenced earlier." "Hang the dung; is not there that pit heated by hot-water: why should not I have Cucumbers in one part, Beans in another, and Strawberries in another, before commencing to force the Vinery?" "No reason at all, provided you allow fuel for the purpose; but didn't you tell me I must not use a particle more than that heap of dusty coal, which nobody else could burn, and these few chaldrons of coke, which will only be sufficient now if we have a nice sunny spring, but which I would have thoroughly consumed in a month or six weeks in severe weather in January or February?"

Is it necessary to increase such examples, or to say where such high expectations on the one side, and unequal resources on the other, are likely to end, save in mutual disappointment? A few months ago, I listened to a gentleman extolling to the skies two pits he had heated with hot-water, by means of one small boiler; and, no doubt, I rather pricked-up my ears, when he enthusiastically spoke of the small quantity of fuel necessary to raise the water to 200°, and how he could heat two, and, he had no doubt, three pits, with no more fuel than it would be required to heat one, all that was wanted being merely to make the water hot, and circulate it must. When, on being appealed to, I quietly hinted that I imagined a certain quantity of fuel would only give out a certain quantity of heat; and that, even when applied to water, although the heat was very equally diffused, the fuel necessary to raise and maintain a certain temperature would be in proportion to the quantity of water in the pipes, and the loss of heat from radiation to which they would be exposed; and that, consequently, two or three pits could not be heated by the same quantity of fuel as would be sufficient for one, while that quantity would just be increased in proportion to the disparity of temperature between the internal and the external atmosphere. I saw a look, which said as plainly as possible, "Oh! you know nothing at all about economising fuel;" while I felt what a miserable position the poor fellow would be in that was expected to have early fruit and vegetables in those pits, with his fuel measured out to him by the bushel; and I did this all the more, because circumstances have compelled me to try almost every possible means of economy in this direction, so much so, that I have often felt the buddings of envy at the condition of those near the mouth of a coal pit.

Let our friends rest assured, that unless, in these circumstances, or where opportunities present themselves for using the waste steam and hot-water from factories, &c., for accelerating vegetation, that early crops of fruit or vegetables must always be obtained at the expense of money, or money's worth and labour.

Vegetables from Open Garden.—Celery, Brussels Sprouts, Borecoles, of sorts; Savoys, Brocolis, Coleworts, Spinach, Leeks, young Onions, Horse-radish, Red Cabbage, Parsley, and other Herbs, White Beet.

Protected in Beds.—by the side of Walls or under Glass.—Parsley, Sorrel, Lettuce, Endive, and Cauliflower. *Dried Herbs* of all desirable kinds.

From Store Rooms.—Potatoes, Jerusalem Artichokes, Turnips, Carrots, Parsnips, Scorzoneria, Salsafy, Red Beet, Onions, Shallots, Garlic, Rocamboles, Chervil, &c.

From Forcing Ground.—Sorrel (green), Mint (green), Radishes, Asparagus, New Potatoes, Sea Kale, blanched Turnip-tops, Rhubarb Stalks, Mushrooms, blanched Chicory, Mustard and Cress, French Beans, Cucumbers.

Fruit from Fruit Room.—Apples, Pears, Medlars, Quinces, Walnuts, Chesnuts, Filberts, &c.

Fruit from Forcing Ground.—Pine Apple (at times), Oranges (at times, when cultivated), late Grapes, or early Grapes, and Strawberries.

R. FISHER.

RICH, YET POOR.

By the Authoress of "My Flowers."

A VERY solemn word is about to be spoken to us all in the following awfully affecting narrative. It has been furnished by the same kind hand that has sent so many words "in season;" but scarcely any circumstances of *real life* have met my observation so heart-rending, so terrible, as these!

"In the middle of a great thoroughfare in a large manufacturing town, in the north, may be seen a quaint old house and shop, which, like an aged, prejudiced person, seems to laugh at modern innovations, and to hold improvements in supreme contempt. For although its more presuming competitors have gradually taken tone from their neighbours, as one after another abandoned its small windows, and adopted magnificent squares of plate glass, yet the old house still retains its primitive simplicity—a large stone step standing at the door-way, and two old windows, which have occupied the same position for more than half-a-century, forming its frontage. The real cause of its retaining so venerable an appearance, however, is, in fact, the tight-handedness of its possessor—a man whose father carried on the same business successfully before him.

"John Scott, until the last year or two, was invariably at his post behind the counter; morning, noon, and night, might ever be seen his broad expansive countenance attending upon his customers, until a looker-on might really wonder when and how he contrived to spare time to satisfy the cravings of his appetite. To be 'not slothful in business' appeared to be Scott's guiding text, to the exclusion of every other in the Word of God; for the scraping together and laying up of gold seemed to be the aim and end of his existence; and money in large quantities he did get, and held it, too, with an iron grasp which nothing could loosen. No matter what inducement was held out—no matter how great the need for charitable assistance—Scott was not to be softened into charity. Families to whom he was deeply indebted for their assistance in the gathering up of his wealth might press upon him cares and the most distressing necessities; charitable institutions with bankrupt committees might plead the absolute need of immediate help to enable them to carry on their benevolent undertakings.—Scott was unmoved; not a sixpence would he give! and yet he was rolling in wealth!!

"Although his fellow-townsmen despised his penurious habits, and held him in contempt, yet they still frequented his shop, for the articles he sold could not elsewhere be procured so good, and were certainly far superior to any production of his rival manufacturers. Alas! that this man should have forgotten the many warnings of the Word of God, not to make gold our idol; and that he should not have remembered that 'to whom much is given, from him will much be required!'

"But did this accumulation of wealth really add to his happiness? Listen to the rest of my story, ye who receive liberally, and dispense with niggardliness, and take warning. John Scott, to the surprise of his neighbours, was seen less frequently behind his counters; on busy days even his absence was occasionally noticed—questions were asked, and unsatisfactory answers were given, without any particular reasons being offered. At last the truth was discovered—a kind of diseased state of feeling had gradually been creeping over him. He began, at first, to express fears that his household expenses were beyond what his

income would afford—the fear and alarm increased; he next fancied he should become a bankrupt. His friends endeavoured to laugh him out of such an absurd idea, but the feeling increased, and to such a degree that he feared the approach of bailiffs; and at last his fancies carried him to such a pitch that he refused to leave his bed, and became decidedly deranged in mind upon that one subject. There he lies now, a wretched, miserable man—dreading every tap at his door as the harbinger of the sheriff's officer—every visit of a friend as a messenger to convey him to the work-house. His business is carried on by his friends, and he is never expected to be able again to resume his labours.

"Is there no moral in this? Does it not speak to the covetous man in words not to be misunderstood? Alas! what object is more melancholy—more difficult to meet in social life without expressing disapprobation of it—than the niggardly man of ample means?"

Readers, it seems almost beyond the power of man to speak upon so terrible a history as this! It seems as if the narrative itself said everything. But I would beseech you to consider how it is with men when they "fall down and worship" the prince of this world! "All these things," saith the devil to the soul, "will I give thee, if"—*if only*—"thou wilt fall down and worship me." Behold the end, the *worldly* end, of such worship and such service! While the very meat is in their mouths, the wrath of God goeth forth and slays their enjoyment of it. All is turned to wormwood. Like the apples on the Dead Sea shore, the mouth that eats them is filled with dust and bitterness. Satan, that old serpent, has twined round their hearts, crushed their spiritual life, and now leaves them in mockery to reap according as they have sown. Oh! what a portion is it when we reap *corruption!*

Here is an instance—an appalling instance—of the vanity of riches. Poor John Scott still holds them; they have not been snatched from him; but yet they are lost to him: the Lord has blown upon them, and they have withered in his grasp; his power of enjoyment is cut off; he can discern them no longer. Solomon says, "There is a sore evil which I have seen under the sun; namely, riches kept for the owners thereof to their hurt." He also says, "There is an evil which I have seen under the sun, and it is common among men: a man to whom God hath given riches, wealth, and honour, so that he wanteth nothing for his soul of all that he desireth, yet God giveth him not power to eat thereof, but a stranger eateth it: this is vanity, and it is an evil disease." Indeed it is.

Poor Scott yet lives, and the day of grace may, therefore, not yet be passed. There is "balm in Gilead;" there is ointment to mollify the deadliest sore; there is a medicine that can draw out even the sting of death! Is he wholly dead to things of sense? Might the Gospel sound still touch an unbroken chord in that poor, jangled mind! Nothing else can save body or soul; but the healing leaves of "the tree of life" might yet be laid to the soul, and it might arise and sing! He who was "wounded for our transgressions, and bruised for our iniquities," is ready and willing to save; and nothing can so effectually restore a diseased and disturbed mind as the soothing and sweet sound of Jesus' message to lost sinners.

Readers, let us "beware of covetousness, which is idolatry." Let us "use riches, as not abusing them" or they will "pierce us through with many sorrows." They are God's, and not our's, even when poured into our lap; we are only stewards, and if *unjust* ones—if *niggardly* ones—laying up, instead of laying out—REMEMBER!

CITY OF MANCHESTER EXHIBITION OF POULTRY.

ALTHOUGH behind many other localities, Manchester appears to have determined, when it did begin, to commence in earnest; and when we state that this, their first Show, numbered upwards of 900 pens, we may well congratulate the amateurs of the neighbourhood on their first success. The meeting was held on the 24th and 25th of January, in the "Free Trade Hall," a place in which other sounds than the crowing of cocks were wont to have been

heard. The building is sufficiently spacious, including the galleries, for a very large display of poultry, but having been adapted for gas-light use, it is unfortunately not provided with sufficient windows to light it effectually in the day-time, especially at this dull season of the year. Some temporary openings had been made to remedy, in some degree, this defect; but still there was not light enough to show the birds to advantage.

But even with this drawback the exhibition was a good one, for the Committee, headed by their chairman, Mr. Wanklyn, had made excellent arrangements for the reception and care of the specimens, and for the accommodation of the subscribers and spectators; and the area of the building was, moreover, large enough to enable them to have all their pens placed on a level, and covered with wire netting, so that all the light which the place afforded was made available, and the unfairness so much and so justly complained of where specimens are placed at different heights was avoided. In the body of the Hall, the pens were arranged in rows, with broad alleys between them; on the platform were three more rows of pens, and two rows extended around the galleries. The *Turkies*, *Geese*, and *Aylesbury Ducks*, were penned in a small adjoining building, communicating with the Hall; and a refreshment-room, with offices for the secretary and his staff, completed the arrangements.

Whether as regards quantity or quality, the Show, as a whole, may be safely pronounced highly creditable both to the promoters and exhibitors. The classes, as is always the case, were somewhat unequal in point of merit; but in most, if, indeed, not in all of them, some good specimens were shown, and in several there were few had ones. A wet morning rather thinned the company on the Tuesday; but the weather cleared-up as the day advanced, and the Hall soon became thronged with a company so numerous as to show that the prevailing taste for poultry had not failed to extend itself even to the metropolis of our manufactures.

In offering a brief commentary on the different classes the *Spanish* first claim our attention. These were arranged in three classes, numbering together 70 pens, and comprising some of the best birds the kingdom can produce. The coloured *Dorkings*, also, were numerous and highly meritorious, Capt. Hornby carrying off the principal prizes in all three classes. The *Cochins* had some good specimens, but we do not think that they were equal, in the whole, either to the *Spanish* or *Dorkings*. There were a few pens of good *Malays*, but nothing deserving especial notice. The *Game* classes did not muster so strong as we should have expected, but among them were some very fine specimens of this truly English fowl,—in our opinion, the handsomest to look at, and the best for the table, of all the varieties of our domestic poultry. The *Hamburghs* came next, and were fairly represented; but there was nothing very remarkable amongst them, if we except the pen of silver-spangled chickens, to which the first prize in their class was awarded and which were among the very best we ever saw. The *Polands* were both numerous and good, and some of the classes received the commendations of the Judges collectively. Those attractive little favourites, the *Bantams*, were also in good force, and added their mite to the interest of the feathered fowl. A class which we do not remember to have seen before came next, being for “a cock and hen more than one year old, of any variety,” and in it no less than five prizes were offered. This brought together some very fine specimens of almost every variety, and resulted in the first prize being carried-off by a splendid pair of Capt. Hornby's *Spanish*, the two next by *Dorkings*, the fourth by Dr. Gwynne's *Brahma Pootras*, and the fifth by a fine pair of *Andalusians*. The next classes were for single cocks of the different varieties, and they brought together an assemblage of good, bad, and indifferent, in which the latter quality appeared to us to predominate. The *Geese* were not numerous, but there were a few good pens among them. The *Ducks* exhibited nothing very remarkable in point of quality. There were some very fine *Turkies*, the three which obtained the first prize weighing together 54 lbs. A few good pens of “extra stock,” comprising several varieties, and including a pair of the finest *Turkey Poults* we ever remember to have seen, completed the list of 913 pens,

forming together an exhibition of which an older society might justly be proud.

From a very competent Correspondent we have the following additional notes:—

“A new feature (and among the exhibitors of first-class birds it proved a *most popular one*) was the positive prohibition of sticks, umbrellas, or parasols, in the hands of visitors, all being left in the care of a party provided to take charge of them till the owners were about to leave; the *only exception* being in favour of the Judges. By this arrangement the comforts of the imprisoned poultry were readily ensured, and not only was the noise occasioned by the screaming of alarmed fowls greatly lessened, but it was pleasing to see the air of quiet contentment that reigned throughout; it would be well if the same course was adopted generally, for much of the *after* indisposition, so much complained of in fowls returned from exhibitions, no doubt proceeds from the *constant* state of irritation kept up by the perpetual violence of thoughtless visitors. I must give the highest credit to the general management and peculiar cleanliness of the exhibition, and the really untiring efforts of all the committee to carry out all their plans with order and regularity.

“In speaking of the different classes, the *Spanish*, as usual, took precedence on the catalogue; *here*, too, they did most undoubtedly take precedence of every collection of this variety that has competed at public exhibitions, the rivalry and competition being very far beyond the aggregate; the avenue appropriated to this variety seemed quite the most popular, while many and urgent were the disquisitions here held on the individual merits of particular pens. When it is stated that the far-famed pens of Capt. Hornby, whose oft-repeated successes have been so frequently blazoned in the public prints, here had to doff their laurels to a newcomer, some little idea of the severity of the struggle for mastery in this class may be imagined.* The first prize were, undoubtedly, the best-conditioned fowls we ever saw, and all the most fastidious could desire. In the *Spanish*, Capt Hornby secured no less, however, than three first, a second, and a third prize; whilst in coloured *Dorkings* the superiority of that gentleman's strain was fully apparent,—three first, three second, and a third prize being awarded. Of the coloured *Dorkings* it is impossible to speak more highly than their due, for not only were they in excellent condition, but the most closely matched that we have yet seen. The *White Dorkings* were really but little worthy of admiration; for though a few pens were exceedingly good fowls, they presented that “uncared-for” appearance, the very opposite of what should exist in birds where the competition is a good one, if their owners entertain reasonable desire for success. I felt quite astonished at the obvious degeneracy of the *Buff Cochins*, for though in point of numbers there was nothing to complain of, I in vain looked for those special favourites that were so deservedly coveted in former days; this it is difficult to account for, except from the fact of too great attention being given by breeders generally to colour, to the almost complete neglect of more *essential* characteristics. The *Black* class, too, was very indifferent, as also the *Partridge-feathered*, and in each section many prizes were, therefore, withheld. In *White Cochins* some very excellent pens were exhibited, and the fowls of G. Peters, Esq., of Birmingham, were exceedingly successful. In the *Game* classes the competition was necessarily very closely contended, this breed of fowls having been, for more than two centuries, the most carefully managed in the surrounding districts of any part of the United Kingdom: “the old Derby breed” (of black-breasted reds) having, in the days when the cruel practice of cock-fighting was in the ascendant, proved their capabilities in the cockpit of superiority, as they now did in the exhibition-pen. Never were there more beautifully-feathered, highly-conditioned, or perfect specimens brought into competition.

“In *Amateur Prizes* (the award being to a single cock), the specimens were deserving of all praise, and found ready purchasers at liberal prices,—one twelve guineas,—on which a very considerable advance was afterwards offered to the purchaser, but refused. Several other single birds were also eagerly sought for by amateurs, so that most changed hands.

* It is but fair to state that Capt. Hornby's pen of best birds were not there.

The White Aylesbury and Rouen Ducks mustered strongly, and showed in good feather; but in the latter variety, the deterioration, both in form and colour, from such as a few years back figured A 1 at the Birmingham Shows, and again and again were subjected to the ordeal of the scales by the judges, and varied from 26½ lbs. to 31 lbs. the four, according to their condition, convinced the most sceptical that *new blood* is here wanting, for certainly *great size* was (with the colours of the pure Wild Duck) indicative of *original purity*, and ought, if possible, to be maintained."

The Judges were E. Bond, Esq., Leeds; T. Challoner, Esq., Worksoy; E. Hewitt, Esq., Birmingham; W. Symonds, Esq., Weymouth; and W. Trotter, Esq., Newcastle-upon-Tyne.

We annex the list of prizes awarded by the Judges:—

Class 1.—SPANISH.—*Cock and two Hens*.—14. First prize, John Harrison, jun., Snelston Hall, Derbyshire. 3. Second prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 7. Third prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. Class 2.—*Cockerel and three Pullets*.—30. First prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 38. Second prize, Daniel Parsons, Cuerden, near Preston. 47. Third prize, William Ellison, jun., Low Sizergh, near Blinthorpe. Class 3.—*Cockerel and one Pullet*.—49. First prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 51. Second prize, Henry Openshaw, Oak Hill, Prestwich, near Manchester. 53. Third prize, G. W. Hardy, Warrington.

Class 4.—DORKING (White).—*Cock and two Hens*.—78. First prize, Joseph Jenkens, Moseley, Birmingham. 74. Second prize, George Fell, Springfield, Warrington. 77. Third prize, Francis Edwards, Bulstrode Park, Buckinghamshire. Class 5.—*Cockerel and three Pullets*.—79. Second prize, Christopher Rawson, The Hurst, Walton-on-Thames.

Class 6.—DORKING (Coloured).—*Cock and two Hens*.—88. First prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 92. Second prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 94. Third prize, E. Lister, Cassia Lodge, near Over, Cheshire. Class 7.—*Cockerel and three Pullets*.—104. First prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 98. Second prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 116. Third prize, Mrs. Thomas Townley Parker, Asley Hall, Chorley.

Class 8.—DORKING (Of any colour).—*Cockerel and one Pullet*.—119. First prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 136. Second prize, E. Lister, Cassia Lodge, Over, Cheshire. 129. Third prize, Daniel Parsons, Cuerden, near Preston.

Class 9.—COCHIN-CHINA (Cinnamon and Buff).—*Cock and two Hens*.—145. First prize, Mrs. Ambler, Watkinson Hall, near Halifax. 160. Second prize, Mrs. Lydia C. Stow, Bredon, near Tewksbury. 144. Third prize, George C. Adkins, Edgbaston, Birmingham. Class 10.—*Cockerel and three Pullets*.—193. First prize, Mrs. Ambler, Watkinson Hall, near Halifax. 171. Second prize, H. W. Collinson, 47, Castle-street, Southwark. 239. Third prize, Miss Rachel Walker, Clipston Rectory, Northamptonshire.

Class 11.—COCHIN-CHINA (Brown and Partridge-feathered).—*Cock and two Hens*.—260. Second prize, George C. Adkins, Edgbaston, Birmingham. 261. Third prize, Colonel Clowes, Froxiner Court, Worcestershire. Class 12.—*Cockerel and three Pullets*.—270. Second prize, William Wanklyo, jun., Greenbank, Bury. 272. Third prize, Thomas Bridges, Croydon, Surrey.

Class 13.—COCHIN-CHINA (White).—*Cock and two Hens*.—291. First prize, George C. Peters, Charlton Cottage, Moseley, near Birmingham. 292. Second prize, Benjamin Holmes, 112, New-street, Birmingham. 288. Third prize, George Boothby, Holme Cottage, Louth, Lincolnshire. Class 14.—*Cockerel and three Pullets*.—317. First prize, George C. Peters, Charlton Cottage, Moseley, near Birmingham. 316. Second prize, George C. Peters, Charlton Cottage, Moseley, near Birmingham. 294. Third prize, Christopher Rawson, The Hurst, Walton-on-Thames.

Class 15.—COCHIN-CHINA (Black).—*Cock and two Hens*.—324. Second prize, Henry Parker, Church Lane, Hadsoworth, near Birmingham. Class 16.—*Cockerel and three Pullets*.—326. First prize, William Wanklyo, jun., Greenbank, Bury. 328. Second prize, W. C. Gwynne, M.D., Sandbach, Cheshire. 325. Third prize, Mrs. Lydia C. Stow, Bredon, near Tewksbury.

Class 17.—COCHIN-CHINA (Of any colour).—*Cockerel and one Pullet*.—341. First prize, Henry Ambler, Watkinson Hall, near Halifax. 383. Second prize, George C. Peters, Charlton Cottage, Moseley, near Birmingham. 368. Third prize, Charles Bainbridge, 16, Old Meeting-street, Birmingham.

Class 18.—MALAY.—*Cock and two Hens*.—393. First prize, Gervase Oldham, Whitacre, near Colchill, Warwickshire. 396. Second prize, Gervase Oldham, Whitacre, near Colchill, Warwickshire. Class 19.—*Cockerel and three Pullets*.—401. First prize, Gervase Oldham, Whitacre, near Colchill, Warwickshire. 403. Second prize, Gervase Oldham.

Class 20.—GAME FOWL (White and Piles).—*Cock and two Hens*.—404. First prize, W. and J. H. Parkes, Wellington Place, Highgate, Birmingham. 406. Second prize, Francis S. Bulluck, Handsworth, near Birmingham. 410. Third prize, Rev. Thomas Lyon Fellows, Beighton Rectory, Acle, Norfolk. Class 21.—*Cockerel and three Pullets*.—417. First prize, Arthur Dakin, Birmingham. 413. Second prize, Henry Ambler, Watkinson Hall, Halifax.

Class 22.—GAME FOWL (Black-breasted and other Reds).—*Cockerel and two Hens*.—418. First prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 430. Second prize, Robert Brookhouse, Cheadle, Cheshire. 433. Third prize, Sam Armitage, Thornton-road,

Bradford. Class 23.—*Cockerel and three Pullets*.—436. First prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 438. Second prize, Geo. C. Adkins, Edgbaston, Birmingham.

Class 24.—GAME FOWL (Black and Brassy-winged, except Greys).—*Cock and two Hens*.—450. First prize, Joseph Jenkens, Moseley, Birmingham. 451. Second prize, Sam Armitage, Thornton-road, Bradford. 449. Third prize, Samuel T. Smith, Madeley, Shropshire. Class 25.—*Cockerel and three Pullets*.—456. First prize, Samuel T. Smith, Madeley, Shropshire. 457. Second prize, Joseph Jenkens, Moseley, Birmingham.

Class 26.—GAME FOWL (Duckwings and other Greys and Blues).—*Cock and two Hens*.—459. First prize, Mrs. Ambler, Watkinson Hall, near Halifax. 460. Second prize, Sam Armitage, Thornton-road, Bradford. 462. Second prize, Henry Worrall, Knotty Ash House, Liverpool. Class 27.—*Cockerel and three Pullets*.—468. First prize, Dan Leeming, Blackwood House, Halifax. 471. Second prize, John Adwen, Kebroyd, near Halifax.

Class 28.—GOLDEN-PENCILLED HAMBURGERS.—*Cock and two Hens*.—481. First prize, Josiah B. Chune, Croakdale, Shropshire. 474. Second prize, Captain Windham Hornby, Knowsley Cottage, Prescot. 483. Third prize, Charles John Mold, Wingfield Park, Belper. Class 29.—*Cockerel and three Pullets*.—491. First prize, Henry W. Heaton, Copley Wood, near Halifax. 493. Second prize, Rev. Thomas Lyon Fellows, Beighton Rectory, Acle, Norfolk.

Class 30.—GOLDEN-SPANGLED HAMBURGERS.—*Cock and two Hens*.—504. First prize, James Dixon, Bradford. 499. Second prize, George C. Adkins, Edgbaston, Birmingham. 496. Third prize, Joseph Thorpe, Symister Lane, near Middleton. Class 31.—*Cockerel and three Pullets*.—526. First prize, George Fell, Springfield, Warrington. 516. Second prize, John Andrews, Waterhouses, Ashton-under-Lyne.

Class 32.—SILVER-PENCILLED HAMBURGERS.—*Cock and two Hens*.—546. First prize, James Dixon, Bradford, Yorkshire. 537. Second prize, M. H. Broadhead, Stubbin, Holmfirth, Yorkshire. 531. Third prize, Jeffery Ashcroft, Waterloo, near Ashton-under-Lyne. (Cottager.) Class 33.—*Cockerel and three Pullets*.—549. First prize, Thomas Haslam, Symister Lane, near Middleton. (Cottager.) 555. Second prize, Joseph Crossley, Lane Top, Sutton, near Cross Hills, Yorkshire.

Class 34.—SILVER-SPANGLED HAMBURGERS.—*Cock and two Hens*.—569. First prize, James Dixon, Bradford, Yorkshire. 561. Second prize, Jeffery Ashcroft, Waterloo, near Ashton-under-Lyne. 565. Third prize, H. M. Broadhead, Stubbin, Holmfirth, Yorkshire. Class 35.—*Cockerel and three Pullets*.—588. First prize, Matthew Hedley, Higher Broughton, Manchester. 576. Second prize, Thomas Hall, Denton Lane, Fox Denton, near Oldham. (Cottager.)

Class 36.—POLAND FOWL (Black, with White Crests).—*Cock and two Hens*.—597. First prize, George C. Adkins, Edgbaston, Birmingham. 604. Second prize, John T. Hildbert, Urnston, near Manchester. 598. Third prize, Joseph Conyers, 42, Boar Lane, Leeds. Class 37.—*Cockerel and three Pullets*.—609. First prize, Francis Edwards, Bulstrode Park, Buckinghamshire. 611. Second prize, Mrs. C. H. Horsfall, Duffield Bank House, Derby. (The class commended.)

Class 38.—POLAND FOWL (Golden).—*Cock and two Hens*.—613. First prize, Christopher Rawson, The Hurst, Walton-on-Thames. 621. Second prize, S. C. and C. N. Baker, Half-moon Passage, Gracechurch-street, London. 617. Third prize, Joseph Conyers, 42, Boar Lane, Leeds. Class 39.—*Cockerel and three Pullets*.—632. First prize, James Whitaker, Clare Hall, Huddersfield. 627. Second prize, William Cox, Brailsford Hall, Derby.

Class 40.—POLAND FOWL (Silver).—*Cock and two Hens*.—638. First prize, James F. Greenhall, Crapenham Hall, Warrington. 635. Second prize, Christopher Rawson, The Hurst, Walton-on-Thames. 640. Third prize, George C. Adkins, Edgbaston, near Birmingham. Class 41.—*Cockerel and three Pullets*.—646. First prize, W. G. Vivian, Singleton, Swansea.

Class 42.—BANTAMS (Gold-laced).—*Cock and two Hens, or Cockerel and Pullet*.—652. First prize, George C. Adkins, Edgbaston, Birmingham. 656. Second prize, Mrs. Hosier Williams, Eaton Mascott, Shrewsbury.

Class 43.—BANTAMS (Silver-laced).—*Cock and two Hens, or Cockerel and Pullet*.—664. First prize, George Boothby, Holme Cottage, Louth, Lincolnshire. 665. Second prize, Mrs. Hosier Williams, Eaton Mascott, Shrewsbury.

Class 44.—BANTAMS (Black).—*Cock and two Hens, or Cockerel and Pullet*.—670. First prize, Gilbert Winter Moss, Liverpool. 674. Second prize, Gilbert Winter Moss, Liverpool.

Class 45.—BANTAMS (White).—*Cock and two Hens, or Cockerel and Pullet*.—678. First prize, George C. Adkins, Edgbaston, Birmingham. 687. Second prize, Edward Alison, jun., Park Hall, near Chorley.

Class 46.—BANTAMS (Any other variety).—*Cock and two Hens, or Cockerel and Pullet*.—690. First prize, Mrs. Hosier Williams, Eaton Mascott, Shrewsbury. 699. Second prize, George C. Adkins, Edgbaston, Birmingham.

Class 47.—COCK AND HEN.—*More than one-year-old of any variety*.—707. (Spanish.) First prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 697. (Dorking.) Second prize, Mrs. Thomas Townley Parker, Asley Hall, Chorley. 701. (Dorking.) Third prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 706. (Brahma Pootra.) Fourth prize, W. C. Gwynne, M.D., Sandbach, Cheshire. 710. (Andalusian.) Fifth prize, Colonel Clowes, Froximer Court, Worcestershire.

Class 48.—AMATEUR PRIZES.—*Cocks of any age*.—741. For the best single Spanish cock. E. W. Willmot, Ilkley Warfield, Conkinton. 746. For the best single Cochin cock. Robert Brookhouse, Cheadle, Cheshire. 773. For the best single Dorking. John Staley, North Chillingham, near Newark. 779. For the best single Game cock. James Fletcher, Ringley, near Bolton. 793. For the best single Hamburg cock. James Parlington, Symister Lane, near Middleton. (Cottager.)

Class 49.—*GESE*.—*Gander and two Geese*.—801. First prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 807. Second prize, William Charlton, Seelley. 804. Third prize, Mrs. Thomas Townley Parker, Astley Hall, Chorley.

Class 50.—*Ducks* (White Aylesbury).—*Drake and three Ducks*.—810. First prize, Christopher Rawson, The Hurst, Walton-on-Thames. 827. Second prize, Mrs. Lydia C. Stow, Bredon, near Tewsbury. 815. Third prize, John Hunt, Barrow, near Ulverston.

Class 51.—*Ducks* (Rouen).—*Drake and three Ducks*.—834. First prize, Henry Worrall, Knotty Ash House, Liverpool. 839. Second prize, R. E. Ashton, Ramsbottom, near Bury. 836. Third prize, Thomas Statter, Stand Hall, Pilkington.

Class 52.—*Ducks* (Of any other variety).—*Drake and three Ducks*.—847. First prize, Henry Worrall, Knotty Ash House, Liverpool. (Call Ducks.) 848. Second prize, Miss Clifton, Whittington, near Worcester. (Black East Indian.) 861. Third prize, William Hodgkinson, Gough Hill, Birmingham. (Muscovy.)

Class 53.—*TURKEYS*.—*Turkey Cock and two Hens*.—871. First prize, Joseph Conyers, 42, Boar Lane, Leeds. 866. Second prize, Captain Windham Hornby, R.N., Knowsley Cottage, Prescot. 870. Third prize, E. H. Wilmot, Hulme-Warfield, Congleton.

EXTRA STOCK.—899. Prize. Rev. Thomas Lyon Fellowes, Beighton Rectory, Acle, Norfolk. (Black Hamburgs.) 909. Prize. Thomas Whittington, jun., Wooton Wawen, near Henley-in-Arden. (Andalusian.)

ST. LAWRENCE VINEYARD.

AMONGST the many establishments worthy of the horticulturist's attention in the Island of Jersey is a Vineyard situate on the south-western side of the island, and on the same side of the St. Lawrence Hill, about two and a half miles from the town of St. Helier's, and overlooking the beautiful Bay of St. Aubin's, the property of a very worthy and spirited gentleman, who has devoted much of his time, during the last seven years, in turning a "barren cōtil and furze bank" into a valuable and profitable piece of property. The crops now produced being turned to very good account, through the many advantages the peculiar position of the property offers, and the good judgment which has been displayed by the proprietor in availing himself of those advantages.

The whole area of this establishment is about two English acres, which is terraced and faced according to the facing of the hill slope. S.E. and S.W., but principally S.W., the upper portion of which is covered with glass constructions, which are devoted exclusively to the cultivation of the Vine; the measured length of which is more than half a mile; which are heated with boilers and hot-water pipes of Messrs. Burbidge and Healy's construction; the capacity of which system is more fully developed here than in any other establishment I have had the advantage of visiting; for the pipes, in several instances, are fixed on an inclined plane, and owing to the irregularity of the surface of the ground, the extreme ends of the pipes are many feet above the level of the boilers, and the houses being from two to three hundred feet long, the water in the pipes has to flow a great length up hill before it reaches the return pipe to the boiler; and the pipes at the extreme end, near the expansion box, are often much warmer than nearer the boiler, maintaining in the whole a beautiful and congenial heat throughout the house or houses, which are, of course, heated in compartments, and by different boilers.

The worthy proprietor, who feels much interested in the cultivation of the vine, himself devotes much personal attention to the manner in which the manual labour is performed, and the result of such attention must be very gratifying to him, for the crops produced during the seasons 1852 and 1853 have been prodigious, and have surpassed all expectation, five to six tons of well-coloured and finely-flavoured grapes having been cut in 1852, and seven to eight tons in 1853; the greatest portion of which have been sold in the London markets, realizing a good profit to the salesman; a living to the individual employed in conveying them to and fro, in his capacity as "middleman;" and remuneration, with interest, to the employer and proprietor for his outlay and incidental expences; who has, on the other hand, the gratification of employing, advantageously, several hands in attending to the houses, Vines, grounds, &c., and preparing the fruit for the market. So much for the wise application of leisure time, at a leisure period of life; the proprietor being a man in easy circumstances, inde-

pendent of the establishment, which has been a source of recreation and amusement, during the last few years, to his ingenious and persevering mind, and now proves a valuable investment of capital, independent of the moral source of gratification arising from the amount of good it does to others; and the proof that, "Without steadiness of purpose no real good can be realized."

But again, there are many things which would take a thoughtful gardener's (either amateur or professional) attention in walking over this establishment. One striking peculiarity is, that more than half of the Vines are planted in the borders at the backs of the houses, which are on a level with the top of this wall, and are trained down the rafters instead of up, which, to reason, seems the actual perversion of Dame Nature's laws respecting the flow and descent of sap; but whether it is the nature of the dressing given to the borders, the natural vigour of the Vine, or the mode of pruning and management (each plant not being allowed more than a single rod, which is most unmercifully stumped in every season, not allowing a spur or an eye to remain visible, and then being painted over with a coat of "lime, soft soap, and sulphur vivum mixed," to boot), I know not; but the Vines seem to thrive well under it, and they are close or short-jointed, and when excited to growth in winter or early spring; December, January, and February, being the periods at which they are started, so as to ripen the fruit in rotation, they break at the joints or bends of the wood, with three, four, and five eyes or shoots, giving striking evidence of health and vigour; the strongest one or two of these shoots are allowed to remain, according to the requirements of that particular part of the roof, and the remainder are rubbed off with the thumb.

These being the two most marked peculiarities respecting the culture of the plants themselves, which are principally of the *Black Hamburg* and *Muscat of Alexandria* varieties, it would be wasting most of your readers time to recapitulate the whole process of Vine culture. We all know, or think we know, a good deal about these simple things, and "Mr. Annus," having been the first pruner of vines, or having accidentally nipped off the tops of the young shoots, and attracted man's attention to what he had not before noticed, I must leave to more able heads and hands the development of the aforementioned personage's theory, merely specifying, that the topping of the young shoots, and the thinning of the berries on the branches, is here performed with far less ceremony and expenditure of time than is usually bestowed on such operations.

The Grapes ripen very early here, being in abundance during the months of May, June, and July, and the Vines are then drawn out of the houses, or the lights are taken off, after the fruit is gathered, so as to perfect the development of the plants growth for the season, to ripen the wood and prepare the plants to be resubjected to similar treatment the ensuing year.

It was a question in my mind, for some years after seeing this practice commenced, "That turning the Vines downwards could not possibly answer for any length of time;" and I do not doubt that many of your readers may enter into the same line of thought. I considered that "Art might assist Nature; but that the perversion of Nature's ways must end in disappointment." Such were my thoughts; but here we may see the perversion of Nature made Nature's assistant, and turned to the best possible account, by answering all the purposes required of it. Shortness of joint in wood, prolific bearing, apparent health and vigour of plant, whilst the foresight displayed in so planting them provided a body of good mould between the back wall and the slope of the hill, for the nourishment and support which could not have been obtained by equally easy and convenient means in any other way in this particular locality.

As it may be readily supposed, there is a large quantity of rain falls on the roofs of such a surface of houses and sideling ground; and that the run of such quantities of water would be highly injurious to the terraces and property beneath; this the proprietor has prepared himself to meet by having a number of large circular cisterns built on the surface of the grounds with bricks and cement, to receive the water from each of the roofs, each of which is supplied with a large watercock, at or near the bottom, which is turned on when the rains are heavy, and these cisterns

falling so that the overplus water may be conveyed through pipes to the lower terraces, and thence to one immense cistern. By these means, all the rain falling, which could in any way be injurious to the property, or among the neighbours below, is saved, and may, should circumstances require it, be forced up to the highest part of the premises, to water the Vine borders, &c.

I should have said enough respecting this ornamental and useful place to have called the attention of all horticulturists towards it, but I cannot stop yet; my thread is not run out; and here I must inform your readers, I have seen *Haarhornden* and *Ribston Pippin* Apples ripe in August; Apricots by hundreds; Plums and Pears by bushels; and small fruit by the ewt. Enough fruit is now grown on this cold and once barren piece of ground to supply a whole regiment, 1000 strong, and every man to have as much as would do him good during the season, besides flowers growing and thriving in the most exuberant state. Here I recollect seeing *Digitalis purpurea*, or the Foxglove, growing in the most beautiful variety, from pure white to the original purple, and some with the most beautifully spotted throats in almost every intermediate shade; the central spikes of bloom being from seven to eight feet high, with from thirty to forty minor and lateral shoots, making altogether the most splendid pyramids of bloom that can possibly be imagined. The *Double Yellow Provence Rose* also thrives well here a very strong plant; growing at the foot of one of the flights of steps, producing abundance of splendid, large, yellow flowers, as large and as double as the *Old Provence Rose*. This seems to be a peculiar plant, outwitting the most witty of gardeners as to the best mode of cultivating it. It seems as if it would only grow where it liked. Here it thrives in the greatest luxuriance and beauty. The Fuchsias, Pæonias, Roses, and most other flowering shrubs and plants may here be seen thriving with the same luxuriance of growth and abundance of bloom. I would recommend all the lovers of horticulure and floriculture visiting the Island of Jersey not to leave it without endeavouring to make time for a visit to this establishment.—C. B. S., *Jersey*.

BANTAMS AS RECENTLY SHOWN.

(Concluded from page 345.)

WHATEVER the causes to which we should assign the falling off in the "laced" birds that we recently complained of, it is satisfactory to observe that other varieties have, at the same time, more than held their own. In the "black" Bantam Class, for instance, birds of the highest merit have been abundant, and both at Leeds and Birmingham pens of these birds have been shown in the year just passed that would have stood the severest criticism, and it may be fairly said, that throughout the regions of Poultry Shows these have been eminently good. No complaints are heard of the unfertile character of the black Bantam's eggs, hardy, vigorous little balls of dark fluffy down are always abundant, and neither in chickenhood or maturity, under ordinary care, need we feel anxious about their well doing. But all this is widely different to what takes place with the subjects of our last paper, viz., the laced birds, both gold and silver. Yet this might well be expected, since, in the last case, the characteristic features of the healthy male bird are deemed blots and blemishes, and our anxious and continued efforts are devoted to their eradication as far as our powers go. But look at the parent of our black Bantam brood—a vigorous, high-conraged little fellow, with so much masculine energy as enables him to lord it over fowls twice his size, and possessing his male attire as brilliantly relieved from that of his mate as we find in black fowls of any kind.

The tail is here left an open question, since, although there are many by whom the preference would be given to one of rather a square character, no one, we think, should find fault with the most ample sickle-feather, provided there be no undue excess of size or loss of symmetry. Another point, on which we have heard various opinions expressed, concerns the ear-lobe, which, to our own eye, appears best when white, or but slightly blushed; good

judges, however, are found who do not object to its being red, but when this is the case, the loss of the contrast, so strongly exemplified in the black Spanish, or the black Hamburg, seem to deteriorate from the general effect.

"White" Bantams, also, have progressed rapidly of late, and the coarse birds that were frequently seen in former years, more allied apparently to the white Dorking than belonging to the family we are now speaking of, are rarely thrust forward for judicial disapprobation. The July Exhibition, at Plymouth, had some excellent birds in this class, perfect in form as well as feather; and at Birmingham, also, they came forward with equal credit. Here we first come to a question relative to the "comb," for in the laced and black varieties there can be no question but that that appendage should be in the rose form. The single comb, however, is said to be admissible in white Bantams, though, whenever it is substituted for the former, the bird appears to disadvantage, in our eyes, to fully the same extent as with the white Dorking. The compactness of the rose-comb harmonises with the general character and form of these diminutive birds; and both here, as in the case of other rose-combed fowls, the intensity in colour of the comb appears to exceed that of single-combed specimens. May not this be, perhaps, attributable to the formation of the first so clearly resembling the coral, from which we are accustomed to derive an epithet for the comb generally? Be this as it may, our verdict goes unhesitatingly for rose-combed white Bantams, though admitting the excellence in other points of very many single-combed pens that have been recently exhibited.

Considerable surprise was felt by many exhibitors at a decision in the Bantam classes at the recent Metropolitan Exhibition. We allude to the first prize awarded to a pen of "booted and tufted white Bantams," which were placed over the head of several pens of the clean-legged birds, to which last custom has hitherto limited the class in question. According to the wording of the prize-list, the Judges might have felt themselves bound to award the prize to any birds of that "colour" that might seem to them best to deserve the honour; and, in saying this, it must be remembered that we are not here discussing the question of whether they were the best birds of their class, or not; but, simply, whether they were admissible, or otherwise. The clean-legged white Bantam has, unquestionably, been generally considered as the best form of that bird, and nothing of recent introduction has induced us to change that opinion. The "booted" birds have, also, during the past year, been assigned, in many instances, a separate class, where the birds possessing this peculiarity, no matter of what colour, should all be arranged. The fact of prizes for "booted, or feathered Bantams" would at once disqualify such specimens when shown in the other classes that have previously been occupied exclusively by the clean-legged birds; but it is by no means equally clear that the former would be necessarily included among those "of any other variety."

Beyond the four varieties already enumerated, the competitors for fame among the other Bantams were, till the last year or so, comparatively scarce; nor, indeed, were the merits of such as did appear sufficient to make us anxious for their further acquaintance. The period over which this remark is extended is not designed to go back to those times, now some twenty or thirty years back, when the booted Bantams, and the unfortunate Creepers and Jumpers were, among others, objects of popular favour; but we refer only to the later epoch of Poultry Exhibitions, dating, perhaps, from their first inauguration at Birmingham. Among the miscellany that the class for odds and ends frequently submits to our notice, the "Spangled" birds are frequently seen, but these are rarely satisfactory, too commonly reminding us of imperfect lacing, which is degenerating into spottiness, rather than showing the clear ground colour and distinct spangle which should be required here as rigorously as with the Hamburgs or Polish.

The "Game Bantams" have had among their number some specimens of extreme beauty, especially those miniature Duckwings so deservedly the objects of general admiration at the Metropolitan Exhibition in the early part of 1853.

Reduced *fac-similes* of the black-breasted and other reds have also been successful on several occasions, and both

these promise well for supplying any gap that the failure of other hitherto more fancied breeds may possibly create.

"Mottled Black and White," and "tufted" Bantams are occasionally claimants for distinction, but rarely in such form as would encourage their owners to further efforts. Bundles of loose feathers, termed "*Tartarian or Chinese*" Bantams are only remarkable for the absence of every feature that is regarded as meritorious in this family, especially symmetrical figure and closeness of feather.

The old "*Yellow or Nankin*" Bantam has again appeared in public; and if the colours are not those that have most accorded with the general taste, well-selected specimens have had sufficient recommendation, in point of good looks, to give them additional value in the eyes of those who are partial to them from their excellence as mothers.

Partridge Bantams, again, have been shown in very good form, and in some instances, in form, as well as plumage, have partially justified their appellation, though we are decidedly adverse to that system of nomenclature which has given us these with the "*pheasant*" and the "*ostrich*" fowl of older writers, and the *Plumigen* fowl of our own time.

Our summary, therefore, of "*Bantams as recently shown*," is highly favourable to the class generally; and wherever, as in the case of the laced birds, deterioration has been evidenced, the cause seems manifest, though the remedy, so long, at least, as the breeder's object and practice continues as now, may be long sought in vain.

POLMAISE HEATING.

I BEG the use of a small space in THE COTTAGE GARDENER, to reply to Mr. Golightly, respecting that most simple and yet most economical system of heating horticultural structures with which I am acquainted—the Polmaise—which Mr. Golightly so hastily condemns, and which I so uphold as the best system with which I am acquainted.

I am at this time working old flues and hot-water as well as the Polmaise, which, if erected on a good principle, is the most economical as regards fuel and attendance over any other that ever I worked. As to the air of the house being charged with an unpleasant gas, I can assure him it is not the case with me, as it neither roasts, singes, scorches, nor blotches the most tender-leaved plants of the tropics. If he were to see how orchidaceous plants delight in this sweet, pure atmosphere, how their most delicate roots ramble and hang about, both from their baskets and blocks, he would, I think, be convinced that this is the best system of heating; and that the gardening world stands deeply indebted to the late Mr. Meek for making this most important and valuable discovery, and for publishing it to the world.

It was in the year 1816 that we erected a stove heated on the above principle, and I am perfectly satisfied with it, and prefer it to any heated by hot-water. Mr. Golightly states, that the bed or bottom-heat, and the internal atmosphere of the house, are heated simultaneously; and that we cannot heat one independent of the other. I beg to differ from him; for by closing the ventilators of the hot air chambers we stop the communication with the atmosphere of the house only; so, by gradually opening the ventilators, there is a surplus charge of sweet hot-air to be diffused through the house, which, on a cold frosty night, I find a great advantage.

As to the nursery that Mr. Golightly describes it to be for red spider, thrips, and scale, I can with confidence assure him I have none of those intruders.

In conclusion, I wish to remind Mr. Golightly that all systems are not perfect, and liable to accident. Flues may choke, boilers may burst, the joints of pipes may give way, and foul air may get in the pipes and disarrange the whole system; and all this I have found, to my mortification, on a cold, sharp, frosty morning. Again, when the water boils, how unpleasant it is to find your house full of steam, with the hot-water flying about in all directions in such frosty nights we have lately experienced.—HENRY CRADDOCK, *Kewesley, Coventry.*

HARDY BORDER PLANTS.

(Continued from page 348.)

ACONITUM ANTHORA.

THE WHOLESOME WOLFSPANE OR MONKSHOOD.

I know not for why this species should be called the Wholesome Monkshood, when, no doubt, it is as poisonous as any of the whole showy family.* This is, certainly, a choice plant, and one of the prettiest of its whole genus. It should be planted in some of the best open situations in the flower borders. It is a native of the Pyrenees, and was introduced into this country in the year 1596. It is altogether a more dwarf and smaller plant than the generality of this family. Its blossoms are showy and large, of a yellow or pale yellow colour; its leaves are finely and many cut, the segments very narrow and pointed. Its stems rise from one-and-a-half foot to two feet and-a-half in height, according to the soil and situation it is growing in. Therefore it makes a most desirable front or second row plant in the borders. It is readily increased by root division, in the spring months, when it first shows its leaves; and as our practice always is, when dressing of the flower-beds, to have a barrowful of nice earth at our heels, such as turfy-loam, and leaf-mould, or the like, from the frame ground, and when we come to a choice plant like this, we, of course, *finger* everything away round about its crown that is like a fallen leaf, weed, or slug. We then consider whether the bunch has become too large or straggling, and if so, we carefully lessen it with the fork, perhaps by inserting the fork through the centre of the bunch, leaving the best placed half to remain. Then in goes the spade to the wheelbarrow for a little fresh earth to fill up the deficiency caused by the removal of half the plant. This strengthens and keeps the main bunch up to the mark of perfection, whilst the part taken away may either be to form a bunch in some other part of the garden, or borders; or this, instead of being to form another single bunch, may be divided into many pieces. This, of course, is as required. Again, if we find a choice plant like this seems to have tired of its place or spot from long standing, we up with it altogether. This affords a good opportunity for increase by division. In this case we either change a good portion of the earth, or change its place with another plant of the same height and colour, being at the same time ever mindful to work up the soil well, adding to it a spadeful or two of fresh soil from the wheelbarrow. T. W.

SHANGHAES THE EARLIEST LAYERS.—
PRODUCE OF JERSEY COWS.

You have occasionally requested your readers to contribute the result of their experience in poultry and other matters. The following statement shows the value of a Shanghae fowl over others, for laying, at this season of the year.

In *May*, I hatched, under two hens, fourteen Shanghae pullets, and five Spanish pullets, besides nine cock Shanghae birds: and in *August*, I purchased five Speckled Dorkings of our two best dealers in London: they were extremely fine birds, and several months older than the Shanghaes. It may surprize some of your readers, but the following statement is correct.

Eggs laid by Shanghae pullets, from Nov. 12, 1853,
to Jan. 23, 1854 321!
Ditto by Dorkings 11!!
Ditto by Spanish 2!!

The Spanish laid for the first time yesterday, (Jan. 22nd;) and the Dorkings on Dec. 20. Eggs have been selling in our neighbourhood at eight for a stalling: to a large family, like mine, the Shanghaes have, therefore, been very valuable. I ought to add, that the fowls have all been kept alike.

Perhaps it may also interest some of your readers to know the produce obtained in England from five real *Jersey Cows*, from Jan. 1, 1853, to Jan. 1, 1854. We have made of butter 127 lbs, 11 ozs., besides the milk used in a family with six little children, and that consumed during the weaning of

* It was many years since believed to be an antidote to the poisonous species, and these being called *Thora*, it was named *Anthora* or *Anthiora*. It is certainly poisonous, though not so violent in its effects as the other kinds.—ED. C. G.

two calves. We scald our milk *over gas*, on the Devonshire plan; and feed the Cows on Swedes and hay, but have never any ill flavour in the butter. We could dispose of much more butter than we make.—*SPES (a Wills Clergyman)*.

TO CORRESPONDENTS.

PLAN OF PEACH HOUSE (T).—It would not do often to engrave plans, but if you tell us your situation, and what your purpose, we will advise. The subject has frequently been referred to, and the simplest is the best. The best Peaches are generally obtained from houses where the trees take the direction of the glass, being trained fifteen or eighteen inches from it.

CONTEMPLATED GREENHOUSE (Omagh).—The sun does not shine after ten o'clock, a.m., upon your ground. We should not like to advise you, though we have no doubt you would grow such things as Camellias, Azaleas, and even Geraniums, and Heaths, if you gave them plenty of air, and all the light you could. The plants would have the advantage of refracted light, even though the sun did not shine after ten, a.m. The worst of it would be in winter, as your plants would hardly have a ray at all, but they would be no worse than most plants facing the south this season, as the hours of sunshine might soon be counted. Had we the house, up it should go, manage all disappointments in some things, but we have not proved plants in such a place for a twelvemonth, with the exception of Camellias, Fuchsias, and Azaleas, and they were set out-of-doors for a couple of months, about August. Unless you have abundance of air, Pelargoniums, &c., would get leggy.

RUSSIAN ANEMONE (A recent Subscriber).—We presume it requires no special treatment, but we are not sure which it is.

SEEDLING PANSIES (Ibid).—Wintered in a frame, should have abundance of air in favourable weather, be well hardened off, and be planted out in rich, mellow, well aired ground, about the end of March, or the beginning of April. If the weather is rather mild do it earlier, and protect after planting if it should be severe on a sudden.

ANNUALSIAN LAUGHING PIGEONS (Durham).—With regard to the Laughing Pigeons, so little kept by fanciers, the fullest account of these birds is in Mr. Eaton's work on "Pigeons," p. 71. "This Pigeon is about the size of middling Bunts, and much of the same make; and I am informed has a very bright pearl eye, almost white; as for its feather, it is red-mottled, and some tell me that they have seen blues. They are said to come from the Holy Land, near Jerusalem. When the cock plays to his hen, he has a hoarse coo, not unlike the gurgling of a bottle of water when poured out, and then makes a noise which very much imitates a soft laughter, and from thence this bird has its name." We think the gentlemen who keep the Laughing Pigeons should also keep the Trumpeter. Both birds being of the Runtish kind, and having such strange voices, and if a cross comes from these birds, who knows but their offspring might laugh and trumpet in the same bird.

JACOBIN PIGEONS (R. Stone).—You mention that you bought a pair of Jacobins, but you do not mention whether they are two cocks or two hens. I presume you bought them for cock and hen, and your complaint is that they do not match up. The probability is, that if they are two cocks or two hens they never will, although the experienced fanciers frequently witness two hens matching up, laying four eggs in the nest, relieving each other in sitting; the eggs, as a matter of course, coming to nothing, although plenty of cocks are in the loft. The same will take place with regard to the cocks—two cocks forsaking their hens, matching up, sitting, although no eggs in the pan, and relieving each other in their sitting. It ever struck me to observe if the cocks would sit at night. You must prove your Jacobins thus, putting a forward hen to each, and if they play up, then you have two cocks; on the contrary, try two cocks to the Jacobins, and if they match up, then you have two hens. If, after all, the pair should be cock and hen, place them in a pen with lath partitions between them, feed and water them out of the same utensils; feed them on small beans, and give them a good supply of hemp-seed, and when you observe the hen sweep her tail, and shew, as it is called, to the cock, and as she plays in the other pen or basket, you may put her to him, and they will soon be matched.—*J. M. E.*

WHITE BANTAMS (Julia Williams, and A White Bantam).—Both these enquiries may be answered together. The fact of the first prize in the class for White Bantams having been awarded, at the late Metropolitan Show, to a pair of rough-legged, tufted, white birds, has created some surprise, and fault has consequently been found with the judges for this decision. But it appears to us that these gentlemen would be bound by the wording of the prize-list, and that no matter whether the birds in question were booted or tufted, the fact of their colour entitled them to be shown in that class. The question of how far they merited the prize, is, however, entirely distinct. The matter in dispute proceeds entirely from the wording of the prize-list, and the usual description of birds that have appeared for competition as "White Bantams," being at variance. It has, doubtless, been generally understood that the points of excellence that would here confer a prize were widely opposed to the "booting" and "tuft" that decorated the winners on this occasion, and remedy must be sought for in the more accurate enumeration of points required in certain classes, and those of which the possession would place the candidates in a different position; strictly speaking, there was nothing in the rule, subject to which these birds were exhibited, to debar their competition, but henceforth such difficulties might be avoided, by limiting a class to clean-legged, untufted specimens, or by requiring the tufted birds to be shown in a distinct class by themselves. This, no less than many like difficulties that have occurred, proves the necessity of greater accuracy in the terms of our prize lists, as also of a more generally recognized standard of merit, by which the points of competing pens have judgment passed upon them.

MINORCA FOWLS (M. F. Tavinton).—1. The Minorca cannot be called a "distinct race" of fowls. Excellence in Spanish requires the white face; the Minorca's scarlet countenance causes it to be ranked as a degenerate

sub-variety of the first-named bird, with which they have, doubtless, had a common origin; and Spanish breeders are, moreover, but too well aware of the constant tendency, in even their best birds, to throw chickens with more or less of this objectionable feature. 2. The Minorca is commonly exhibited in the class for "fowls of any other distinct variety,"—a position they would improperly occupy if in any way possessed of Spanish blood; but if this class were "for fowls of any variety not enumerated above," this might be assigned as their best place.—*W.*

PERPETUAL ROSES (W. W.).—They are not very suitable against a house, unless you had some on tall standards, and others as dwarfs. The following twelve will suit you best:—1. *Rouquet de Flora*; 2. *Le Grenadier*; 3. *Madame Lacharme*; 4. *Purpure de Tyre*, or *Tyrion Purple*; 5. *Malmaison*, or *Souvenir de la Malmaison*; and 6. *Acadiale*. These Bourbons ought to be on tall standards, and the following hybrid perpetuals as dwarfs:—1. *Mrs. Elliott*; 2. *William Jesse*; 3. *Madame Laday*; 4. *Baron Provost*; 5. *Duchess of Sutherland*; and 6. *Earl Talbot*. Or, if the Bourbons do not suit you, take the following:—1. *Standard of Merango*; 2. *Sidonie*; 3. *Queen*; 4. *Pius the Ninth*; 5. *Jacques Lafitte*; and 6. *Auguste Mic*. All these grow very strong, and will flower from May to November.

ROSE CUTTINGS (G. P. W.).—Rose cuttings when they are pruned, and elementary essays on the first lessons, to you, and such as you, are to commence next week, and will be continued for a long time at short intervals.

DISEASED GERANIUM LEAVES (Isabel).—General debility from low temperature, want of roots, and good soil, seem to be the only fault, and that you are in the right way to get over; but you certainly potted them one month too soon, because you did not keep a brisk heat for a week or two after shaking them from the poor stuff. Pray do not blame Susan. Your "clear directions" were all Greek to her, no doubt. Give very weak draughts from the hand-basin, at every other watering, all through the spring, and milk-warm, of course; and when the sun comes out strong, shade them in the middle of the day till April, and do not give them another potting till they flower.

AGE OF EGGS FOR SITTING (S. S.).—We prefer eggs not older than a fortnight. Eggs much older have produced thrifty chickens, but it is certain, as a general rule, than the older the egg the weaker its progeny.

BROKEN BEAK (H. Lawrence).—The hook broken off the upper mandible, or jaw, of the cock's beak will never be restored. The beautiful fresh redoes in the combs of fowls, which you justly admire, is the result of good keeping. To tell what this is occupies the space of half "The Poultry Book."

COW INSURANCE (N. M. G.).—There were two Societies in London for insuring the lives of cattle, but we fear they are both extinct.

"THE BEES. A POEM."—Where can this volume, written by Dr. Evans, be obtained?

BUFF SHANGHAI EGGS (A. Z., Jersey).—Write to G. W. Johnson, Esq., Canon-street, Winchester. They are all from prize birds, and are 20s. for thirteen, including the box.

GERMAN BARM OR YEAST (J. W. M.).—Can any of our readers tell us how this is made? The mode of preserving yeast in Germany is thus detailed. Put the yeast from new beer into a clean linen bag, place this in a vessel half full of fine wood ashes, cover it three inches deep with similar ashes, and press gently. Leave it for a day or two, until the yeast has become a thick paste. Then form it into small balls, dry them in a moderate heat, and store them in bags in a dry, airy place. When yeast is required, dissolve as many of the balls as may be sufficient in a little warm beer.

EXCHANGE OF POULTRY (W. H. Lockyer).—It must be put in as an advertisement.

HARTLEY'S PLATE GLASS (W. D.).—This might be employed for a greenhouse without over-lapping. It might be fitted together like plate glass, and all wet excluded, if the edges were done over with liquid putty before being joined together. Coloured illustrations are impossible for us.

FOWLS EATING EACH OTHER'S FEATHERS (John Chinaman).—If you supply your fowls with a little animal food daily, and powdered oyster-shells, they will, probably, leave off their cannibalism.

CONCRETE WALKS (A Constant Reader).—Full directions are given in previous volumes, as you will find in the indexes. We never saw the rockwork at the Coliseum.

GOOSEBERRY AND CURRANT-TREES (Suburban).—By all means give them a bed to themselves. If grown among vegetables, or round the main quarters, their roots are continually being injured by the spade. The soil is too rich, too deep, and, probably, too moist, for your fruit-trees. Take up the young ones, and plant on stations on the surface, as so often described by Mr. Errington.

SILVER POLAND FOWLS (A Pale).—Write to those who you see have taken prizes, and ask them if they can supply your wants.

WORMS IN DOGS (E. W.).—Mr. Yonatt says, that glass finely powdered is almost an unfailing remedy. Make the powdered glass into a ball with lard and a little ginger powder.

RABBITS MARKING TREES (A Subscriber).—To prevent this paint the stems with cold coal tar as high as the vermin can reach. See, also, what Mr. Appleby says to-day.

NAMES OF PLANTS (A Subscriber).—Your Fern is *Pteris serrulata*, and requires a stove. (*W. Place*).—Your seeds are of *Staphylea pinnata*, or Common Bladder Nut.

RENDLE'S PRICE CURRENT (F).—You can have one on application to Mr. Rendle, Nurseryman, Plymouth. It is very well got up.

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kalendar; and Published by WILLIAM SOMERVILLE ORR, of Church Hill, Walthamstow, in the County of Essex, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—February 9th, 1854.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 46° and 32.6° respectively. The greatest heat, 57°, occurred on the 17th in 1847; and the lowest cold, 15°, on the 16th in 1827. During the period 108 days were fine, and on 81 rain fell.

NEW PLANTS.

BRAVOA GEMINIFLORA (*Twin-flowered Bravoa*).

THIS pretty little bulb is a native of the vicinity of the Real del Monte mines, and of the mountains near Valladolid, and Miciclaan, in Mexico. Its flowers are in pairs at the upper part of the flower-stem, and thence its specific name. They are scarlet outside and yellow within. It blossoms in July, if kept in a greenhouse where the winter temperature ranges between 45° and 55°, and the summer temperature between 60° and 80°. Mr. Beaton gives some

particulars concerning it at page 241 of our ninth volume.—(*Botanical Magazine*, t. 4741.) It belongs to the Natural Order *Amaryllids*, and to *Hexandria Monogynia* of Linnæus.

BEGONIA BISERRATA (*Doubly-saw-toothed Begonia*).

Like other *Begonias* it requires to be frequently renewed by cuttings.—(*Botanical Magazine*, t. 4746.) The following we extract from the *Journal of the Horticultural Society*, ii. 313:—

“Received from G. U. Skinner, Esq., in April, 1847, and said to be from Guatemala.

“A herbaceous plant, two feet or more in height, covered all over with a short harsh pubescence. The root is fibrous, and disposed to produce suckers from its crown. The stem is cylindrical and dull purple. The leaves are palmate, doubly serrate, so oblique that there are frequently but four lobes instead of five, with the base triangular and not bordered by parenchyma. The flowers, which are pale pink, grow on stalks rather longer than the leaf-stalks, three or more in a cluster, in the upper axils or at the end of the branches. The males have two roundish, ovate, hairy, doubly serrate sepals, and a pair of very small, smooth, wedge-shaped petals, toothed only at the point.

“It is a stove herbaceous species, which grows freely in a mixture of loam, sandy peat, and leaf-mould, in equal proportions. When done growing, it should have two or three months' rest by withholding moisture from the roots. It is easily increased by cuttings, and may be flowered at any season of the year, by altering the time of starting and resting.

“A very distinct plant, but not so ornamental as many of the other kinds.”

CAMPANULA VIDALII (*Vidal's Bell-flower*).

This hardy herbaceous plant was discovered on an insulated rock between Santa Cruz and Porta Delgada, on the east coast of Flores, one of the Azore Islands, by Capt. Vidal, R.N. It grows to the height of about two feet; stem branchy; the entire plant is glossy, but clammy. The flowers are white, and partake both of the bell and urn form. It blooms in August.—(*Botanical Magazine*, t. 4748.)

PLUMIERIA JAMESONI (*Jameson's Plumieria*).

This is a handsome stove plant, sent by Professor Jameson from the neighbourhood of Guayaquil, in Peru. It is about four feet high, and blooms in our stoves in July. “Its great beauty consists in the fine red of the flower-stalks, and of the outside of the flower, and the rich yellow of the inner side of the corolla.” It belongs to the Natural Order of *Dogbanes*, and to *Pentandria Digynia* of Linnæus.—(*Botanical Magazine*, t. 4751.)

A LETTER from the neighbourhood of Leicester is now before us containing this passage—“My employer is very anxious, for the sake of immediate effect, to have nearly four hundred large evergreens, chiefly Coniferous, planted during next month, and he insists that the early spring is the best time for so doing. I wish the operation to be deferred until early autumn, and at

length he has consented to refer the inquiry to THE COTTAGE GARDENER.”

Now, we have no hesitation in replying that the gardener is right and his master wrong, if by “large evergreens,” specimens of the Fir tribe and others are intended which have attained the height of eight feet or more. Small evergreens from a nursery, which are

transplanted at such establishments almost annually for the sake of confining their roots within a small compact compass, that may be moved with little injury whenever wanted, why they may be planted by the purchaser either in autumn, winter, or spring; but such large evergreens as we have referred to should have their roots cut round *now*, and then be left where growing, prepared for removal early next October. It is quite true that large evergreens, such as we have specified, *may* succeed when transplanted in spring, but it is always at a great sacrifice, and we know an instance, last year, where every precaution in staking, mulching, and watering, were adopted relative to such trees moved the last week in February, yet one-fifth nearly of the trees were sacrificed. Large deciduous trees, ten feet high, Birch, Sycamores, Poplars, Thorns, Cratæguses, &c., bore the transplanting without a single failure.

Mr. Beaton, writing to us upon the subject, says:—"They knew as much about transplanting evergreens in the days of London and Wise as we do now; but how the change came about for planting them only in April and May, as was long the fashion, it is not so easy to say. About thirty years since, in one of the largest nurseries in the north, they would 'draw' deciduous plants until the first Tuesday in April, but none after that for love or money, as it was not 'lucky' to do so. After that day evergreens would be 'drawn' as long as orders came in; and very likely it was for the convenience of the nurserymen that the planting of evergreens was put off till late in the spring, they being the chief guides to planters, from the first edition of 'Miller's Dictionary' till Loudon brought out the 'Encyclopædia of Gardening' in 1822. Mr. Glendinning, in the 'Journal of the Horticultural Society,' made the first move towards the old style of planting evergreens early in the autumn, and in THE COTTAGE GARDENER I pushed the subject as far as London and Wise did—neither of us being aware that we only renewed an ancient practice."

The contribution of Mr. Glendinning, thus referred to, appeared in 1849, and from it we borrow this extract:—

"It would be traversing over a beaten track to enter into any general detail respecting the ascent and descent of the fluids in plants, and the formation and deposition annually of new wood in all ligneous vegetation. It will be sufficient for my purpose to state that this extension and formation takes place chiefly after Midsummer, and principally in evergreens during autumn, when the young shoots begin to attain a certain degree of consistency. It is during this downward tendency of the fluids, and when the solar action is in some measure on the decline, that I should seize and conduct with all rapidity the operations of transplanting; and, if this is intended to be conducted extensively, I should recommend the end of August as a good time to begin, September being the *safest* month in the year; selecting such plants to commence with as have matured their shoots. Another and very important reason remains to be stated why autumn is to be preferred for undertakings of this kind in preference to winter. The force of the sun during summer, although now on the decline, has warmed the earth to a considerable degree and depth, so that the mutilated roots are comparatively situated on a gentle bottom-heat, which rapidly promotes cicatrization, and frequently aids the emission of young spongelets during the current autumn.

"That the season which I have here ventured to urge for the performance of the work under consideration is undeniably theoretically the right period appears beyond all question; and being no mean experimentalist in rural embellishment, with plants of considerable magnitude, I can attest also that it is practically the season to be preferred beyond all others. I had occasion to superintend the removal of upwards of two thousand trees and shrubs, all evergreen, and varying in size from six to forty feet high, during one autumn. The trees were prepared as formerly described the previous spring, and as the undertaking was rather gigantic, the work was begun in August and finished with the year. The result was of course watched with some interest, and the following summer, when an examination took place, I found that those trees which were transplanted early in the season indicated little change from their removal, but the contrary was the case with those which had undergone similar transplantation during December. In fact the gradual diminution of the motion of the sap, accompanied with declining atmospheric action, which tended, in conjunction with the usual autumnal precipitations, to cool and saturate the earth, clearly and progressively exhibited our comparative success."

Knowing that the account-books of the celebrated London and Wise, of the Brompton Nursery, were in the possession of Mr. Hogg, we applied to him for some extracts from them that might confirm or refute the statement that early autumn was the season for transplanting evergreens preferred by those eminent nurserymen. He has furnished us with such extracts most obligingly accompanied by this comment:—"I now enclose you the extracts. There seems a fair distribution of all kinds of evergreens over the autumn, winter, and spring; but it is very evident that the greater portion were transplanted early in autumn. *For ten that are sold in winter and spring there are one hundred in September and October.* Of course you will understand I have not sent you every entry, but only such as will show that during every month evergreens of *all kinds* were transplanted."

WE now come to the consideration of those PEAS which may be called second early; the difference between the time at which they are ready for use, and those we have already described, being at least from eight to nine days, forming a very important consideration with the gardener. Till within the last twelve or fourteen years they were always sown for the earliest crops, and were, in consequence, called *Frames*, but as they some seventy or eighty years ago displaced the *Charlton* as the earliest, they in their turn have been displaced by those which have been treated of in the beginning of this monograph. As garden varieties, it is very probable they will, in course of time, share the same fate as the *Charlton*, after the improved early varieties have become more generally cultivated; and in all likelihood *Early Frames* will come to signify any good early white Pea, without any particular care having been taken in preserving the purity of the stock. For the present, however, such is not the case, for being a staple article in the seed trade much expense is bestowed in selecting them.

SINGLE-BLOSSOMED FRAME.

SYNONYMES.—*Single Frame, Russell's Early, Earliest Early, Early Dwarf Frame*, and by some *Early Kent*, but erroneously.

The distinction between a single and double blossomed Pea is not generally known. We have frequently met with those who regard them in the same sense as they would a single and double Dahlia, whereas the difference consists merely in the *Single-blossomed Pea* bearing *one*, and the *Double-blossomed*, having *two* flowers on a peduncle, or, as we generally say in our descriptions, "pods single or in pairs." There is a great disposition in all the *Single-blossomed Peas* to assume the character of *Double-blossomed*, and hence the care required in selecting them. On this account it is difficult to meet with the true *Single-blossomed Frame*, and after all it becomes a question, even when obtained, whether it is worth while to incur so much trouble and expense for any advantage that may be derived from having it of the true *Single-blossomed* character.

In the neighbourhood of Higham, in Kent, where the earliest Peas that come to the London markets are produced, I know some growers who take no small amount of pains, not only to preserve the character of

this variety, but to secure the possession of it exclusively to themselves. They save their own seed, and carefully exclude all plants which exhibit double blossoms; but it is to be borne in mind that the soil of this district is peculiarly adapted for producing early crops of every description, and there is no doubt that the Peas grown and saved on such soil, year after year, have assumed a character which they would not retain if produced under different circumstances.

The description of the *Single-blossomed Frame* being in all respects the same as that of the *Double-blossomed*, with the exception of the pods being single instead of in pairs, it will not be necessary to enter further on this subject, but merely refer our readers to that variety.

EARLY WARWICK.

SYNONYMES.—*Racehorse, Essex Champion*.

When the *Early Warwick* was first introduced, some years ago, it was a single-blossomed Pea, and somewhat earlier than the *Double-blossomed Frame* of these days. It was first obtained at Evesham, in Warwickshire, hence its name, and was, in fact, a pure stock of the true *Single-blossomed Frame*. The *Early Warwick*, judging from what is now cultivated under that name, has changed its original character, and assumed that of the *Double-blossomed Frame*. The *Double-blossomed Frame*, on the other hand, having been much improved of late years by a careful selection, has been obtained of an earlier character than formerly, and the result is, that by the degeneration of the one, and the improvement of the other, little difference, if any, exists between it and the *Early Warwick*. Still, however, they are, as I think, needlessly cultivated as distinct varieties.

The *Essex Champion*, which has been introduced within the last two or three years, and is admitted to be a well-selected stock of *Early Warwick*, though a good bearer, and an excellent Pea for large culture, does not differ from any other pure stock of the *Double-blossomed Frames*.

The sample of *Early Warwicks* which I grew were sown on the 5th of April, bloomed on the 11th of June, and were fully peddled on the 8th of July, being eight days later than *Sangster's Number One*, and *Warner's Emperor*, and six days later than *Beck's Gem*.

DOUBLE-BLOSSOMED FRAME.

SYNONYMES.—*Early Frame, Early Nimble, Nimble Tailors, Taylor's Nimble, Nimble Peas*.

I have not thought it worth while to enumerate all the names by which this variety has been known since the time of its introduction, some seventy or eighty years ago. Such a list is of no use now, as there is no instance in the present day of any one of them being employed. Those I have recorded are still in general use; but in addition to these, there are numerous others which are adopted by seedsmen, intended to convey the idea of superiority of the stock they have for sale. This is a distinction which is perfectly legitimate, particularly in those instances where the seedsman appends his name as a guarantee for the purity and excellency of the stock; and in proportion as confidence can be

placed in the house so distinguishing them, in the same proportion are the stocks likely to be genuine, for we cannot suppose any respectable house associating its name with an article which would tend, in the least, to injure its respectability, or shake that confidence which it is ever endeavouring to secure. It may be laid down, therefore, as a general rule, that A.'s *Double-blossomed Frame*, and B.'s *Double-blossomed Frame*, are such as the vendors know to have been produced from carefully-selected stocks; but as regards any difference between the two, in all probability there is none.

The *Double-blossomed Frame* produces a simple stem from three to four feet high, of a slender habit of growth, but considerably more vigorous than that of *Number One*, or *Emperor*. Pods single and in pairs, in about equal proportion, three inches long, and about five-eighths wide, perfectly straight, and terminating abruptly at the point; when full grown they become very thick, and almost quadrangular, and contain, on an average, about seven peas in each. The ripe

seed is round, and of a pearly-white colour.

It was sown on the 5th of April, bloomed on the 11th of June, and was ready to be gathered on the 8th of July.

I have seen samples of the *Double-blossomed Frame* so carefully selected as to produce, with very few exceptions, the pods always in pairs, but the expense incurred in securing this character would not be compensated by any advantage that could be derived from the preservation of it. R. H.

(To be continued.)

VEGETABLE CROPPING.—PRESERVATION.

At length a new year calls into being the most active thoughts amongst the gardening fraternity, and every man's wits and energies will, doubtless, be sharpened by the extreme and perilous season which has just turned its back upon us. Indeed, as is well known, these vicissitudes, and sudden surprises to which the more northern nations of Europe have ever been liable, have, in truth, formed, in great part, their national character, and placed them in positions of superior strength to most of the kingdoms of warmer climes. With the gardener, a fine climate begets a sort of security which is ill adapted to meet unlooked-for contingencies, and hence we hear so much about the greater amount of success in the culture of hardy fruits, &c., in situations where the inference beforehand would have been fairly against such results. Your northern gardener is a jealous creature; he has little faith in weather, and is not in the habit of poetising over zephyrs, gentle showers, the beautiful hoar frost on the window-panes, &c.,—he is a stern sort of fellow, and can scarcely afford to crack a joke.

It may here be urged, what has this to do with the heading of this paper? The answer is—Much; for it will be found that gardeners, whose lot is cast in inauspicious climes, or who have soil of a peculiarly sterile or obstinate character to deal with, are compelled to expend extra care amongst the vegetables, even as with the fruits.

I may here point to the great importance of attending to those principles as to the early winter frosts, on which the safety of tender vegetables depend: and in so doing, I will just quote my own practice, as that is close to my elbow, and has been what I should call eminently successful. With a thermometer little wide of zero, and an unusual demand for the products of the kitchen-garden, it may be surely fancied by even those who have never been subjected to such an ordeal, that the gardener's mind must be liable to much anxiety.

Well, as I before said, we northerns never trust weather; for my part, during the last half-score years of my time, I have always so laid my plans in the beginning of December as though I expected a Lapland winter; that is to say, as far as labour would carry it. This may seem pushing things to extremes by many, and, indeed, it is; but I find it a most wholesome jealousy, and one that is satisfactory in its results.

Sometimes, to be sure, a wiseacre may stare at you and say, "You made too much fuss by half, for I did not take half your trouble." But these trusting men are in a mess when the day of battle arrives, and then, forsooth, most of them will turn round and prate about the propriety of a "stitch-in-time."

But, to state details, let us take the *Broccoli Family*. Every plant we have, and I have a great breadth, have had their crowns tucked full of straw ever since the middle of December, and they now look almost as fresh as though we had passed a mild winter; the straw still remaining on them (January 24). *Bath Coss* and *Hammersmith Lettuces* were all covered up when firmly frozen in the Christmas week; they remained in this state until almost the 19th of January; that is to say, they remained covered three days after the thaw arrived; and they are in fine order, with scarcely any perceptible injury. The weather was dull when they were uncovered; and had the sun broken out, I could have restored half the covering as shade; indeed, it is always the best practice not to thoroughly uncover after long covering; we always do it in what might be thought a slovenly way, and leave a flickering screen on still, perhaps, for two or three weeks. *Coleworts*, of which, in one point or other, we have had, I should say, a quarter of an acre, were all covered thinly just as the lettuces, and, indeed, treated the same. We have had small loss, considering the style of weather we have endured. Our *Coleworts* now lie, as the *Lettuces*, three-parts uncovered; a flickering of loose, strawy litter lies over them like network.

Savoys, too, are a somewhat tender green; at least, they are not safe in such frosts as we lately experienced, especially if they are ripe in head in the autumn. My practice is to cut all the more forward with solid heads, and to stick them, with their stalks pointed close together, on the north side of a wall, or any colder spot still, if possible. Here they lie close together, and when firmly frozen, I cover them well up with litter, finishing the top in a thatching sort of style, to throw off the wet; and, if snow fall, it is not suffered to thaw on them. In fact, we treat the mass as though it were a miniature ice house, and here they keep fresh as a daisy for many weeks. *Savoy Coleworts* are more dainty. We grow a good many of the new, little, neat, green-curler for this purpose, and we have now a beautiful stock of them, as smart, as neat, and green as little bushes of green-curler dwarf *Endive* in September. These being in a green state, and devoid of hearts of any bulk, require a

difference in the mode of protection; in fact, they are managed as ordinary Coleworts.

Now, after such report, into which I have been almost imperatively led by the bearing such remarks may have on the vegetable question in winters to come, let me advert to a few features in vegetable culture peculiar to the season, for I must soon back to the Fruits again.

And, first of all, about a *rotation scheme* adapted to the succeeding spring, summer, autumn, and winter. This, in a garden of any consequence, is something more than a mere whim or fancy. It unfortunately happens, that science has done but little for us as yet in this respect; the best light by which we are guided at present being that of sound experience, which, however empirical, when taken without reference to principles, is of much value. It must be borne in mind, too, that the man of experience, or practice, is not the same dogmatical animal that would have been his character half a century ago. The public will not receive this kind of pompous ignorance, although backed by grey hairs and a stiff demeanour. The deductions, or inferences, therefore, of men of experience and good standing, in any profession, in these times, carry, necessarily, much weight, and this is just as it should be.

In advertising to rotation schemes, I have before offered my views, and I may be allowed to repeat some of them, as bearing on cultivation matters in hard-worked vegetable gardens, for such, I doubt, constitute the majority. The first great feature that has ever met my view, in a consideration of the rotation question, is the frequent recurrence, and the immense breadth of land required, for what are termed Cabbageworts, a term, the modern acceptance of which includes everything from a Ragged Jack up to a first-rate cockney Cauliflower.

It does appear to me, that in spite of all that chemistry might do for the rotation question, here would at all times be a point of such over-bearing influence as to throw many impediments in the way of the most scientific procedures. I would here, once more, draw attention to deep digging or trenching, that is to say, if you can get labour enough, for not every one who can preach such doctrines can carry them out, and if, any one should honour me with a call, and not see so much of this deep digging going on as he would be led to expect, I shall be tempted to use the language which I have, years ago, heard imputed to some irreverend lecturer, who, when accused of the difference between the precepts he gave out and his own example, replied—"You must follow the light, not the lanthorn."

When I urge trenching, however, I am not supposing it either expedient or possible for every one who possesses an old kitchen-garden to deep dig every pole of land annually. I name it for the sake of directing attention to a class of vegetables, &c., for which I have been in the habit of using the term "PREPARERS." Of such are the following:—Asparagus, Celery, Rhubarb, Leeks, Winter Spinach, Sea-kale, Horseradish, Raspberries, Strawberries, &c.

Now, these are not all preparers in the same sense precisely, some accomplish this by merely deepening the soil, others by the long period during which the plot is occupied by them, and most by the extra manuring, &c., requisite when the crop is "laid down."

I do think that all modern rotation schemers will do well to look this view of the question full in the face, and if their Sea-kale has, hitherto, been produced under blanching-pots, their Celery grown simply by the old and pitiful single row system, their Asparagus left *merely existing*, for several years, their Raspberries in a similar position, to reconsider the matter, and see whether a different mode of culture leading to better rotations may not more conduce to the end in view. I

have so often adverted to this part of the question, and in these pages, too, that some may, doubtless, grow tired of it; but I may just remind such, that the backwardness of vegetable culture and hardy fruits has been urged in the most pointed way, during the last year or two, by parties of such weight, as that their remarks may, by no means, be sighted. R. ERRINGTON.

CUTTINGS.

ACCORDING to a good authority, who has been resting awhile, at Bath, from the toils and scenes of a busy country life, "this is a season when such operations (making cuttings) interest all connected with in-door and out-door gardening." Now, it is quite true that spring is the best time to make cuttings for in-door propagation, and no one can begin too early in the spring with soft-wooded cuttings if the means are at hand; but the spring is, certainly, not the best time to make cuttings for outside propagation; nevertheless, we are all of us but too glad to receive such hints as will enable us to make THE COTTAGE GARDENER more useful, and "augment the sale of it;" therefore this is the first of "a series of articles on *Striking Cuttings*, first, of all soft-wooded plants, as Geraniums; and, secondly, all hard-wooded plants, as Roses, &c.;" on the recommendation of J. S. M. while residing at Bath.

In my busy days, I received more useful hints on gardening from Bath, than from all England, Ireland, and Scotland put together. When people go to Brighton they seem to forget gardening altogether; but when they go to Bath, it often seemed to me that it was on purpose to tell of all the very secrets of gardening to one another; and by way of proving how far any one was up to the mark, to get things sent from home to Bath to tell the tale. Poultry shows are nothing to the private exhibitions at Bath, at the end of the winter, to my own knowledge; the worst of it was, and perhaps is now, that the exhibition is not always a private one; your last cucumber to Bath may have been presented to a second party, and to gratify the presentee, it is now ticketed for all Bath to see, as from your garden in the happy land, if not from the cradle of the very science, bearing on its length and juiciness. At all events, Editors must know every thing, else they would never send me this letter from Bath, to remind me of reminiscences of "Auld Lang Syne."

The top part of a shoot is the best part for a cutting in all plants, and more so in all the soft-wooded plants; the top of a young weak side-shoot is better for a cutting than the top of the strongest shoot, for this reason, that it is not so liable to damp at the bottom as a large succulent shoot would be; but if you can get it to strike roots, the strongest makes the best plant of the two. Then, on the principle of never venture, never win, most gardeners make cuttings in the spring of as many tops as they can put their hands on; but writers do not advise young beginners to be so bold—rather to feel their way by taking the more sure and easy tops for their first cuttings. But I shall mention a great many plants by name, and say under each of them how the thing is to be done, and in different ways.

Long cuttings are not so easy to manage as short ones, and they are more extravagant; the reason is this, the long ones will not hold up their heads nearly so well as short ones, and when the head of a cutting droops it is a bad sign, and if it is not able to prick up its ears and stand erect after two days, it is a worse sign, and, instead of "being all up with it," the chances are that it will not root at all, but damp off at last. I shall tell of a remedy for such a case by-and-by. Secondly, the extravagance of making long cuttings will never be more felt than when you have only one

plant of a *Verbena*, or *Anagallis*, or of any other kind of which you expect a good many plants at turning-out time; or if that one plant has only a single shoot, and you take the first cutting of it too long, what remains will be too short for your purpose to get mere cuttings from during the cutting season.

All cuttings, except those with heels, ought to be made exactly in the same way, so that if you understand how to make a *Verbena* cutting, and also why it is that you made it just that way and not any other way, you understand how and why every other cutting in the country is made. Now, on the supposition that you never made or saw a cutting made in your life time, and considering the hard winter which made stock plants for getting cuttings from scarce, let me advise you not to try experiments on your own stock until you have learned to make a cutting as smart as any of them from the following directions:—You can learn the process by practising on any thing you can gather from the hedges, road-side, or any where—a handful of the tops of Privets, Lilacs, particularly Persian Lilacs, which are quite small at the tops—Apple, Pear, Peach, Plum, Cherry, or what not, will learn you equally as well, if you gather a lot of the tops, and try them as I shall point out. The dullest boy I ever had from the farm, or from the school, I could teach in ten minutes to make cuttings of most things, and surely it will not be any difficulty to one like you to learn all about them at once; still, a little practice on the wild things will not be amiss, seeing that *first-cuttings* will be very scarce this spring.

I never like to see a cutting of any soft plant more than two inches long, except *Geranium* cuttings, and a few others; *Verbenas*, *Petunias*, *Calceolarias*, *Lobelias*, *American Groundsel*, *Anagallis*, and *Fuchsias*, I like to be only of that length for hothed and spring work—anything shorter will do equally well, even half-inch cuttings, when one can manage them, will be better in the long run than any thing beyond two inches. I put a great deal of stress on the particular length I wish for cuttings; and I am too old now, and have been so accustomed to cuttings of all sizes, that if all the gardeners and writers in the country were to rise up against me, and say I was daft on that point, I would not give it up for the whole lot of them. The *Verbenas* grow with two leaves at every joint, one on each side of the shoot, and *Petunias* seldom grow that way, but on the *flowering wood*; this is another point on which I am just as firm as on the length of cuttings.

In the spring, we often meet with store pots of *Petunias* that were struck last autumn, and on every plant in the pot the leaves are zig-zag instead of being in pairs—at least, the top part is not in pairs of leaves, not one of which is worth a pin, they are even worse than useless, they will deceive you next May, as sure as fate, if you strike them now; the tops are “flowering-wood,” and you cannot alter their nature. One should never make a cutting from the flowering-wood of a *Petunia* in the spring; we are often obliged to make them of flowering-wood in the autumn, because most parts are then in bloom. When one makes his *Petunia* plants from the flowering-wood in the spring, the bottom part will not swell out like the new top, which it will make; the plant gets top-heavy, and unless it is fastened down at planting-out time it snaps off, or it is so twisted about with the wind that it cannot grow; and when it is fastened down, the hard, wiry bottom cannot pass up sufficient nourishment for the healthy new top, and there it remains ever so long, and you cannot tell whether it will live or die—all this time the bed might be covered. I have known very good gardeners deceived by these *Petunias*, without being at all aware of what was the matter with them; and I appeal to any of my readers who have been in the habit of planting out *Petunias*, if they have not, some time or other, met with more dis-

appointment with them than with any other plants, if ever they stood still after planting. I have been so myself, and found some of such plants to go off for two months after planting time without knowing why, and I was a long time before I found out the reason, but after finding out the cause of their going off, I made a practice of cutting back all my store pots of them in January, so that the propagators could not err in making cuttings from the wrong parts; after that, I seldom failed in having the *Petunia*-beds as full and as early ready as any beds in the garden. Therefore, before we set about learning to make cuttings, just look over your store pots of *Petunias*, and if the leaves are alternate on the top of the shoots, cut them all down to the old leaves which were on the cuttings last autumn, and put the pots into heat, they will then make new wood for the very best kind of cuttings, and be quite time enough. Although there is not another plant that does so bad from flower-wood as the *Petunia*, there are many that will be backward in starting next May, when planted out, if the cuttings are made now from the old wood or pots that stood stock still all the season; to get over this, many gardeners put the store pots into heat in January, so as to force a little growth to get the first cuttings from.

Altogether, I think the best way will be to say that the first crop of cuttings from all your soft-wooded plants ought to be from growth made since the end of last November. Those who do not want immense numbers seldom begin before the end of February, when there is no lack of this young growth, but for those who must begin with the new year, there is nothing for it but to force on purpose.

The best crop of *Verbenas* I ever had, was once when the fly took to all my stock of them, in a cold house, at the end of November, and as nothing else in that house was flyed, I ordered the whole lot of *Verbena* store pots to be removed to a house where we were forcing *Roses*, and all kinds of plants for the conservatory, and where a moist heat of between fifty and sixty degrees was kept, with good airing. I forget, now, if it was from the weather getting very cold, or what, but the *Verbenas* stood in the forcing-house, up on a shelf close to the glass, till Christmas, and every one of them made a growth in the time fit to make cuttings; the cuttings were made, and two more crops of healthy, strong growth were got before the old pots were removed. All our *Verbena* plants for that season were rooted before the end of February, and all the old store pots were thrown away. Once more; if store cuttings of *Verbenas*, or of almost any soft-wooded plant, are badly injured by the fly, and look black or smutty, no cutting should ever be taken from such parts, the tops must either be cut off or forced to new growth before cuttings are fit to be made from them.

The way to make a cutting is this—you first of all cut off the top of a shoot, say of a *Verbena* shoot, as being one of the easiest, measure with your eye down to the pair of leaves that will come the nearest to two inches, and cut it just above the next joint lower down, the bare piece from between the two joints will serve you to hold between the forefinger and thumb of the left hand, while you cut off the two opposite leaves with a very sharp knife; cut the leaves, or rather the leaf-stalks, quite close to the stem of the cutting, but do not injure the buds which nestle there; now take the top of the cutting between the forefinger and the middle finger, and put the joint from which you have just cut the leaves on the thumb-nail, and cut right across, just below the joint, with a clean cut, and the cutting is made; if the knife is blunt, or if you put much stress on it, you will make a bruised cut, or if you cut with a pair of common scissors it will be the same, and a bruised cut on so soft a part is sure to rot and fester as

soon as it is planted, and water or moisture gets to it, but a clean cut will stand safe long enough for the cutting to make roots, as the stem of a flower would in a glass of water.

Many kinds of cuttings would suck up more water than was needed if they were cut off half-way between two joints, and would run the risk of being killed by too much water so taken up, and that is the reason why they cut so close to a joint or a single leaf, because the stem is harder there than between joints or leaves, and will not take in so much water in consequence. For a *Verbeuz*, however, it is not at all necessary to cut close to a joint, for the joints of them are of the nature of Strawberry-runners, the one will root as well as the other at the joints, if they touch the ground; sooner, perhaps, than if the joints were buried deep in it.

If I had to plant a new bed with *Strawberries* tomorrow, I would take up the young plants, and leave six inches of the runner to every one of them, and I would then plant them like Cabbage plants, with a dibber, putting down the six-inch piece in the hole till the roots came just within it; with another push from the side with the dibber, I would make the six-inch piece as firm in the ground that you could not pull it up without breaking the leaves, and yet the roots would be as loose as anything, and free to work in the bed in all directions, without any cramming and cramping, and a stranger could not see how the frost did not turn out my whole plantation, after the first hard night; yet they are all as firm as London. Now, *Verbena* cuttings, also *Lobelias*, and some *Calceolarias*, could be done exactly on the same plan, getting as much of the space between the joints, to fix in the cutting-pot, as would do to hold it firm, with the bottom joint only within the surface of the sand. By this way we always did our cuttings of very scarce sorts of *Verbenas*, or new ones bought in late in the spring, and gained one joint for every cutting we made, and that joint made two more cuttings by the next growth, which was a great help to get a good stock from a small beginning. The usual way is to take three joints for a free-growing *Verbena* cutting, or a four-joint cutting, when the joints grow close together, then, by taking only two joints and the naked piece below, to fasten as a cutting, we saved the third joint for another growth. When you come to try this way, if you look sharp you may kill two birds with one stone; make a clean, smooth cut every time, and your cutting needs no more dressing, except cutting off the two leaves next the bottom, or if you have room in the cutting-pot, you need not even cut these leaves at all.

I would not advise at all to have the soil in the cutting-pot for soft cuttings pressed hard, as some people do, and as we must all do for Heath cuttings and the like of them, for I am quite sure that this hard pressing does more harm than good. To have a free nourishing compost is much better, and easier for the tiny roots to work in. I care not what kind of soil suits a soft-wooded plant best when it is out of the propagating stage, I use only one compost for the cuttings of all of them, and I never press it hard, not more than if I was potting a *Geranium*, just two or three raps by the bottom of the pot on the board, then a thin layer of clean sand on the top to keep the cuttings clean and tidy; an eighth-of-an-inch, or even less, will do just as well as an inch deep for any soft cutting, as the sand is not for the purpose of helping the cutting to root, but to keep all clean; many thousands of such cuttings never get a morsel of sand at all, but then the pot cannot be made so full as with the sand; more water will be needed, and some of the cuttings often die or damp off on the top; but with sand covering, and a good working bottom-heat, 70° to 80° strong, and no bad smells from the bed, I would not give a fig for a

man who would lose one cutting out of five hundred in March and April.

The universal compost for soft cuttings is equal parts of peat, leaf-mould, and sand, sifted as fine as possible, with an inch of the last sittings over a good drainage; if leaf-mould is not at hand, I would rather use peat and sand in equal proportions than put any kind of loam with cuttings for fast work. I have often and often missed the leaf-mould when I had it in abundance under my nose, and I know that in the great nurseries they think it a most extravagant thing to use it at all for such common work.

A three or four-inch pot is a better pot for soft cuttings than any other size, because, without good practice, one is too apt to give too much water, and if the pot is larger, the compost will hold too much water for the safety of the cuttings; but with a small pot, well drained, and with such light compost as I used, one might water twice a day without doing the least harm. Scores of times have I watered many scores of cutting-pots three times a day, when the sun was strong in March, but very little to each pot, as it was done with the syringe, but then the machinery was perfect, and a man watching every turn and shade of the movements: bottom-heat up to 90°, top-heat seldom so low as that, and nothing to shade the sun from the glass frame, no bell-glasses in use, but no air allowed as far as it could be kept close. Five days allowed to strike *Verbenas*, *Anagalises*, *Senecios*, and a few others; and ten days for the slower ones; the heat, the sun, and the syringe were the prime agents, and if the syringe was neglected for one hour after the frame was dry enough for another turn it would make a day's difference in the rooting of the cuttings, and perhaps destroy some of them altogether; it was just like risking oneself in an express train—the greater the danger and the speed, the more exciting, and the sooner ended; but the turn of a straw, and we shudder at a distance from the scene.

When one has to raise seeds, or seedlings, and force some *Hyacinths*, or grow young *Cucumber* or *Melon* plants, or any other thing requiring a different treatment from cuttings in a two-light box or pit, if a temporary division cannot be made down below the rafter to separate the different things, it is more safe to have cuttings with some close glasses over them, bell-glasses, or squares of glass. I like squares best as giving less trouble, but things will root under a bell sooner; on the other hand, squares require double pots, and they need the inside pot, or cutting-pot to be small; and I hold it as firm as a rock, that a cutting-pot was never too small yet; then the square never wants wiping like a bell glass, only to turn it every morning, and the bottom heat is never too strong for the double pot, as there is always a little space between the two to let go the heat. Another use of the square is that it compels the hard-headed ones, the dulls and the drones, to make their cuttings short enough so as to find head-room without being obliged to put the cutting-pot inside very large ones on purpose for head-room. Add to all this, that if you must have top glasses, you must either take a square of glass and double pots, or else lose the best part of the cutting-pots by the bell-glass, the sides of the pot all round being the very best part for all cuttings, and that cannot be had if the bell is on, unless you double pot and put sand between the two for the glass to rest on; but really, for such propagation as we are now contemplating, this is too much of a good thing, just like carrying coals to Newcastle. It was necessary, however, that I should show these different ways before we decided on how the cuttings were to be planted. When the frame or bed is close, and is entirely given up to cuttings, no glasses are needed unless one likes, then the pots may be brimful, and the cuttings planted as shallow as will just hold them steady, and no more,

the pots being so small one need not mind filling the centre with cuttings, but only a row round the side, and as near to each other as they will stand without touching each other.

Here, then, is a great advantage for breaking in the youngsters; a pot brimful must be very carefully watered, else all is over; but the sand takes in enough by little and little, and they can never overdo the watering; the small pot never gets too much bottom-heat, and the roots all at the sides of the pot will run down faster than by any other way, and when the plants are ready for potting off there is no fear of breaking roots. When we have to place a cutting-pot inside one that is a little larger, the smaller the outside one is the better, if it gives head-room to the cuttings under the square of glass; and it often happens that pots do not match so near as to allow of this without having the cuttings lower in this cutting-pot than those in the last pot, but half-an-inch below the rim is the lowest I can afford for young apprentices to put in their first cuttings. I once had a man that I could never shame out of pressing the soil for these cuttings as he would for hard-wooded ones, and although he lost scores by his bad practice, he persisted, in spite of me, till one day, being out of all patience, I made him do what I never heard of before, but it answered very well indeed; it was to fill a pot with the compost, and put on a layer of the driest sand he could find, and not to press or water till after the cuttings were all planted; what with the trembling from his fright, and the trickling down of the dry sand in each hole before he could get in the cutting, it was an awkward job, but every one of the cuttings took, and from the two extremes he made a useful man after that, and he hit on a good new plan for cutting-pots and seedling-pots after that, which I followed and found useful. It was to have a little hollow in the centre for holding all water each pot needed, and from this hollow the soil all round took up enough, without any falling heavily on the cuttings.

D. BEATON.

STRIKING, AND YET COMPARATIVELY NEGLECTED, PLANTS.

AGAVE AMERICANA (American Aloe).—This, according to a popular delusion, is the wonderful centenerian, that will bloom only when a hundred years old. Many a mile has been tramped by young gardeners to see a good specimen in bloom. I have already done so, and would be tempted to repeat the pilgrimage to-morrow. A flower-stem, from twenty to thirty feet in height, and with something above fifteen thousand blooms and buds, is a sight not easily forgotten. I once paid a shilling to see a "magnificent specimen" at the Egyptian Hall, Piccadilly, but it was such a Lilliputian, that I have seen a *Yucca filamentosa* very little behind it.

This genus, along with *Clivia*, *Litsea*, and the wonderful *Fuoreroya*, &c., form a fibrous-rooted division of the group of Amaryllids. The species with which I have headed this article, and its variegated variety, as well as many other species, are met with pretty plentifully in the tropical parts of America. *Americana* is not only one of the most luxuriant, but the most yielding to circumstances, as it is found equally at home in the hot plains, and at an elevation of nine thousand feet. Hence, the plant is nearly as comfortable in the South of Europe as in the central states of America. Nay, in Devonshire, it has been found to grow and bloom in the open air without any protection. A plant at Saltcombe Bay, six inches high, in 1804, was eleven feet in height in 1820, and that year threw up a flower-stem twenty-seven feet in height.

Still, unless in very favourable positions, the plant

will not endure the open air in this country; and far less could it be cultivated, with advantage, for the uses to which it is applied in more genial latitudes; such as forming impenetrable fences or hedges; yielding strong fibre, thread, and paper, from its macerated foliage; affording soap, by evaporating the expressed juice of the thick leaves; and giving abundance of a beer-like liquor, called *pulque*, by fermenting the juice that flows freely where the inner leaves are cut out just before the flower stems appear. A strong spirit is also distilled from this pulque.

I know nothing of the amount of fibrous matter derived from this source, or whether or not it could be greatly augmented. Doubtless, there are many things, such as the foliage of the Pine-apple, from which a great amount of useful fibre could be obtained. The needle-like foliage of the Fir tribe is already being brought into useful requisition. I allude to this incidentally, having lately read that so much is a deficiency of fibre of any sort felt, that even the paper-makers are quite at their wits' ends to obtain anything that will suit their purpose, the demand, owing to the vast quantity required for the cheap literature of the day, actually treading upon, if not exceeding, the supply; so much so, that ladies are besought not to waste a rag that by possibility could be converted into paper. Only think of a young lady, for the sin of waste or carelessness in this respect, being condemned to tell *such* ecstatic thoughts to the cold moon, instead of wafting them, on smooth hotpressed, to an atmosphere genial and reciprocal!

I would merely, then, in general, recommend the culture of this Aloe for its somewhat grotesque interest and beauty. The variegated-leaved one is the most pretty, but it does not grow so strong and luxuriant. The plants will never make an impression until they become somewhat gigantic in size; then, as sentinels to the entrance of a conservatory in summer, placed in pairs by a terrace-walk, so as not to interfere with the style of architecture, in fact, in almost every possible position, they have a noble effect, and will not be very particular as to the care they require. I confess, that if I had such specimens in large tubs, I should not wish to lose them by their flowering. Did the blooming of these plants become a matter of importance, gardeners would soon find the means of doing so, by rapid growth, and then early maturation. If a plant could be bloomed in the open air in Devonshire, the inference is obvious that it could be bloomed much earlier when all the advantages of house-treatment were bestowed.

What has been stated of the localities in which the plant is found furnishes the key-note to its treatment. It is generally propagated by suckers. These, when taken off, and firmly potted in sandy loam, and a little lime-rubbish, will grow quickest if placed in bottom-heat, and furnished with as high a temperature as would suit a Pine-apple. They will grow, but more slowly, in a greenhouse. In fact, before the plants become large they will get on best in the hothouse, though that need not discourage those having only a greenhouse. In either case, when the plants come, after repeated shiftings, to fill a 12 or 16-inch pot, they will be best out-of-doors for a couple of the hottest months. By the time a tub or a box is necessary for them, some nice fibry loam should be obtained, enriched with dried nodules of cow-dung, and a fair portion of lime rubbish, and some bits of charcoal, to keep the whole in rather an open state. It will be desirable to shift them not later than the end of May, that the roots may ramify freely during the summer. It will also be necessary to keep the collar of the plant well up; as if there is much soil below the bottom of the ball it will be sure to sink. After this, the Agaves, however desirable they be out-of-doors, will be looked upon as downright intruders did they want the inside of stove or greenhouse. A

different system of management must, therefore, be adopted; but out-of-doors it will be desirable they should be, from the middle of May, or earlier, until the middle of October, if the autumn is fine. Where room in a greenhouse or orangery, &c., cannot be given, a warm shed, stable, &c., should be secured, and a small truck with wheels would assist the moving of the plants. The successful wintering, in the above supposed circumstances, will greatly depend on the soil being rather dry before housing. To secure this, means should be resorted to for throwing the autumn rains past the soil. No frost above a few degrees, better none at all, should touch the plant. In severe weather they may be covered up, top and tub, with dry hay, freed from its seeds. In a mild winter, or during mild days, if the place in which they are wintered be dark, they will relish being wheeled to the door during the heat of the day. No water will be wanted at the roots until placed in the light next spring. The leaves, if at all dirty, may have a sponge drawn along them, as the cleaner they are the better will they look and thrive. As the sun gains strength in June, the plants will want water rather liberally, and manure-water may then be given alternately with advantage, or if that is not convenient, a mulching of rich compost may be substituted. By September, little or no more water will be required, and even rains should be kept from the soil as much as possible. This will render the large leaves firm and compact, and in this state they will stand much rougher treatment during the winter.

LITTEA GEMMINIFLORA (*Syn.* *AGAVE GEMMINIFLORA*).—This is a very singular plant from Peru, which, although requiring a greenhouse when young, and delighting in a higher temperature in its infantile state, will, when old and seasoned, prove, it is expected, as hardy as the Agave. Imagine a short, knobby stem, with numberless long, rush-like foliage proceeding from it; all of these, with the exception of the younger central ones, which are upright, have a pendulous, weeping character, so as to hang gracefully over the pot or tub, and you will form a good idea of the interesting appearance of the plant, even though you should seldom see its splendid flower-stem issuing from the centre of the foliage, and rising, like a huge tapering-to-a-point beetle-brush, to a height of from twelve to thirty feet, the greenish-yellow flowers, with the stamens and pistil standing freely out beyond the petals, averaging three inches in length, and produced in succession along the sides of the stem.

The plant was named in compliment to a Milanese nobleman. It was introduced more than fifty years ago; and, so far as I am aware, bloomed first in this country at Mr. Knight's exotic nursery in 1826, the flower-stem appearing in the middle of August, and reaching fourteen feet in height by the middle of November. I think it is very likely that plants may be found in the same establishment. It had bloomed previously in the continent, and plants had been raised from its seeds. A specimen bloomed at Brussels, in 1837, the flower-stem reaching the height of thirty feet, and having from 1000 to 1500 flowers. Two years ago, a small, healthy specimen bloomed in the Botanic Garden, at Chelsea, the flower-stem, in November, reaching the height of eleven feet. It had been kept in a greenhouse for several years, receiving the usual treatment given to Aloes and plants of that character. In all the instances of its blooming, with which I am acquainted, the flower-stems have made their appearance in autumn, and reached their culminating point before mid-winter. It would seem, therefore, that the heat and the light of a summer's sun were necessary to the maturation of the plant. If, then, it was desirable to bloom this plant at an early period, a leaf must be taken out of the modern successful Pine-grower's book, and thus accomplish rapid growth

and early maturity. I can recollect huge Pine plants standing in pits, and producing fair fruit when they had received some half-a-dozen-of-years' attention. But I have seen as fine fruit on little squat plants,—such, for instance, as at Trentham,—the plants being scarcely eighteen months from the sucker. Although this plant would not need the same amount of heat as the Pine; still, a higher temperature than the greenhouse, with abundance of light and air, would hasten its period of maturity, and this latter would be still farther done by abundance of light, and reducing the water to a minimum in summer before the plant was wanted to show in the autumn. When the plant is more generally diffused, and even flower-stems from six to ten feet in height duly appreciated, there will be means taken to make it bloom early. The simplest culture will suit it. It can be raised from ripe seeds, but is generally propagated by suckers. It delights in sandy-loam a little enriched. In winter it will require little water, and in summer weak manure-waterings will be acceptable. The temperature of the greenhouse will be quite sufficient, unless when it is desirable to rattle it on when young.

FUOCROYA GIGANTEA.—Another commemorative plant, and resembling an Agave in appearance. It has been introduced 160 years, but has seldom been seen in flower. It bloomed at Waleet, in Shropshire, in 1821. It requires similar treatment to an Agave.

FUOCROYA LONGEVA is, like *Gigantea*, from South America, and a still more wonderful species. Its specific name may have reference to the slow rate at which it grows, as the natives have a belief that it flowers once in 400 years. It was found on Mount Tanga, in the province of Oaxaca, in Mexico, at the elevation of 10,000 feet; and, therefore, deemed hardy enough to stand our climate, at least, in the southern counties. Several plants were introduced in 1833; so that we may wait long until we see one of its wonderful flower-stems at home, if the tale of the natives be true. Without that splendid appendage, if found hardy, it would constitute a fine addition to rugged and rocky scenery. Its clean, upright stem would resemble an oldish plant of *Yucca aloefolia*, but the large cluster of long sedge-like leaves on the top, differing from the upright foliage of the *Yucca*, has a drooping, pendulous position. From the centre of this mass of foliage the wonderful flower-stem rises. Baron Harwinske found specimens, with clean cylindrical stems, twelve to eighteen inches in diameter, and forty feet in height, and then a flower-stem reaching another forty feet. The appearance of a graceful, finely-formed Spruce Fir of that height, forty feet, raised upon the top of a clean pole some forty feet high, with a huge coronet of drooping sedge foliage at the point of junction; only supposing that that tree was a mass, not of green leaves, but of white blossoms, would give no bad idea of this wonderful flower-stem. It would be interesting to know what progress the plants in this country have made.

YUCCA.—The whole of this genus is of easy cultivation, rejoicing in deep sandy loam, and all are hardy enough for England, with the exception, perhaps, of *aloeifolia*, which, especially when the stems get to a great height, might have a little protection in winter. The genus is as striking among Lilyworts as those already referred to are among Amaryllids. I saw *Yucca gloriosa* in bloom, in several places last season. The beautiful, low-growing *filamentosa*, that throws up a flower-stem of from five to seven feet, is always a welcome sight in any position. Taken as a whole, however, the plants of the genus, all of them interesting, make little show when grouped together; and neither do they harmonise with fine architectural or symmetrical lines. Sparingly introduced, they make a striking appearance from contrast. For instance, a huge bush of *Gloriosa* is rather a taking object on a well-kept

lawn. Wild scenery, and huge rock-works, are the scenes in which they would revel and feel most at home. When walking through such places in princely establishments, I have often thought what fine accessories the *Adam's Needles* would give. No place is so small but a few of these plants would lend it an additional charm. They are easily propagated by suckers and offsets. I think Mr. Beaton has already referred to this singular tribe, and a proper defence and recommendation of their peculiar fitness for certain circumstances could not be left in better hands.

R. FISH.

THE CYCLAMEN.

(Continued from page 362.)

THE flowers of these plants are, as I have said before, exceedingly beautiful, but I must also claim for the foliage of many of the species the same praise. The markings of the leaves are almost as beautiful as those of the leaves of some of the *Anætochilus*, which my esteemed friend, Mr. Beaton, has written about lately. Almost every seedling plant of *C. Europeanum* and *C. hederifolium* have different shades of white and green on their leaves, so that in raising seedlings the interest of the cultivator is greatly heightened thereby.

In describing the potting operation, I omitted to mention that *C. com* should have the bulbs covered about a quarter-of-an-inch. The reason for this difference I can scarcely say, but it is practised by all growers, myself included. It may be, that if the bulbs were left exposed the leaves of this species would fall down and be very irregular, instead of forming a neat, handsome plant. It is difficult, in some few cases, to give a satisfactory reason for some particular point of culture, and this is one. Experience says—cover the bulbs with the compost a quarter-of-an-inch, and I know of no reason to depart from the rule.

Summer Culture.—This season I will suppose to commence as soon as the leaves begin to push forth, which generally happens, if they are cultivated in a cold frame, about the end of January. They will then require a gentle watering; and as the leaves advance the quantity should be gradually increased. The month following the flower buds will begin to appear; then, if the possessor has a greenhouse, they should be removed into it, and placed near to the glass, to keep them from being drawn. In this position more water will be required; but the soil should not be kept constantly wet, but allowed to become dry on the surface between each successive watering. Plenty of air will be beneficial on all favourable occasions; and when the plants are fully in bloom they may be placed in such situations of the house as will show the beauty of the flowers to the greatest advantage. I have them placed upon empty pots turned upside down, which elevates them above the other plants upon the platform, or stage, where they stand.

After the bloom is over, and the late frosts all gone, I set them out-of-doors upon a bed of coal-ashes, in front of an east wall, where they can enjoy the morning sun. Water should still be given to them in dry weather, the grand object being to preserve the leaf and root-action for two or three months. This gradually increases the size of the bulbs, and stores up a large amount of vigour for the following year. By the end of June, the leaves will begin to show symptoms of ripeness and decay, then withhold water, and to ensure perfect rest, lay the pots on their sides, so that no summer rains may cause precocious growth.

During all this treatment in the open air keep a constant look-out for slugs and snails. These pests are very much pleased to feed upon the young buds, which,

if eaten off quite clean, destroys them effectually. I believe they are more destructive to these charming plants than any other, therefore be diligent in hunting them out of their hiding-places. They may generally be found lodging under the pots, and sometimes form a neat, snug homestead, or den, in the hole at the bottom of the pots, from whence, if they are not discovered and destroyed, they may issue forth at night and make sad havoc.

Winter Treatment.—The operations for the winter treatment are easy and few. I suppose this season to commence about September. They will then, or, at least, should, be completely at rest; but as frosts may then be expected it will be prudent to protect them, and as a removal to effect this must be determined upon, it will be well then to repot them at once. That operation enables us to get rid of all worms or slugs that may be in or about the pots. I need not repeat how to repot them, as I have already sufficiently described how to perform that operation under the head "Potting." When all are potted, then place them in a cold frame, on a thick bed of coal-ashes or sawdust. If the latter is used, place a thin layer of soot over the soil first,—this will effectually prevent worms from penetrating through the sawdust into the pots. In this position they will require no water, and should have the lights drawn off all fine days; even if a little frosty it will not hurt the more hardy kinds. The *C. persicum* requires a somewhat different treatment; it is a decided greenhouse plant; and when repotted, which it should be at the same time, it should be placed on the greenhouse shelf immediately;—the cold frame is too cool for it, even if well covered-up; besides, it flowers much earlier. I have a fine plant of *C. persicum rubicundum*, a splendid variety, now, at the moment I am writing, in fine flower.

During severe weather it will be advisable to cover-up even the more hardy ones with a mat or two, to break off the ill effect of long-continued severe frosts; but as soon as the leaves grow remove the plants into the greenhouse. These plants always, excepting *C. persicum* and its varieties, may be grown out-of-doors; but as my allotted space is full, I must defer their culture out-of-doors to another opportunity.

T. APPLEBY.

(To be continued.)

STOVE FERNS.

(Continued from page 206.)

DRYARIA TRIOIDES (Iris-like).—An East Indian Fern, of a rather coarse habit. Fronds simple, of a long spear-like shape, sometimes lobed at the margin. The seed-vessels are very small, and thickly placed on the upper part of the fertile frond. In this Fern occurs the rare case of having the veins in the interior of the frond. Easily increased by its creeping rhizoma. It is very suitable to grow under large Palms, or other tall-growing stove trees.

D. LONGIPES (Long-stalked).—Another East Indian Fern, with a peculiar long leaf-stalk, hence its specific name. The fronds grow three feet long, and are pinnate and leathery; the pinnae grow laterally and have segments very broad towards the base; seed-vessels large, in two rows. Increased by dividing the creeping root-stock.

D. MELANOCOCCA (Black-stemmed).—An East Indian Fern, of a tall, graceful habit. The fronds reach frequently the height of three feet, and are pinnatifid; the pinnae are distant from each other, and are rather sharp-pointed, and of a light green. The seed-vessels are large and placed in one row, rising up above the surface of the frond. It is a fine Fern, easily grown, and increased by dividing the creeping rhizoma.

D. QUERCIFOLIA (Oak-leaved).—This fine Fern has a wide geographical distribution. It is found in all the hottest parts of the East. Fronds various—one variety has no fertile fronds, at least, not cultivated in our stoves. The fronds of this variety are sterile and pinnatifid, with deeply-cut segments, approaching to the form of the oak-leaf. The real well-defined species has both sterile and fertile fronds on the same plant. The sterile fronds have no stem, are heart-shaped, and jagged, or wavy, at the edges; the fertile fronds have a short stem, are pinnate with narrow segments, each segment having a thick binding or edge. The seed-vessels are circular, and are placed in groups over the under surface of the leaves. Both are well worthy of cultivation. I have grown the species on a low shelf, far from the light, with the pots plunged in moss, into which the roots ran freely, and by this moist, steady treatment they grew very satisfactorily. I found it easy to increase by division.

D. VULGARIS (Common).—This is the *Polypodium phymatodes* of Linnaeus. It is a handsome, broad-leaved Fern, from the Malay Islands and the Mauritius. The fronds are pinnate, and grow more than a foot long; each division is almost triangular and broad. The root-stock creeps very much, is black and scaly. The seed-cases are round or oval. I once had a large plant of this fine Fern under my care, growing in a large wire basket, the creeping root-stocks grew through the meshes of the basket, and threw out, as they crept round it, their large, broad fronds. It was a noble plant, measuring full two feet diameter, and was much admired. It will, however, grow very well in a pot, or amongst rockwork in the stove. The plant alluded to would have made (I speak within bounds) at least a score of plants had it been divided. This example shows that it is easily increased by that mode.

ELAPHAGLOSSUM.—A genus formed from *Aerostichum*; distinguished from that and other allied genera by its simple fronds with forked, distinct veins.

E. CALLEFOLIUM (Calla-leaved).—A Fern from Java, that hot country, hence it requires the warmest part of the stove or orchid house. It has barren and fertile fronds, the former rather broadly acuminate, or sharp-pointed, shining deep green, with wavy edges; the stems are of dark colour underneath. The fertile fronds are narrower and more erect. Both fronds grow about a foot high, and are jointed at the base. The root-stock creeps, hence it is easily increased by division. A desirable species for any collection.

E. CRASSINERVA (Thick-nerved).—This West Indian Fern may be distinguished from the last by its stouter leaves and thicker veins, and by the height of the barren fronds. These attain, frequently, two feet in height, whilst the fertile fronds never exceed one foot. The barren fronds are also undulated, and of a dull green. Easily increased by dividing its short, creeping root-stock.

E. CONFORME (Conformed).—A species nearly hardy enough for the greenhouse, but thrives better in a cool stove, through the winter. It is from the Cape of Good Hope, where it is found growing on shady rocks. The sterile fronds are very beautifully veined with almost perfect regularity, and of a long oval form, narrow at the base, and terminating in a sharp-point; growing about a foot high. The fertile fronds are much smaller, and covered throughout with seed-vessels. The root-stock creeps, and is covered with scales. Increased by division. It is a pretty, neat species, and worthy of general cultivation.

E. DOMBEYANUM (Dombey's).—A South American Fern, remarkable for having the sterile fronds thickly covered with star-like scales. The form is blunt, line-shaped, narrowed at the base. The fertile fronds have stems nearly half the length of the frond, and are of the same shape, excepting they are more pointed. The

root-stock creeps, and therefore it may be increased by division. A very distinct and well-defined species that ought to be in every collection.

E. LONGIFOLIUM (Long-leaved).—This is the tallest species of the whole genus, growing in its native country (West Indies) fully two feet high. Sterile fronds, lance-shape, narrow at the base, and sharp at the extreme point, and rather wavy at the edges. Fertile fronds erect, and the same form, rhizoma creeping, and easily increased by division.

T. APPLEBY.

(To be continued.)

TREES ADAPTED FOR PARK SCENERY.

It is too often the case, that in spite of the efforts we make to cast off prejudice on one side we are fostering it on another. Indeed, so much so, that honest John Bull seems at all times the victim of quackery. Only very recently he was led to believe in the prophetic revelations of polished timber, when it had, by the carpenter's assistance, assumed the form and exercised the functions of a table; while only a short time before that certain lecturers assured us they exercised an almost irresistible control over the minds and persons of many of their hearers. These sciences of Table Turning and Electro Biology had, in their turns, obtained so many disciples and believers, that it afforded grave doubts with our elderly worthy dames if their marvellous disclosures had not some connection with the Prince of Darkness; unfortunately for society at large it did not appear that either art, for it is not just to call them sciences, was ever applied to any useful purpose, so that they seem likely to pass into oblivion without leaving a trace of that utility behind them which now-a-days forms a leading feature in every thing that is inquired for. However, it is not likely to be long ere another subject of novelty (it would be treason to call it quackery so soon) takes the place of the discarded ones, and John Bull will run as eagerly after it as if it were the first shadow he ever followed. Fortunately, there are sober moments, and, as it has been often remarked, the most sensible periods are those which follow in the wake of the grossest folly, we may pardon our volatile nature for now and then having a rambling fit; but these sudden departures from old and well-established rules are not the only errors we run into, others equally unpardonable are enacted every day. In our generalization system we seem to make too few exceptions, and a rule, if once laid down, and receive the stamp of society at large, is rarely withdrawn, even if it be after found to be fallacious, and those who are convinced of its being so, are not always the first to abandon the idea. Few people, now-a-days, profess to believe in the prophetic notices contained in a weather-predicting almanack, yet Francis Moore's publication is, perhaps, as much patronised as ever, and his mysterious out-pourings are annually set forth to puzzle those who take the trouble to read them, while in many other things the case is the same as in that of almanacks.

Now, though the above may not seem to have any connection with the ordinary affairs of horticulture or agriculture, yet the same spirit now and then exhibits itself in these sciences. A plan—a mode—or an idea—put forth on the authority of some aspirer after fame, is received for a time, and the thing is lauded as being a boon to society, before which the steam-engine or printing-press sink into insignificance. By-and-by, however, its demerits are found out, and it takes its place according to its worth, and not unfrequently, when it has been publicly found out of occupying a higher place than it deserved, it has received a corresponding severe degree of punishment, and been condemned with more harshness than justice. Now, in accordance with this rule,

some useful plants and fruits have been cast aside because their adopted sponsors had the imprudence to laud them to a degree they did not deserve; however, their resuscitation has often been effected through the instrumentality of their accusers carrying their malice too far, as well as from the aid of their friends' good word; still, after all that, now and then false ideas will creep in and maintain a place, as it were, backed only by the traditionary story which gave them their origin.

I should think there are no readers, from those just removed from the Primer upwards, but are aware how much the Oak has been praised as possessing all the qualities in itself which a multitude of other trees only contain amongst them. Its general features, size, form, foliage, and the manifold uses of its timber, has, with other considerations, conspired to render it the especial favourite of the poet and naturalist, while a sort of veneration seems to hang over it in the less informed class who are not readers, from the reports they have heard of the useful part it takes, or has taken, in contributing to our national greatness. This feeling, alas! threatens to become an erroneous one, since the quantity of home-grown Oak timber, now used in ship building, forms but a very small portion of what is used in that way; however, we do not attempt to deny it the place it has so deservedly attained, neither do I condemn it as lacking those points so much insisted on by its admirers, but I do condemn those who can see neither beauty nor utility in other trees, merely because they are not Oaks. Now, as all trees are not necessarily wanted for the same purpose, it follows that those of other kinds may be equally useful in their respective ways as Oaks. Carts, waggons, and buildings, are equally necessary to a comfortable existence as ships, and timber to make them must also be had somewhere, and the weight of Oak, with some other faults it has, renders it not the most prized timber for articles of a locomotive character; however, I will waive this point also, and leave the wheelwright and other village mechanics to urge their own case with the self-constituted patriot who will only plant Oaks on his domain, and confine my remarks to its merits and demerits as a park tree for giving effect to the general scenery there.

I readily grant, that if we take a general survey of many domains, or even districts, that the Oaks will be found to exercise a wonderful influence in giving these districts a character, more so than any other tree planted there; however, there are other places where others predominate, as well by their size and utility as by their numbers; and, moreover, some of them present as fine appearances, when we can divest ourselves of the poetic feeling the Oak inspires, as does the King of the Forest himself. Might I ask, how much does the *Beech* avenue lack in the shape of pictorial beauty? And even as a single tree it possesses many of the good qualities ascribed to the Oak: its foliage, in summer and autumn, presenting as many points to the landscape painter as the Oak does, and in winter its feathery boughs are no less pleasing. There are many fine *Beech* avenues attached to country mansions, and they are, possibly, as much regarded as Oaks would have been in their places. Then we have the *Elm*, which also makes a fine avenue, growing quicker than either Oaks or *Beeches*; but it is not so long-lived, only in places where the soil is suitable it gets larger than either the above, and *Elm*-trees of extraordinary size are not uncommon, while very large Oaks are not so plentiful; but I cannot say that I approve of the *Elm* avenue, and still less of its appearance as a single tree;—but it has its merits, and deserves attention.

In dry situations, in the south of England, the *Sweet Chestnut* often forms a pretty object as a park tree, and for an avenue, it is, perhaps, not exceeded by any; but its timber is not so valuable as Oak, which, in some

respects, it resembles, as it is liable to splinter when sawn up, so that timber-merchants do not like it, although, in point of durability, &c., it is fully equal to the Oak; while, for appearance, its glossy green leaves, and its no less interesting flower in August, render it very attractive, and its winter appearance is not bad. I believe it is longer-lived than the *Elm* and some other trees; but, as I say, the timber deteriorates in value just as it gets the size that is most wanted for ship-building and other purposes, and this bad property seems to be the same on all soils.

Amongst a host of other trees having expanded tops, the *Sycamore*, *Lime*, *Norway*, and *Common Maple*, have all their respective claims, and some planters insist much on the merits of the *Lime* as a park tree or one suitable for avenues. Its quick growth certainly entitles it to respect, but some of the hard-wooded kinds are certainly more appropriate in many points in view. The *Sycamore* is also a quick-growing tree, and far from being unsightly, although, in point of interest, it must succumb to the *Walnut*, which is more deserving of attention than any of the last-named; while the *Horse Chestnut* has also its admirers, and as a single tree it is excelled by none, but its uses in forming an avenue or group is somewhat questionable, and its coarse, rampant growth makes its appearance less graceful than many other trees; it, however, grows very fast, and if mixed with other trees speedily overtakes many of them.

In thus mentioning many of the common trees which give effect to our landscape, we must not forget one which is but rarely planted, and certainly deserves more attention than it receives,—the common *Wild Cherry*, which, when in flower, forms a very pretty object, and when not so, its upright growth is not at all ungraceful. It certainly looks as well as the *Poplars*, which are here and there admired, but which ought to be sparingly introduced into groups or lines in park scenery, but they are useful in the continuous belt, where the latter is indispensable, because, overtopping everything else, they break that monotonous outline the belt so often presents. However, as my present paper has far exceeded the limits I intended for it, I must cease, but send a few more remarks hereafter in continuation of this subject, relating to such trees as are less common, and venturing a few observations on the recently imported ones, more especially on the *Pinus* tribe, which some planters think will effect a revolution in our forest trees and woodland scenery; but without denying these interesting trees the merit they deserve, I cannot bring myself to the belief that they will oust our own long-tried and trust-worthy native specimens, neither do I think they will even successfully compete with them in the points on which these admirers call their "forte," for I believe our own trees combine more of the truly beautiful and useful than any of these far-fetched and costly productions so much admired by the collectors of novelties.

J. ROBSON.

THE FATTING OF SHEEP.

(Continued from page 365.)

SEVERAL distinct systems of feeding are now in use. One, whereby the sheep receive the roots cut and placed in troughs, and an allowance of hay in addition; and another, in which they receive turnips and hay, with an allowance also of oil cake, or corn, or both. Believing, as I do, that both these methods of feeding are useful under certain circumstances, I cannot recommend one in preference to the other; but will proceed to state how, and in what manner, they may be both beneficially employed.

The former method is most suitable for the richest soils, where the use of oil-cake and artificial feeding materials, in addition to the consumption of a heavy crop of roots, would be found too stimulating for the cereal crops which usually follow. The latter is an excellent method of feeding Stock upon soils which require extra manuring, and when it is desirable to fatten the animals in the least time; for I consider the system of cake-feeding, although costly, yet highly advantageous, as it may be fairly calculated that about one-half should be charged to the stock, the other to the land as manure. There is yet another mode of feeding, whereby the Sheep are allowed to eat the roots on the land uncut, and receive, at the same time, cake, or corn, and hay; but this only applies to very dry soils, where the roots can be eaten upon the land without waste; for upon all other soils there would be a loss, by waste, equivalent to the cost of cutting, independent of the disadvantage to the stock.

In making a comparison of these modes of feeding, my experience teaches me that the Sheep will fatten as fast upon soils in general, when they get the roots cut and given in troughs, with a liberal allowance of good hay, as they will when allowed to eat the roots on the land uncut, and receive, at the same time, half-a-pound of oil-cake each, with hay. When Sheep are fed upon roots, for fattening, it is necessary not only that a sufficient provision be made, but that different kinds of roots should each be consumed at the period of the year when they contain the greatest amount of nutrition, and in order to secure this advantage, I would use them in the following order, commencing with the varieties of common Turnips, which may be continued till the month of December; after which time, the Swedish Turnips will be best, and may be continued up to the month of April—indeed, when sufficient care has been exercised in their preservation, they may be used with success through the month of May. In general, however, Mangold Wurtzel will be preferred at this time, and during the summer months. White Carrots are also beginning to attract the attention of graziers; and, as they are palatable and nutritious in an early state, October is not too soon for using them, and they may be continued in feeding up to the month of March. There have been tables published, showing the comparative nutritive value of these roots, obtained from analysis by different chemists, the results of which, if not actually alike, yet serve to furnish us with useful information. They are, by analysis, classed somewhat in the following order:—Mangold Wurtzel, the most nutritious; Carrots next; then Swedish Turnips; and last, being the weakest feeding root, the common Turnips. There is, moreover, another excellent feeding plant; and, although it cannot exactly be classed with roots or bulbous plants, yet it must not be passed over in silence. I allude to Rape. I do not recollect seeing any analysis of its feeding properties, but, as it is known to be very valuable and fattening, as green food, in the early part of the season, I consider it the

best farm produce for fattening Sheep, during the months of August and September.

My own experience enables me to recommend the feeding of Sheep with artificials, as they are called, in most cases where the land requires the extra manure which will be left by their consumption. In this method of feeding, regard must be had not only to the feeding value of the materials, but also to the money value of the article in the market; for, although the sagacity of buyers and sellers generally goes far towards assimilating the two values, yet there is often an advantage to be gained when purchases are made in anticipation. There is, also, much difference, as well as peculiarity, in the nutritious and feeding value of those substances which are comprehended in the list of artificial materials. There is some considerable difference in the value of cake, as shown by the chemical analysis of Professor Way, entered in the 24th Number of the Journal of the Royal Agricultural Society of England, and which places the English cake first as the most nutritious; it, at the same time, gives the feeding value of Rape cake as equal to Linseed cake, and also shows that the value of Peas and Beans are very nearly allied for feeding purposes. There is, also, a valuable and interesting statement of a series of experiments in the 33rd number of the above-named journal, carried out by Mr. J. B. Lawes, and although it relates to Pig-feeding, it is, on the other hand, quite sufficient to exhibit the value of the materials for feeding Sheep. It is there stated that the feeding value of pulse and leguminous crops, such as Beans, Peas, Tares, Lentils, &c., is found to be greater than that of the cereal crops, such as Oats, Barley, &c. Now, although we shall do well not to entirely disregard the evidence of chemical analysis, it is, nevertheless, desirable to enquire how far these results coincide with our own practical experience of their value. I find that American Barrel-cake is superior in feeding value to any other Linseed-cake, and it carries in the market a higher price, showing, also, that it is estimated as superior by feeders in general. There is, however, nothing in the above-named analysis which justifies these conclusions.

Another instance must be noted in which experience and practical application corroborates the accuracy of the analysis, thus, Mr. Pusey finds that his Sheep do equally well upon Rape-cake as they do when fed upon the like quantity of Linseed-cake; my own use of it supports Mr. Pusey's statement as regards the feeding of Teds or Hoggets, but not so as regards the feeding of older Wether Sheep, or Ewes, and fattening Lambs, more particularly when given in admixture with Linseed-cake, for I find that the Stock will eat the Linseed-cake in preference, it being more palatable than the Rape-cake, although, probably, not more nutritious. I find, also, that Sheep sometimes eat the Rape-cake very well for awhile, but after they get into good condition, and well-advanced in fatness, that they refuse it altogether, particularly when they receive an allowance of well-made Clover Hay. One thing, however,

must not be overlooked, in case of waste, or dropping-out of the feeding troughs, it may be considered that Rape-cake is worth all its cost as manure, whereas Linseed-cake, under the like circumstances, is not worth more than two-thirds of its cost in the market. Reverting to the use of corn and grain for feeding Sheep, I must observe, that it is bad practice to use any of the leguminous crops in the fattening of Sheep, except in admixture with cake, and they are then required only for about a month, at the latter part of the fattening process of wether Sheep, or aged Ewes, for the purpose of rendering the flesh firm. They may, however, be used for fattening Lambs or Hoggets throughout, the excess of Nitrogen they contain acting favourably in the production of flesh in all young animals. I condemn the feeding of fattening Sheep with Oats, Barley, Indian Corn, Bran, &c., being both wasteful and unprofitable, as compared with oil-cake and the legumes.

The opinions here advanced are based upon my own observations, and they are strongly supported by the late experiments of Mr. Lawes. There is, however, one important point worth observation, and which Mr. Lawes has exhibited; that the residue of the legumes, after consumption, is of more value as manure than that to be obtained from the Cereals.

JOSEPH BLUNDELL.

(To be continued.)

SEA WEEDS.

(Continued from page 350.)

THERE is something very surprising in considering the spores or fructification of marine plants; so minute, that, even with the assistance of the microscope, there is as yet considerable obscurity regarding them. Specks, so small as are these spores, not visible to the naked eye, and yet each tiny atom containing *life*, and capable, under favourable circumstances, of producing plants, some of which are of large dimensions, is a fact so wonderful, that the mind is lost in the contemplation of it, and is led from the astonishing effect to the first Great Cause; to Him who in *wisdom* has made all; whose works do, indeed, praise Him. There are wonderful things lying hidden in the mighty deep! Many which are rarely seen by man, and many which are passed by, either because they are common, or the attention has not been directed to them, or from a want of knowledge of their beautiful structures. I can assure my readers, from experience, that an interest in the beautiful plants of the ocean is much to be desired. Many an hour, which would have been passed by the invalid in comparative dullness, has been cheered and made delightful by the arrival of some of these interesting objects, and sometimes even a sleepless hour in the night has had light thrown upon it by the remembrance of their wonderful beauty. And what an inducement, for those who are ordered to the sea-side, to walk out, day by day, in search of them, when, under other circumstances, they would have wandered listlessly about, and not have received half the benefit; for it is of great importance that the mind should have healthy exercise, as well as the body, so closely is the one connected with the other.

ORDER II.—RHODYMENIACEÆ.

Red or purple Sea Weeds, with a root like a disk, but sometimes branched and matted; "Frond very variable (says Harvey) in habit and colour, either leafy or filiform, or much branched; in some an intense scarlet; in some crimson; in others brown-red or purple; the substance is rather thick.

I. STENOGRAMMA.

Named from two words signifying narrow, and a line, because the fruit is in lines.

1. *S. INTERRUPTA*.—This plant, which is washed up from deep water, is very rare, though Miss Gifford has found it in tolerable abundance at Minehead, in Somerset. It is of a fine red and much lacinated; fan-shaped, and rather resembling *Rhodymenia palmata*; from three to five inches long, and about as wide.

2. RHODYMENIA.

From red, and a membrane.

1. *R. BIFIDA* (Two-cleft).—A rosy-red, transparent, thin frond, forked from the base; "the margins fringed with ciliae."

2. *R. LACINIATA* (Torne).—This beautiful weed grows

upon rocks and stones in deep water; the frond is rather cartilaginous, of a bright red, fan-shaped, flat, and much divided in a wedge-like manner. The margin, when the plant is in fruit, fringed with "ciliary processes, in which the tubercles are placed, or with tetraspores forming cloudy spots along the margin." I found this weed in great abundance and remarkably fine at Spittal, near Berwick-upon-Tweed. It is also plentiful in the Isle of Man. The fronds are sometimes ten inches long. It makes very handsome specimens for the herbarium.

3. *R. PALMETTA* (Fan-like).—Fronds of a rosy red, and more or less forked, fan-shaped; "rather rigid, and not adhering well to paper."

4. *R. CRISTATA* (Crested).—I have only seen one specimen of this rare plant, kindly sent me by the Rev. Dr. Landsborough. Harvey speaks of it as very rare, and quite a northern species. "Fronds about an inch long, divided near the base into several main branches; substance membranaceous; adhering closely to paper in drying."

5. *R. CILIATA* (Fringed).—Frond thick, and of a purple-red; much lobed, and fringed with ciliae; on rocks and stones.

6. *R. JUBATA*.—On rocky shores; fronds lanceolate, narrow, and becoming much more so at the top; colour dull red; adhering well to paper when not too old. This plant varies much. It is not uncommon on the Cumberland coast.

7. *R. PALMATA* (Hand-shaped).—This is the well-known *Dulse* of Scotch, and in Ireland is called *Dillisk*; happily it is very common, and is much used as an article of food, either raw or cooked; the shorter plants are thought the best; sheep feed upon it. The frond is wedge-shaped, broad, and much divided. It grows on the stalks of *Laminaria digitata*, as well as upon rocks. I extract the following passage from Dr. Landsborough's "British Sea Weeds": "Dr. Greville says, that *Dulse* is the true *Saccharine Fucus* of the Icelanders. According to Lightfoot, it is used medicinally in the Isle of Skye, to promote perspiration in fevers. In the islands of the Archipelago, it is a favourite ingredient in ragouts, to which it imparts a red colour, besides rendering them of a richer and thicker consistence. The dried frond, like many other alga, when infused in water exhales an odour resembling violets; and Dr. Patrick Neil mentions, that it communicates that flavour to vegetables with which it is mixed. Dr. L. also says, that by the Highlanders it is called *Duillisk*, which is a word compounded of two Gaelic words, *duille*, a leaf, and *uisge*, water, i.e., the leaf of the water. From *uisge*, is derived the word

whisky; and, with the addition of *baugh*, life, we have the usquebaugh of the Irish (*aqua vite*), water of life; with how much more propriety might it be called the water of death! The Highlanders and Irish used to dry it in the sun, and chew it as they now do tobacco.

3. SPHEROCOCCUS.

Fronde cartilaginous, compressed, two-edged, linear, distichously branched, with an internal rib, cellular. Name from a sphere and fruit.

1. *S. coronopifolius* (Coronopus-leaved).—Fronde cartilaginous, much branched, and, at first sight, not unlike coarse specimens of *Plocamium coccineum*. It is a handsome plant, of a fine red colour; fronds from six to twelve inches long.

It grows on rocky shores, is not uncommon in the south of England and Ireland, but is rare in Scotland. Dr. Greville has found it in Bute; I have had it sparingly from the Isle of Man. S. B.

(To be continued.)

ROUP.

I AM surprised you should admit the publication in your paper of such dangerous theories as Dr. Horner's have proved to be. I have, for a long time, been in the habit of placing implicit confidence in the correctness of opinions recorded in your paper. I am sorry to say I can do so no more. I consider it the duty of an Editor to thoroughly sift such communications, or, at any rate, to caution his readers. I regret to say that I introduced a roup fowl to my stock *entirely* in consequence of Dr. H.'s assurance of this disease being *non-contagious*, and the result has been most disastrous. My only wish is that I could come upon him for damages; I would certainly do it. To think of my losing a score of valuable fowls through such assurance! * * * * I must request the insertion of this communication (or part of it), as a solace to my feelings, and a caution to others.—ELIZA BATEMAN, *Loughborough*.

[Our correspondent is too hard both upon Dr. Horner and ourselves; and we must think her own rashness is most to blame. Dr. Horner stated his opinion rather strongly, it is true; and for ourselves, if our correspondent will refer to page 232, she will see that we there said—"We should no more think of putting healthy fowls into a house and walk where *roup* had prevailed, than we should of putting a healthy horse into a stall where a glandered horse had been living." Besides, Mr. Tegetmeier and Mr. Brent have recorded similar opinions, so that our correspondent was rash in acting as she did.—ED. C. G.]

In addition to the above, we have the following from W. Lort, Esq., of Great Heath, Tenbury, well-known as an experienced breeder of fowls:—

"For the last two months I have been devoting much time to experiments upon rupy fowls. I have now no hesitation in pronouncing Roup highly contagious, so far as Dorkings are concerned, and that Cochin-Chinas will catch this complaint is pretty evident. I have succeeded in giving the Roup to several healthy fowls by allowing the *dead* body of an old rupy cock to remain with them in an out-building for about three days. Three of the fowls thus infected were young Dorkings, and the other a Cochin-China pullet. The former are now quite cured, but the Cochin-China, as she appeared to eat her food well, I was inclined to let take her chance; she died in about a fortnight from the time she took the disease, without having diminished much in weight, and with a crop tolerably well supplied with grain. How these birds caught the disease from the dead one I do not pretend to say. Mr. Tegetmeier, and he is generally pretty sound in his opinions, has intimated that the disease may be communicated by the birds picking the dried matter from the heads of their companions. This might have been the way the disease was taken from the dead bird; but, as I have before said, I venture no opinion as to how the disease was taken: I only know that it was communicated by a *dead* bird, and in a very malignant form. It behoves those who have rupy fowls to remove them at *once* to some dry, clean place, as far as possible from the rest of the poultry.

"That part of your report of the Shropshire Poultry Show which has reference to the *Malays* is somewhat incorrect. The first prize *was* withheld from a pen of old fowls in heavy moult, but my chickens obtained first and second prizes."

THE ROSE GARDEN.

WE have before us the "Supplement," just published, to "The Rose Garden," written by Mr. W. Paul, the well-known Nurseryman of Cheshunt. When we say that it is a worthy continuation of that excellent book, and that the four coloured portraits of Roses are as beautiful as those which have preceded them, we have said enough to commend it effectually to our readers.

The following extract states Mr. Paul's estimate of the recent additions to the various families of Roses.

"In Groups 1, 2, and 3, the 'Boursault,' the 'Double Yellow,' and the 'Scotch,' no valuable additions have been made. In Group 4, the 'Damask,' we have a White Rose, 'Harriet Martineau,' which, during the past summer, was the finest of White Roses. We remember to have seen this variety in bloom four or five years ago, when in the hands of one individual, and were struck with its purity and beauty. For three years, however, it gave but indifferent flowers here, and can therefore at best be pronounced but an uncertain Rose.

"To Group 5, the 'Provence,' we have added an excellent variety in 'Dometille Bear;' like others of the group, it requires a rich soil and good cultivation.

"Group 6, the 'Pompon,' presents us with no additions.

"Group 7, the 'Moss,' has been the most fertile of Summer Roses in the production of new varieties, but it is in quantity rather than quality. Of the forty-three additional varieties here described, I have seen rather more than one half, four of which I can with confidence recommend: these are, 'Duchesse d'Abrantes,' 'Latone,' 'Purpurea rubra,' and 'Princess Alice.' It must be told, however, that many were seen blooming under disadvantageous circumstances; and if at present we are in the dark as regards the quality of the flowers, in habit of growth many of the new kinds are decided improvements. The 'Moss' appears the most obdurate of Roses, almost incapable of improvement by seed; and I believe many of our best varieties are the result of 'sporting.*' The 'Moss Princess Alice,' first offered for sale this year, is the first-fruit of a sowing made in the Cheshunt Nurseries in the Spring of 1847; so slow is the process of blooming, proving, and bringing into a saleable condition, the varieties of this group. It is a great improvement on the general run in regard to growth, which is so vigorous, that it quickly forms a large umbrageous tree, flowering abundantly: the flowers resemble the varieties of the 'Alba,' being blush, with pink centres.

"It must be a source of surprise to those cultivators who are not acquainted with the commerce of the Rose, that the 'French Rose' (Group 8) has of late produced no new varieties worth notice. How is this? It is that the group has been so many years cultivated, and consequently improved so much, that floricultural skill could go no further? Certainly it is one of the oldest groups, and counts more varieties than any other; but there is ample room for improvement yet. The reason is not this: it is, that the Summer Roses generally are at a discount. A good seedling French Rose is as difficult to originate as a good seedling Perpetual; and, when obtained, does not realise one-fourth the price. The raisers are aware of this, and follow that course of culture which promises the greatest recompense.

"Let us pass to the next group, 'Hybrid French,' which offers one variety, 'Comtesse de Segur,' of great beauty. The flowers are neither large nor full, so that it scarcely answers as a Show Rose; but they are exquisitely shaped, and of a very pleasing colour.

"Group 10, the 'Hybrid Chinese' has received several additions. One only, 'General Lamoricière,' seems to require particular notice. It differs widely from its congeners. The flowers are pink, the petals increase in size from the centre outwards, so that, although perfectly double, they

* See "Rose Garden," Division II, p. 32.

are hollow in the interior, like a cup. It often blooms in the autumn, and, we doubt not, will eventually do so constantly, and thus become a 'Hybrid Perpetual' Rose.

"The 'Hybrid Noisette' (Group 11) presents us with nothing new; but the 'Hybrid Bourbon' (Group 12) has been more generous. Frederic the Second is a capital Climbing or Pillar Rose, with large purplish-erimson flowers, well shaped, but not quite full. Paul Ricaut is certainly one of the finest of Roses: the boldness of growth, and the rich bright crimson hue of the flowers, must render it an universal favourite. It is equally good for a Standard or a Pillar. Vivid (Paul's) is something of the style of the latter. It is a smaller flower, but of a richer colour, and far more velvety: it is of vigorous growth, very hardy, and will form one of the most Striking of Pillar or Climbing Roses.

"The remaining groups of Summer Roses offer nothing very remarkable. We were looking with hope towards the Roses from China, introduced by Mr. Fortune; but these, however interesting in a botanical point of view, do not possess the attributes required by the florist. Fortune's Climbing Yellow, if hardy, may make a valuable addition to our Climbing Roses; and the Banksian Fortumiana will probably make a useful Wall Rose, more showy than the old variety, as its flowers are twice the size.

"We now pass the second class, 'Autumnal Roses,' the first five groups of which require no special notice.

"The 'Hybrid Perpetual' (Group 27) has, within the last five years, given us more fine new varieties than all the other groups together. Sixteen years ago there was but one variety: at the time of the publication of the 'ROSE GARDEN,' 1847-48, there were 107; and now we have no less than 257; giving an increase of 150 varieties in five years! Some of these are of surpassing loveliness, and we shall proceed to note the names of those which have most delighted us, referring to pp. 15—22 for descriptions of them:—Alexandrine Bachemeteff, Angelina Granger, Auguste Mée, Baronne Hallez, Baronne de Heeckeren, Blanche (Portemer), Caroline de Sansal, Cheraeu, Comte Odart, Comte de Nanteuil, Destigny, Duchesse de Praslin, Duchesse d'Orleans, Enfant du Mont Carmel, Eugène Sue, Ferdinand Deppe, General Bedeau, General Brea, General Castellane, General Cavaignac, General Negrier, Graziella, Inermis, Joan of Arc, Lady Stuart, Laura Ramand, Louise Peyronny, Madame de Manöel, Madame Ducher, Madame Fremion, Madame Guillot, Madame Louise Thenard, Madame Pepin, Madame Rivers, Mère de St. Louis, Noemi, Paul Dupuy, Prince Leon Kotchouby, Queen Victoria (Paul's), Rosine Margottin, Salvator Rosa, Souvenir de Leveson Gower, Standard of Marengo, Triomphe de Paris, Volta, William Griffiths. This may appear a long list, but it may be depended on as containing the names of varieties of first merit only. It were easy to add as long a list of other interesting varieties, well worthy of culture; but these we consider altogether indispensable to every amateur.

"If to the next group (28), the 'Bourbon Perpetual,' so many varieties have not been added, it is yet as remarkable for improvement: we may almost say it has given birth to a new style of flower, at the head of which stands Louise Odier. These Roses, many of which were originated at Lyons, are of vigorous growth, producing long shoots well clothed with handsome shining foliage. The flowers, if well formed, are not generally large, therefore they cannot be recommended as Show Roses; but they flower so abundantly throughout the autumn, which many of the 'Hybrid Perpetuals' do not, that they are even more desirable where the object is to have a good supply of Roses late in the year. Louise Odier, Colonel Foissy, Dr. Juillard, Prairie, and Reine Mathilde, are the most striking novelties. If allowed to look into the future, we should assign to this group a distinguished position among Roses at no distant period.

"Group 29, the 'Rose de Rosomène,' furnishes a remarkable Rose in 'Comte Bobrinsky;' the habit is dwarf; the flowers varying much in quality and colour: opening sometimes beautifully, and almost scarlet. In 'Souvenir de Madame Lille' we have a seedling from 'Geant des Batailles': the flowers are much darker, rich in appearance, and nicely cupped.

"In group 35 we find the 'Tea-scented.' Among them, Canary is pretty in bud, but only semi-double when expanded. It appears a vigorous, hardy kind, and the buds

have a charming effect on the tree in the distance. Madame Villermoz is a fine bold Rose, with handsome foliage. Sombrenil is also a variety of great promise. The past summer has been most unfavourable for these Roses, consequently it is difficult to form a judgment of many that remain; but, as far as we can at present pronounce, we are not sanguine in regard to the new kinds.

"The 'Bourbon' (Group 36) has given us darker and brighter flowers, both of which were much wanted. Apolline, Aurore du Guide, Jury, Madame Cousin, Madame Helflein, Prince Albert (Paul's) Reveil, Scipio, Sir J. Paxton, Souvenir d'un frere, and Vorace, are the best of the numerous kinds recently added, and often continue flowering till the blossoms are destroyed by frost."

BEE-KEEPING FOR COTTAGERS

(Continued from page 311.)

Condensers—Feeders, if left on after feeding is over, will fulfil all the purposes of a condenser: a condenser, as its name imports, is used for collecting and condensing the perspiration that in the winter, rises from the bees, and, unless carried away, settles upon the combs, and causes them to turn mouldy and breed disease. If you have not as many feeders as you have hives (and it is not at all necessary you should have, for none of your hives, if properly managed, ought to want feeding at all), a large gallipot, or bee-glass, turned upside down in a zinc trough, or even placed upon a piece of metal, with a large hole in the centre, and set over the hole in the centre of the hive, will make as good a condenser as anything: should a piece of metal and not a trough be used, it will be necessary, every three or four days, to turn up the gallipot or glass, (first slipping a plate of tin or zinc under it, to prevent much cold air entering the hive), and wipe away the moisture that will have collected on it, and the metal: the condenser, in winter, tends as much as anything to preserve the health of the bees.

Pumigators.—The kitchen bellows may be easily used for smoking hives; it will only be necessary to have a tin tube, about three inches long and two inches across, made to fit over the air hole; at one end of it there must be rivetted a piece of perforated zinc; at the other there must be a movable lid made of a similar material. It will also be well to have a flat box, about two inches broad, four inches long, and half-an-inch deep, with a piece of perforated zinc fitted to one end, and a tube somewhat larger than the nozzle of the bellows fitted to the other, so as to make a box something like a flat watering-pot rose: this box is to be inserted, on operating, into the mouth of the hive, and fixed there with some bits of rag, or list: the object of it is to give the operator a freer use of his hands than he would have if the nozzle of the bellows were to be introduced into the hive. The material to be used in this is what is called Devil's Snuff Box, Fuzz-ball, or Puff-ball; it should be gathered nearly ripe, dried in the sun, and kept dry. Country folk can generally get this pretty easily from the fields; when, however, it cannot be procured, the *Rocodium cellare*, or dark cobweb-kind of stuff that may be found in most wine-vaults, will answer the purpose equally well.

Bee-Dress and Gloves.—Whatever may be said about coolness in operating being the best protection against stings, it is always desirable to be protected: in fact, the necessary coolness can only be obtained after many years' experience, and then only by a favoured few. Do not, then, despise a bee-dress and gloves. The thick leather gloves used by hedgers, drawn well up the coat-sleeves, or a pair of thick woollen gloves, lengthened gauntlet fashion, by having a pair of old stockings with the feet cut off sewn to them, will effectually protect one's hands, whilst a thin gauze or lino sack, into which to put the hat, head, and shoulders, will do the same for the face: the lower end of this sack will be slipped inside the jacket, which must be then buttoned up; it will be even better to make armholes in the sack (which may be kept tight to the arms by means of india-rubber bands), and run a string into its lower end, so as to be able to draw up the whole bag-fashion tightly under the arm-pits: the broader the brim of the hat the better. As bees are unable to withdraw

their stings from *leather* gloves, it will be as well, if possible, to have the backs of them covered with some fur,—hare or rabbit-skin, for instance,—having, of course, the fur outwards.

Knives.—The two following knives will be found very convenient in operating, more particularly the latter of them; without it, great difficulty is experienced in cutting the combs from the tops of the hives. The first is merely a strong knife, made square at the end, and sharpened at the end and on both sides, so that it can cut downwards or either way; the second is a thin rod of iron, about a quarter-of-an-inch square, having a lancet-shaped head, welded at right-angles to the rod, and sharpened at both sides also, that it may cut both ways. Both these knives may be made of a good hard bit of iron.

Sieves.—One or more perforated zinc sieves, according to the number of old hives to be taken up every year, must be had for draining the honey from the combs. A sieve of this kind may be readily made by nailing a circular piece of perforated zinc to the hoop of an old worn-out hair sieve, or by making a rough box with sides, each about six inches broad, and with a piece of perforated zinc for a bottom. A common colander answers the purpose of drawing honey, perhaps, as well as anything.

Blocks.—These are merely small pieces of wood of the same depth as the entrances to the hives, and are made use of for narrowing the entrances in the months when the bees are idle, and when the hives are likely to be attacked by robber-bees: they should be of various breadths, varying from half-an-inch to an inch-and-a-half. Other and larger blocks will also be required for placing before the hive entrances in cold, or snowy weather, to prevent the sun's rays striking on the already narrowed entrances. Small pieces of inch-stuff, about three inches square, answer this purpose as well as anything: placed in front of, and nearly close to, the hive entrance in winter, they, in connection with the hackles and jackets already described, will effectually ward off the sun's rays and reflected light, and will assist in keeping the bees quiet.

Sundries.—You must also have several pieces of wood, about six inches square, to lay over the middle holes of the stock hives when the top hives are removed; several flat pieces of zinc or tin, of various sizes (from twelve inches by eight to six inches by six), some of the smaller pieces perforated; a small stoppered bottle of liquor potassæ, or cold lotion; a bit of tobacco; and some bits of linen or woollen rag: all these, as well as many of the smaller articles already described, and other little things that will suggest themselves in practice, may be conveniently kept in a box in some handy place where they may be got at any time.

Painting, though not exactly "apparatus," seems a proper end for this section. Everything about the bees that can be, should be well painted; things last three times as long and look infinitely neater in consequence. Painting can be done on fine, dry, mild days in January and February without injury to the bees.

(To be continued.)

SILVER-SPANGLED HAMBURGH'S CHARACTERISTICS.

In a recent number of *THE COTTAGE GARDENER*, I noticed, with much pleasure, some remarks made by you in reply to a letter written by Mr. John Brown, of Birmingham, on the subject of poultry judges having some positive rule to guide them in their decisions, more especially as regards Spangled Hamburg fowls. From the various and conflicting opinions we hear from persons who may be supposed to have some knowledge of the characteristics of this breed of poultry, and from the apparently extraordinary decisions we so frequently see at exhibitions, it is perfectly evident the time has now arrived that some positive rules should be laid down for the guidance of both breeders and judges.

Having, myself, for some time past, paid considerable attention to the Silver-spangled Hamburg fowl, I beg to request you will allow me a small space in your *Journal*, to express my ideas of what I consider constitutes the prin-

cipal characteristics of this elegant and useful variety of poultry, and in my views respecting them, *I know* I am supported by many of the largest breeders of this class of fowl.

The general impression amongst the best breeders is, that a perfect *Silver-spangled hen* should have a double, rosy, and erect *comb*, and not a lop-sided one, which we so frequently see; white *ear-lobes*, and, above all, every *feather*, from the head to the extremity of the tail, should be perfectly white, tipped at the end with black; this, from the feathers over-laying each other, gives an alternate black and white spot, producing in a perfect bird that beautiful spangled appearance from which this variety takes its name.

The *male bird* of the Silver-spangled breed should also have a double, rosy, and erect *comb*, terminating in a point at the back; white *ear-lobes*, and every *feather* white tipped with black to the extreme end of the sickle feathers of the tail, but from the great length of the neck and saddle-hackle of the male bird, it is almost impossible to produce that spangled appearance on the back which we always see in the male bird, and it is from this cause alone that the Silver-spangled cock shows so large a proportion of white feathers on the back.

Having recently seen a tendency among some of our poultry judges to award prizes to fowls in this class having the *hen's tail*, thereby showing a more spangled appearance on the back, I beg to call their attention to this particular point, that the male bird of the Silver-spangled breed ought to possess the drooping saddle-feathers, which adds so much beauty and elegance, as compared with the cropped and narrow appearance of the *hen's-tailed* birds.

I am aware that some of our poultry judges will differ with me in opinion as regards the retention of the saddle-feathers, but I do know, that in the districts of Yorkshire and Staffordshire, where this class of fowls is principally bred, none but birds having the saddle-feathers would be considered pure, and a *hen's-tailed* cock would be said to be crossed with the Golden-spangled.

This is a question upon which many of our judges are not agreed, and it is one that, for the guidance of breeders, ought to be settled. One judge awards prizes to *hen's-tailed* birds, another will not notice them. So well is this understood amongst many exhibitors, that when the judges are known, they exhibit accordingly.

Surely this ought not to be. Let us have some definite rules to guide us, and, depend upon it, first-rate birds will be produced. I hope you will render us your aid and assistance in endeavouring to settle this disputed question.—AN ADMIRER OF THE SADDLE FEATHERS.

[We shall be glad to have the opinion of other breeders of Spangled Hamburgs on this point.—ED. C. G.]

SILK CULTURE.

THE cultivation of Silk was confined for ages to China alone, and the Chinese guarded the secret from whence they derived such immense wealth with such extreme jealousy, that many of the ancient writers believed it to be a vegetable product, which we may infer from the following lines:—

"Nor flocks, nor herds, the distant Seres* lead,
But from the flowers that in the desert bloom,
Tinctured with every varying hue, they cull
The glossy down, and card it for the loom."

Marsellianus gives a more correct description from whence the Seres produced such a costly material. He says, they have an insect, which they rear in buildings, spinning a fine thread; and this statement becomes interesting, for it at once removes a mistaken notion that the Silk-worm, in countries where it is indigenous, is left to its natural state. On the contrary, wherever silk is cultivated as an article of commerce, the Silk-worm is artificially reared, and it is to the care of man for these little silk manufacturers that we are indebted for their beautiful filament.

It is well-known how reluctant the Chinese are to admit strangers, but, notwithstanding all their precautions, two Persian missionaries penetrated the country, and to them is accorded the credit of introducing this valuable branch of

* Seres was the name by which the ancients designated the Chinese.

industry into Europe. They observed with interest the labours of the little insect, and made themselves acquainted with the various processes of fabricating its produce, and succeeded in obtaining a quantity of Silk-worm eggs, which they concealed in a hollow cane, and safely conveyed them to Constantinople, in the year 552. The eggs were hatched in due season, and the insects thus produced were the progenitors of all the countless generations of Silk-worms in Europe, and have become, to many countries, a valuable branch of industry. From Constantinople it spread to Greece, Spain, Italy, France, Germany, and Holland. Even in Sweden and Russia, silk is successfully cultivated; and we trust, that the time is not far distant when England, so justly renowned for its industry and its inventions, shall also count its silk cultivators. Pullen says, in his Essay, "A lady, with a little trouble, may easily provide herself with a suit of silk."

It has been proved that 4,000 Silk-worms spin more than one pound of silk, which will make sixteen yards of *Gros de Naples*, sufficient for a lady's dress; and the time from the hatching of the eggs to the reeling of the silk is no more than six weeks. Attempts have often failed, by trying to substitute different food for that which is natural to the Silk-worm, for the insect will not thrive on any other food but the Mulberry-leaf; and Monsieur L. de Long Champs asserts, that the Silk-worm fed upon the white Mulberry-leaf produces a much finer silk than those fed upon the black; the former having the advantage also of coming into leaf at least a fortnight earlier than the latter, and of being most easily propagated.

The following is a statement of the result obtained by Monsieur Nourrigat, cultivator at Lunel, in the Department of the Herault, in France:

From 24 ozs. of eggs he obtained Silk-worms sufficient to produce 32 cwt. of cocoons; the worms requiring 321 cwt. of leaves, or 100 leaves for every five cocoons.

The cocoons were sold for	£306 10 0
The expenses were	108 5 0

The Nett Profit	£198 5 0
-----------------	----------

BOMBAY.

DISEASES OF POULTRY.

VERTIGO AND APOPLEXY IN LAYING HENS.

THE regularity with which certain diseases recur at particular seasons is not the less remarkable in feathered than in unfeathered bipeds. The commencement of the laying season has furnished me with an unusual number of cases of vertigo and apoplexy. The history of these cases is nearly, in all instances, perfectly identical; the birds well fed during winter become very fat, and as soon as the egg organs become active an undue determination of blood to the brain takes place, causing vertigo, when the hen staggers or runs round and round; in severe cases a small vessel gives way, and an effusion of blood takes place, which, pressing on the brain, causes apoplexy. (It may, perhaps, interest some of my professional readers to state that I have invariably found the effusion to take place at the base of the brain, and chiefly around the medulla oblongata; in fact, so low down does the extravasation extend, that it may be noticed in all cases where it exists by merely removing the atlas, without opening the skull; to do which, without injuring the brain, is attended with very considerable trouble.) Cases of vertigo may usually be successfully treated by holding the head of the bird under a stream of cold water, taking care that it does not run into the mouth, or the bird may be drowned; this should be followed by an immediate dose of five grains of jalap in powder, which, by its irritating and drastic action, will cause a determination of blood from the head to the digestive organs. (I may mention, in passing, that this is one of the very few cases in which jalap is a desirable medicine for poultry, its violent and weakening effect rendering it much less desirable than other aperients, as castor oil, &c.) This treatment, followed up by low unstimulating diet for a few days, will generally be quite successful. Should, however, the vertigo continue, or should apoplexy supervene, immediate recourse must be

had to copious bleeding; to perform this operation, nothing more is requisite than to stretch out the wing, on the under side of which may be observed several veins; the largest should then be freely opened with a sharp-pointed penknife, or lancet, when, if the finger is pressed on the vein above the opening (that is nearer the body), the blood, being arrested in its course towards the heart, will flow freely, and continue to run as long as the finger is kept in that position, ceasing on its removal. The quantity taken away must, in all cases, depend on the urgency of the symptoms; in apoplexy, the only chance of saving the bird is to continue until consciousness returns; and in vertigo, until the bird on being placed on the ground ceases to run round and round.

By adopting these means I have saved every bird affected with vertigo that has come under my notice; whereas, if left alone the disease generally terminates in apoplexy; and in the latter disease I have saved two valuable birds which I had the opportunity of seeing immediately after the attack.

I may mention, that these diseases occur also in male birds, although, as far as my experience extends, less frequently than in laying hens.—W. E. TEGETMEIER, *Willesden, near London.*

ROYAL SOCIETY OF VAN DIEMEN'S LAND.

THE monthly meeting was held on 10th September; Sir W. T. Denison, President, in the chair.

Among the presentations were, from Mr. H. Hull, seeds of *Martynia fragrans*, from the Mauritius, for the society's gardens.

From the Rev. Edward Freeman, of Brown's River, a specimen of drift wood cast up on the sea-beach there, upon which were fixed a congeries of curious ova-cells of a shell-fish.

From Sir W. T. Denison, a packet containing nineteen species of seeds from China, for the gardens.

From Francis Smith, Jun., Esq., a packet containing 120 species of Indian seeds, for the gardens.

A case containing thirty-nine plants has been forwarded to Auckland, and a case of New Zealand plants is expected in return.

A member suggested the great difficulty generally experienced in cultivating the conifers of Tasmania. Mr. Archer informed the meeting that his attempts with them had usually been successful, and that he had now, in a thriving condition in his garden at Cheshunt, (immediately at the foot of the Western Mountains), six pieces.

Mr. W. Archer submitted for examination, and explained at some length, a series of drawings made by him of certain galls or tuberosities, with turret-like processes, upon twigs of the *Casuarina quadrivalvis*, laid before the society a few months since by Dr. Officer, and of the animal contained, and promised to supply a description in writing for the next monthly meeting.

Mr. Archer drew attention to a small brown speck observable on the surface of oranges brought here from Sydney this season, and to the fact, that under each of these brown fungus-like scales he had found a minute living insect, little more than one-hundredth-of-an-inch in diameter.

Mr. Archer also laid on the table a curiously convoluted and fantastic growth of a shoot of *Casuarina* for inspection.

TO CORRESPONDENTS.

. We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of The Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

CUCUMBER AND MELON HOUSE.—T. T. says,—“In No. 259 of THE COTTAGE GARDENER, I saw a plan of a ‘Cucumber and Melon House’ which was much recommended. We are about erecting a small house to grow early Cucumbers and late Melons, and to put a few stove plants in to flower which will not bloom in our greenhouse. We have five lights, 8 feet in length, and 3 ft. 6 in. wide,

which is sufficient for a house for us; it will have one roof to train the plants to. I intend having a short back roof, 2 ft. 6 in. wide, the two ends bricked to the roof. I intend the boiler to be at the east end, and the door at the other. My enquiry is, will the top pipes running in the chamber from one end to the other be sufficient to heat the house for Cucumbers during winter; and what will be the expense of the boiler, and the sized boiler required, and pipes; also, where they can be obtained; also the lights; it fronts the south; and is it best to have the two pipes in the chamber? I was thinking of having a flue along the back of the house, but only for occasional use." Two pipes in such a chamber will be quite sufficient to heat such a house, provided you have openings in the sides of the chamber to allow heat to get into the atmosphere of the house when necessary. It will also be necessary, in the case of Cucumbers and Melons, to have troughs fixed on such pipes, as mentioned in the plan, No. 259, p. 456; or, if you wish to avoid that extra expense, the pipes should be surrounded with rubble, rough gravel, and then, by pouring water amongst that rubble, you may have moist heat at command. By thus covering your pipes, you may also dispense with the expense of a slate covering over the chamber. From nine to twelve inches of rough, hard stuff over the pipes will be sufficient. If with only two pipes, they will require to be four-inch ones. These will be quite sufficient, if you carry your flue through the back wall, as that will give you a dry heat. If you did not have the flue, and yet wanted fruit all winter, you would be safer with two three-inch pipes for bottom-heat, and two for top-heat. You would see the mode of doing this the other week. The expense of pipes and boilers was given last year; that will greatly depend upon the distance; the smallest boiler, costing about £2 10s., would be sufficient. Lights will depend on the glass; about 1s. per foot would be a fair price; but you would see advertisements. Altogether, if not objected to, we would have pipes for top, and others for bottom-heat, to turn off and on at pleasure. We have no doubt, however, that the plan in No. 259 will answer admirably; but your house with the hipped roof will be much larger in proportion for your two pipes than that house is with four; the heating power would be as two to four; the space to be heated more than two to three. If expense is no object, you cannot keep too close to the mode in No. 259.

SCALE ON FRUIT-TREES (Ibid).—We have tried water almost boiling for this, and also a mixture of oil and grease, but both, though killing the scale, injured the trees. We have seen a mixture of lime, soot, and clay, tried with good effect. The insects were smothered, and the mixture dropt off before the bark was injured.

INDIAN-RUBBER PLANT—FICUS ELASTICUS (Peckham).—We fear your plant has been kept too cold, and, perhaps, in these circumstances, too wet. Try a sharp knife, and make an incision in a fair-sized shoot. If no white juice comes, you may almost despair; if that exudes, keep the plant in the warmest part of the greenhouse, if you have no better place; sponge the shoots on a sunny day, but give very little water to the roots until the buds begin to swell. Let the water used for syringing, and also for watering the roots, be warm, say 75° to 80°. It ought to be all right if you gave it from 50° to 60° during winter. Most likely the frost has had access. If there is healthy juice in it, it will break again. We require an address from writers and critics; but enquiries may, or may not be so accompanied.

HEN-FEATHERED SILVER-PENCILLED HAMBURGH COCK.—E. A. asks—"Whether a Hen-feathered Silver-pencilled Hamburgh Cock is an acknowledged variety?" If by "variety" is meant any permanence of this peculiar feature in the progeny, the answer must be in the negative. Such birds are occasionally seen, but we cannot conceive how they could be thought desirable in the Pencilled Hamburghs, although the more perfect development of the spangle usually consequent on this peculiarity might be regarded as some compensation to a spangled pee, for the absence of the very characteristic sickle tail that distinguishes the Hamburgh family.—W.

TREE CARNATIONS (Mary).—You will be quite right to take shoots off your tree Carnation, for cuttings, early in the spring; and where you take them from leave only one or two joints from the old centre, so that the next growth may come without being on long legs; half the Carnation trees are soon spoiled for want of pruning in time. Whether the shoots so cut at the beginning of March will make new shoots so strong as to flower next summer is another question. If the tree is in very good health, is strong, and has good roots, these new shoots will be sure to flower after the middle of July.

TURF COUNTRY (Ibid).—How lucky you are to have turf instead of coal, if your turf is that kind of hard, black peat, which they cut in the form of bricks. When that kind of earth is tried in a loose heap, and some of it is run through a rough sieve, and kept dry in a shed, it is the best thing in this world to keep other things from rotting or moulding, and, therefore, the best thing to plunge pot plants in, either in a pit or frame; a little water will not hurt it much, but the drier it is kept the better. The keeping qualities of your stock of *Delphinium* is as follows:—1. Punch; 2. Compactum; 3. Commander-in-Chief; 4. Cerise; 5. Tom Thumb; 6. Unique; 7. White Ivy-leaf; 8. Mangle's Variegated; and 9. Golden Chain; all except 9 will do in a dry, cold pit, without any fire heat, and 9 is a sociable kitchen-window plant, hot and dry;—make cuttings of every bit of it as soon now as your bed is ready.

FLOWER-GARDEN (Rev. E. H. C.).—Your geometric garden is exceedingly well planted. When we saw No. 1 to be with *Delphinium sinense*, we handed the letter to a lady who happened to be in the room, and read off the colours of all your beds from the plan itself, and we only missed in No. 11.—No. 10 requires to be mixed, to agree with 11, and also not to disagree with 13, the planting would then be perfect, according to the prevailing taste. If we were quite sure of the boundary line, and how the walks to and from 8 and 9 terminate, we would engrave this plan for the sake of the planting.

FEEDING BEE (A Tyro).—Go on to supply barley-sugar until your bees refuse to eat it, which will, in all probability, be in April. If No. 2 has a good supply of barley-sugar always in store, say three or four sticks, at least, there is very little cause to fear of their being carried through the winter, and making a good stock for next year, but all depends upon their having food and their taking it. Buy *Payne's Bee-Keeper's Guide*.

CUCUMBERS (W. W.).—These, not ripening their fruit in your greenhouse last summer, were probably supplied with something wrong at the root; either the soil or the watering were deficient. It is impossible to say, positively, where the error was unless we knew what you did.

DEVON AND CORNWALL POULTRY SHOW.—B. J. Ford, Esq., of Ide, near Exeter, took a first prize for Partridge-coloured Shanghaes, and not a second, as stated in our report.

GOLDEN-PENCILLED HAMBURGH (An Anxious Enquirer).—Your hens not laying this year, though so prolific last year, indicates that they are probably too fat. Give them less nutritive food for a few weeks.

SHANGHAES NOT LAYING (Darlington).—Your pullets are certainly too well fed. Stint them to a quarter-of-a-pint of barleymeal and bran mixed, and a quarter-of-a-pint of wheat or barley a-head per day. The symptoms you mention, at present are those of a severe cold. Give the invalids a desert spoonful of castor oil, and keep them in a dry, sheltered shed for a few days.

CAYENNE PEPPER IN PODS (T.H.).—Either the foreign or the English will do for Poultry. Such stimulants are never given to our fowls.

EMIGRATION.—H. C. says—"A party, anxious to emigrate to Australia as an agriculturist, wishes to know what seeds he should take, both agricultural and horticultural? Which part of the country is best adapted for agricultural pursuits? What breeds of Cattle, Poultry, and Sheep would be best to take? (Query—Should any be taken; or purchased when there?) How is ground obtained there, by purchase? or are there parts free to all who like to clear the land and cultivate it? What kind of field and garden implements should be taken? What books might be read with advantage on the subject?"

INVALID FOWLS (M.).—We can only suggest that they need more nourishing food, such as wheat and Indian-meal; but it is quite impossible for us to give an opinion without knowing how or where they are kept.

ORCHID CULTURE (W.W.).—We do not know whether Mr. Appleby intends to make arrangements for publishing these in a separate form.

EGGS FROM LATE PULLETS (S. T.).—We should have no objection to rear chickens from eggs laid by pullets hatched last May, especially as they weigh nearly 6lbs. each. We never sit a hen after the beginning of June, nor earlier than the middle of February.

PLASTER FOR WOUNDED PLANTS (H. H., Jun.).—The cut surfaces of Rose-Stocks, and similar wounds, do not require any other covering than a little thick paint. Pressure is injurious to such wounds.

AWNING FOR ROSES (J. F. T.).—Your friend's Roses in America, which were scorched up last summer, though grown "under the shade of trees," probably suffered on account of being so situated. The weather for Roses can scarcely be too hot in this country, if the soil is rich and well supplied with moisture. The roots of the trees beneath which they were grown probably robbed the Roses of the nutriment which would have enabled them to withstand the heat. An awning would prolong the duration of the bloom, but manure, and water to the roots, would best carry them through great drought. The seeds you mention may be obtained in England as good as in France.

IODINE FOR THE POTATO DISEASE (M. S.).—We know nothing upon this subject. There is some iodine in all Sea-weed. The grass beneath the Cedars dies from want of light.

SPANISH COCKSHELL (A. B. C.).—Write to Capt. Hornby, Knowsley Cottage, Prescot, Lancashire.

SUDDEN DEATH OF POULTRY (W. E.).—The cock forwarded to Mr. Tegetmeier having been sent to Tottenham, did not reach him. The bird, doubtless, died of apoplexy; a description of the symptoms, and treatment of which, will be found in the present number.

Advertisements.

SEEDS DIRECT FROM THE GROWERS, (Carriage Free) the most effectual means to prevent disappointment.

SUTTON'S CATALOGUE for 1854 is just published, and will be sent post-free, on receipt of one postage stamp.

JOHN SUTTON & SONS, Seed Growers, Reading, Berks.

IMPROVEMENT OF GRASS LANDS.
SUTTON'S RENOVATING GRASS SEEDS FOR

IMPROVING OLD PASTURES.—Many Old Upland Pastures, Parks, and Meadows, are nearly destitute of Clovers and the finer and more nutritious sorts of Grasses, in which case we are in the practice of furnishing such sorts only as are wanting. If the Seeds are sown early in the season, the improvement in the Pasture will be very considerable, and at a small expense.

The following is similar to many other letters received from former purchasers:—

From D. T. Cunynghame, Esq., Wellesbourne, Warwick, Nov. 1852. "The meadows that were renovated with your Seeds are looking very well. I cut nearly 2 tons of hay to the acre, and three years ago the same land hardly produced half-a-ton per acre. The Garden Seeds I have had from you exceed by far any that I have bought elsewhere."

Quantity of Seed required, 8 lbs. to 12 lbs. per acre. Price 1s. per lb., Carriage Free.

Address, JOHN SUTTON & SONS, Seed Growers, Reading, Berks. N.B.—We have a very fine Stock of Mangold Wurtzel and Carrot Seed, and other Agricultural Seeds.

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kalender; and Published by WILLIAM SOMERVILLE ORR, of Church Hill, Walthamstow, in the County of Essex, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—February 16th, 1854.

NEW SEEDS—GROWTH of 1853.—RENDEL'S COLLECTION OF GARDEN SEEDS, FOR ONE YEAR, will be sent out as usual by the Subscribers.

The collections have given universal satisfaction, and they will be found sufficient to supply a garden during the whole of the 12 months.

No. 1.—A complete Collection, to supply a large garden for 12 months, including 20 quarts of the newest and most approved Peas, for early, medium, and late crops; 10 quarts of Beans, £ s. d. and full quantities of all other kinds of vegetable seeds . . . 3 0 0
For the detailed quantities contained in the No. 1 Collection, see back page Gardeners' Chronicle, Jan. 7, 1851.

No. 2.—A complete Collection, in reduced quantities, for a smaller garden 2 0 0
No. 3.—A complete Collection, ditto 1 5 0
No. 4.—A small and choice Collection 0 15 0

*. All orders above 20s carriage free (see PRICE CURRENT), and all orders above £5, delivered carriage free to every Railway Station in England and Wales, and to every Steam Port in England, Wales, Ireland, and Scotland.

WILLIAM E. RENDEL & CO., Seed Merchants, Plymouth.
ESTABLISHED 1786.

The quantities contained in the above Collections will be found in our PRICE CURRENT AND GARDEN DIRECTORY, just published.

WHITE MULBERRY TREES.—EXPRESSLY CULTIVATED FOR THE REARING OF THE SILK WORM, at 10s, 15s, and 20s per hundred. Cuttings, 5s ditto.

SILK-WORMS EGGS, 1s 6d per thousand.
Post-office Orders or Stamps, on receipt, duly attended to. Address, Mr. J. R. EVANS, 8, Cork Street, Bond Street, London; or Mr. G. BALCHIN, Spring Place, Godalming, Surrey.

POLYANTHUS SEED.—To the lovers of that beautiful early spring flower, the POLYANTHUS.—JAMES WOODS has again to offer a quantity of Polyanthus seed, which he has this year saved with more than ordinary care from about eighty named and good faced flowers, which he can recommend with confidence, with directions for sowing. Price 1s per packet, or sent free on receipt of thirteen postage stamps.

J. W. has a quantity of Ranunculuses, good, old, superfine, named sorts, in one general mixture, which he will send free by post, at 4s per 100, or 35s per 1,000, on receipt of post-office order or postage stamps, to JAMES WOODS, Florist, Harwich, Essex.

P.S.—Plants of Polyanthuses will be sent out in April, at exceedingly low prices, with blooms on each plant, as the stock must be reduced, as the land is wanted for railroad purposes.

CHOICE SEEDS FOR PRESENT SOWING.—

JOSEPH HENRY KNIGHT, Seedsman, &c., Battle, Sussex, begs to offer the following choice Seeds, which have been saved under his own inspection, and are warranted of the finest kinds. Post Free, in sealed packets, at the prices annexed:—

ASTER GERMAN, in 12 separate colours; many of them have been grown five inches over—the collection for 1s 6d.

ANTHRINUM, from 70 kinds, including the best striped, mottled, and marbled kinds, 6d.

PANSEY, from 100 of the best-named kinds, 1s.

HOLLYHOCKS, from a collection of 50 named sorts, 6d.

SWEET WILLIAM, from 50 sorts, 6d.

VERBENA, from 70 kinds, including the new continental sorts, 6d.

CARNATION, PICOTEE, PINK, and CALCEOLARIA, from the choicest show kinds, 1s each.

Choice Annual Flower Seeds, with full descriptions of the height, colour, time of flowering, and general character, marked on each packet. None but the most approved kinds will be included in any collection; the whole sent Post Free at the prices annexed.

Large Packets for Large Establishments—100 papers, 10s 6d; 50 papers, 6s; 30 papers, 4s. Smaller Packets for smaller Establishments—100 papers, 7s; 50 papers, 4s; 30 papers, 2s 6d; 12 papers, 1s 2d.

Descriptive Catalogues may be had by enclosing one postage stamp.

CAREY TYSO'S CATALOGUE OF FLORISTS' FLOWERS for 1853-4 may be had, post free, for two labels. TREATISE on the ANEMONE, for four labels. Ditto on RANUNCULUS, for eight labels.

RANUNCULUSES: 100 splendid named sorts, 40s to 4 0 0
" 25 superb Seedlings, do. 1 15 0
" 100 fine mixtures from 8s . . . 1 0 0

DOUBLE ANEMONES: 50 fine named sorts 12s . . . 0 15 0
Ranunculus and Anemone Seeds, per paper 0 2 6

IMPORTED GERMAN SEEDS:—Asters, Stocks, Balsams, Larkspurs, Poppies, Zinnias, &c., in named assortments, 2s 6d each; 25 varieties of Annuals, 5s. The above articles can be sent by post.

C. TYSO'S Sovereign assortments, comprising 18 select Ranunculuses and 18 choice Double Anemones, sent postage free for £1 1s.—Wal-hutford, Berks.

SELECTED GARDEN SEEDS.—We beg to offer the following Collections of Garden Seeds:—

No. 1.—A complete collection, suitable for a large garden . . . 3 0 0
2.—A collection of equally choice varieties, but smaller quantities 1 10 0
3.—A collection suitable for a small garden 0 15 0

Nos. 1 and 2 collections will be sent carriage free to any Railway Station in England or Wales.

J. C. WHEELER & SONS, Seed Merchants, Gloucester.

A GENTLEMAN, giving up Pine Growing, has 60 fine Plants, of the best sorts, and in excellent condition, nearly fruiting, to dispose of.—Apply, by letter, C. D., Office of the Publisher of THE COTTAGE GARDENER.

HAWKES'S CHAMPAGNE RHUBARB.—

This most desirable variety is now for the first time offered to the public. It has stood the severest test that can be applied, and has beaten everything in Covent Garden and other London markets, in realizing higher prices, from its magnificent colour and size. It has been seen by the very highest authorities, and pronounced to be a most valuable introduction. In earliness it equals the Prince Albert, but is of a deeper colour, and a much greater bearer. It forces remarkably well, and is very hardy out-of-doors. Mr. Hawkes has placed the entire sale in the hands of DUNCAN HAIRS.

One-year-old plants, strong, 5s each. A few two-years-old, very strong, for sale.

LAING'S MAMMOTH RED CELERY.

This is considered the largest yet grown, attaining the extraordinary weight of from 10lb. to 12lb., and, at the same time, perfectly solid. It is nearly perennial in its habits, as it will not, under any circumstances, run to seed the first season, and it is difficult sometimes the second, when planted out for that purpose. In colour it is a bright red; in flavour unsurpassed, if equalled.

It has been seen growing by many practical gardeners, who deem it a new feature in the garden, from the fact that you may have it nearly all the year. Packets 2s 6d each.

DUNCAN HAIRS, Seedsman, 109, St. Martin's Lane, London.

MITCHELL'S HARDY EARLY CAULIFLOWER.

This is grown precisely as the hand-glass variety, but when removed from the frame does not require the same protection, and comes in immediately after. This is particularly recommended for gentlemen's establishments. The head is not large, but handsome and compact, and is so firm, that you may let them stand from ten days to a fortnight, and they will not get pithy. This is quite a distinct variety. Packets 2s 6d each.

DUNCAN HAIRS, Seedsman, 109, St. Martin's Lane, London.

Post-office Orders payable at Charing Cross.

PYRAMIDAL PEAR-TREES ON THE QUINCE

STOCK.—J. and J. FRASER, Nurserymen, Lea Bridge Road, Essex, beg to offer the above in fine strong Trees, and such as would fruit the first and second year after planting, at the unmercenary prices. These Pears are remarkable for their compact style of growth and prolific bearing. The collection comprises the following fine sorts:—Beurré d'Amanlis, Beurré d'Artemberg, Beurré de Capiaumont, Beurré Diol, Beurré Easter, Beurré Grise d'Hiver, Noveau, Beurré Rance, William's Bon Chretien, Crassane, White Poyenne, Duchesse d'Angoulême, Forle, or Front Pear, Glout Morecan, Haeon's Incomparable, Jargonelle, Louise Bonne of Jersey, Marie Louise, Napoleon, Winter Neils, and Passe Colmar. Price 2s 6d to 3s 6d.
January 13, 1854.

GLENFIELD PATENT STARCH, used in the

Royal Laundry; Wotherspoon's Machine-made Lozenges and Comfits, packed in neat 4 oz., 8 oz., 16 oz., and 7 lb. Boxes, free from colouring matter, which is so much objected to; Scotch Marmalade, Jam, and Jellies, now so universally known for fine quality, prepared by Steam Power, for Home use and Exportation. Sold by all Shopkeepers.
London—WOTHERSPOON, MACKAY, & Co., 66, Queen Street, Cheap-side.
Glasgow—ROBERT WOTHERSPOON & Co., 40, Dunlop Street.

THE ROSE GARDEN,

By WILLIAM PAUL, of the Nurseries, Chessnut, Herts.
"Infinitely the best work ever written on the Culture of the Rose,"—*Bulbous Garden.*

By the same Author, price 1s,

AN HOUR WITH THE HOLLYHOCK.

London: PIPER BROTHERS & Co., 23, Paternoster Row; and all Booksellers.
New Edition, Price 8d; or by Post, of the Author, Kelsale, Saxmundham, Suffolk, 1s.

INTERESTING TO EVERY SPORTSMAN

AND COUNTRY GENTLEMAN.—This Day is Published, price 2s 6d, Part I., to be completed in about Fifteen Monthly Numbers, royal 4to.

BRITISH GAME BIRDS and WILD FOWL. By BEVERLEY R. MORRIS, Esq. The present Number of this splendid and elaborate work contains Coloured Illustrations of—1. The Pheasant; 2. Capercaillie or Wood Grouse; 3. Jack Snipe; 4. Garganey Plover.
GROOMBRIDGE AND SONS, Publishers, 5, Paternoster-row.

TO ADVERTISERS.—THE COTTAGE GARDENER

and COUNTRY GENTLEMAN'S COMPANION (Established 1848), is supplied to Six Thousand Families of the United Kingdom. Amongst its Subscribers are included GARDENERS, POULTRY BREEDERS, and BEE-KEEPERS—PROFESSIONAL AND AMATEUR,—COUNTRY GENTLEMEN and CLERGYMEN. To Advertisers, desirous of communicating with these classes, its columns offer exclusive advantages, and its position as a Family Journal gives to Advertisements referring to articles of domestic consumption a wide and desirable publicity.

THE COTTAGE GARDENER is published in Weekly Numbers, Stamped, and Unstamped, and in Monthly Parts. The terms for Advertisements (which are inserted in the whole impression) are as follows: Five Lines (about sixty words), 3s 6d; per Line additional, 6d.

Wm. S. Orr and Co., 2, Auen Corner, Paternoster Row.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 47.7° and 34.2° respectively. The greatest heat, 64°, occurred on the 28th in 1846; and the lowest cold, 18°, on the 23rd in 1852. During the period 108 days were fine, and on 81 rain fell.

FLOWER-GARDEN PLAN.—No. 12.

This Plan is a duplicate of Plan No. 11, at page 213, and all that I said about that plan refers equally to this one. There were two blocks of beds in No. 11, and there are four blocks of the same beds in this plan. That is on the principle on which Sir Joseph Paxton proceeded with the Crystal Palace. First of all, he hit on making one complete square or block of a house for Water Lilies, for the Duke of Devonshire; then it struck him, how easy it would be to extend this block system, east and west, or north and south, or in all directions. All after that was but a question of money. The circular part, called the transepts, was merely to break the uniformity of a great many blocks when put together. That curved portion, or rather the curve system, was an old way of hothouse building with him, and with others before him. Regularity was, and is, the grand secret in the Crystal Palace, and from it to the one-bed system on the little piece of grass in front of the casement window, regularity evinces taste and adaptation of means to an end. If you had room for only one flower-bed, the situation

of that one bed ought to show that the owner of it was alive to the beauty of regularity.

If you have room for one bed only, that bed must not be placed at one of the corners, or at one of the sides of your small piece of ground, and for this reason, that there is not a second bed to match it at the other corner, or side, so as to make the space equally divided, or regular. In the centre, however, this bed would be quite regular, because we cannot put two beds in the centre of a small piece of grass, and each of them be in the middle; therefore, single beds, or single blocks of similar beds, ought to stand in the centre of confined places; but, if more than one block is to be made, the very middle of the space must be avoided as a plague spot, for the reason just given.

There is an old story, in Scotland, about two daft bodies happening to meet of an evening at a farm house, and a bed for them was made in the barn for the night; but even pooridiots are not always harmless, as people say; for these two disputed about who should occupy the middle of the bed;

they fought, too, and also had torn the sheets, blankets, and all into two halves, and each of them took his half, and made a bed for himself. That was not a whit more daft than having the only two flower-beds on the centre of a small piece of grass, or a single bed, anywhere but in the middle.

The next step is, when there is room for only three beds, how are we to dispose of them? Nothing is more easy; if they had to stand as close as three in a bed, one of them would, and should, be in the middle, and the other two opposite each other; but, as pieces of ground that would admit of this disposition are very rare to be met with, we seldom see three beds anywhere, or, if so, only as a breach on regularity.

A four-sided piece of ground, if ever so small, will admit of four beds, or of five beds, according to the taste of the owner; and the two ways would be quite regular; one bed in the very centre, and one in each of the other. Here we have arrived at our aristocratic blocks, each of them are of five beds, a centre one and two side ones, the rest of the beds are mere accompaniments, and might be of half-a-dozen shapes, and still be in pairs, or double pairs, and so on.

It is not the shape of a bed, or a block of beds, that one ought to be so particular about, for there never was, and never shall be, a set rule for the shape of flower-beds. It is the disposal of the beds themselves, and the way the colours will tell best, that we have, all of us, to learn so much yet. Then we gardeners know very well, from our practice, that it is quite impossible to dispose of the colours to the best advantage unless the beds are so placed as to suit the extent of such and such a colour, in such and such places. All the world are not yet agreed as to the best disposal of the colours in flowers, but if they did so agree, without the beds and sizes of beds were laid down something like in due proportion to the colours and the heights of the plants that are fit to plant in a fine garden, the agreement would be of little practical value. Those who take their notions of the value or effect of colours from what the painters say of them, may or may not be all wrong, according to the knowledge of the said painter in flower colours. Even cut flowers may lead the best painter in the world astray as to the effect they would produce with the leaves, style of growth, and shade of the living plants. Practice alone will ever make a good arranger of a flower-garden.

D. BEATON.

THE still unascertained fate of Sir John Franklin and his companions, and the exploring expeditions still employed in endeavouring to ascertain more information concerning their route, and whereabouts, casts more even than the usual amount of interest over the Arctic Regions. We were glad, therefore, to avail ourselves of a recent opportunity of obtaining some authentic particulars of those latitudes, which are associated in our minds from childhood with no other ideas than endless snow and ice, and with days and nights alternately of months duration.

We especially sought for an account of the plants of that dreary region, and though we failed in attaining anything original, yet we were referred to a work from which we have derived what we required, and much more that is amusing and useful.

The publication referred to, is Dr. Sutherland's "Journal of a Voyage to Baffin's Bay and Barrow's Straits," in the years 1850 and 1851.

From this we learn that the land plants of the Arctic circle, though specimens of them, all in a growing state, can be contained in a box two feet square, yet amount in number to forty-five ascertained species. They are as follows:—

- Ranunculus frigidus Willd.* Assistance Bay.
- Papaver nudicaule L.* Assistance Bay.
- Cochlearia fenestralis Br.* Assistance Bay.
- Parrya arctica Br.* Assistance Bay.
- Cardamine hellsidifolia De.* Assistance Bay.
- Braya glabella Richardson.* Assistance Bay.
- Draba rupestris Br.* Assistance Bay.
- „ *glacialis Adams, var.* Assistance Bay.
- „ *alpina L.* Assistance Bay.
- Arenaria Rossii? Br.* Assistance Bay.
- „ *rubella Hook.* Assistance Bay.
- Cerastium alpinum L. var. glabatum.* Assistance Bay.
- Stellaria longipes Goldie.* Northumberland Inlet.*
- Lychuis apetala L.* Assistance Bay.
- Potentilla nana Lehm.* Berry Island and other islands in Davis' Straits.
- Dryas integrifolia L.* Assistance Bay, Berry Island, and adjacent islands.
- Cruciferae?*
- Epilobium latifolium L.* Northumberland Inlet.

* Known also by the name Hogarth Sound, which was given by Captain Parry, its original discoverer.

- Saxifraga pauciflora? Stev.* Bushnan Island.
- „ *oppositifolia L.* Assistance Bay, Berry Island.
- „ *nivalis L.* Assistance Bay.
- „ *cernua L.* Northumberland Inlet.
- „ *caespitosa L.* Assistance Bay.
- „ *flagellaris Willd.* Assistance Bay.
- „ *tricuspidata De.* Northumberland Inlet.
- „ *hirculus De.* Northumberland Inlet.
- Pyrola rotundifolia L.* Northumberland Inlet.
- Cassiope tetragona Don.* Bushnan Island.
- Vaccinium Vitis Idea L.* Bushnan Island.
- Arctostaphylos alpina Spr.* Northumberland Inlet.
- Polygonum viviparum L.* Assistance Bay.
- Oxyria reniformis L.* Assistance Bay.
- Empetrum nigrum L.* Northumberland Inlet.
- Vaccinium uliginosum L.* Northumberland Inlet.
- Salix cordifolia Parsh.* Assistance Bay.
- „ *arctica Pall.* Assistance Bay.
- Juncus biglumis L.* Assistance Bay.
- Carex Hepburnii Scott.* Berry Island.
- Luzula hyperborea Br.* Berry Island, Davis' Straits.
- Eriophorum polystachyum L.* Assistance Bay.
- Phippsia monandra Trin.* Assistance Bay.
- Alopecurus alpinus Sm.* Bushnan Island.
- Poa cenisia All.* Bushnan Island, Assistance Bay.
- Hierochloa alpina Wahl.* Bushnan Island.
- Luzula hyperborea Br.* Bushnan Island.
- Woodsia glabella Br.* Berry Island and other islands in Davis' Straits.

Of some of these plants we find the following particulars scattered through the volumes.

On the 29th of May, 1850, in the vicinity of Dark Head, Dr. Sutherland says:—

"Vegetation, as yet, had hardly made any advance, although snow-buntings and ptarmigan (*Tetrao saliceti*, and *Tetrao rupestris*) could be seen occasionally. The ptarmigan feeds upon the willow tops, and the snow-bunting upon the berries of the *Empetrum nigrum*, which are very abundant. I landed six years ago on the rugged coast, south of the Black River, in the bottom of South-east Bay, and found these berries so numerous in the month of May, that whole basketsful could have been collected; and, although they have been covered with snow during the whole winter and spring, and were so far liable to change of temperature, they did not seem to have suffered much from it, for they retained their sweet taste, and other properties peculiar to them in a fresh condition. It is very probable that the temperature had rarely been above the freezing point; otherwise, decomposition of their juices would soon have rendered them quite tasteless.

"A plant (*Pyrola media?*), known by the name 'bukolather' among the Danes, which is very abundant, is also very highly prized as an antiscorbutic; and when they have any fears of the approach of scurvy, it is collected in

basketsful, and a decoction or infusion made from it comes into general use."

Writing at Melville Bay, in the middle of August, Dr. Sutherland observes:—

"Vegetation was very far advanced. In some parts, especially the southern slopes, it was rather luxuriant. The *Andromeda tetragona* was beginning to fade; a specimen or two in bloom was obtained in a shaded spot. There was a whole array of Arctic plants. The well-known yellow Arctic poppy (*Papaver nudicaule*), one or two varieties of creeping willows, several grasses ten or twelve inches in length, the *Alopecurus alpinus*, and hosts of Cryptogamic forms could be recognised."

Gardening was not altogether neglected on board the ships even during their winter sojourn.

"Water-cresses and mustard were reared with great care, and they were very highly prized. Several stems were examined, and found to be four to five inches in length. The proportion of water which the young plants contained was so great, that one could hardly expect to derive great benefit from a few ounces of them every week. A portion was exposed to a temperature of 90° to 100°, until it ceased to lose weight by further exposure; the remainder, containing all the antiscorbutic and nutritious properties of the plant, amounted to 6·5 per cent., which was not nearly one-half the weight of the seed that had been used: the 93·5 which escaped, unfortunately happened to be water. I tried the same experiment several times with both mustard and cress, so that I might, if possible, receive favourable impressions with respect to the gardening; but the results were invariably the same, for the water which escaped by evaporation often exceeded 93 per cent. I could hardly credit that a plant grown in the dark, and destitute of every trace of green, containing such a large proportion of water, and almost insipid with the exception of the acrid principles of the seed and its essential oil, could possess virtues worthy of the slightest confidence. The young plants were less acrid than the seed, and the essential oil had almost all disappeared; their weight, too, was about half the weight of the seeds which produced them. Notwithstanding, its cultivation was encouraged and continued zealously, and the amusement and recreation it afforded proved of great value to those who devoted their attention to that department of horticulture."

"The Expedition was most munificently supplied with preserved vegetables, which still remained as fresh as when they were put into the tins. The allowance of them that was served out proved most ample at all times, and no one seemed to have any 'longing' for succulent vegetable food. The time, however, for this 'longing' was only approaching; for, up to this time, we had the use of fresh potatoes, which, be it observed, grew in 1849, passed through a summer and a winter in the Arctic Regions, in addition to one winter in the climate that produced them, and still retained their nutritious properties unchanged. They always deserved and got the preference, and now, that we had just used the last of them at dinner, we should have felt glad to have transferred the high esteem that had attached to them in the fresh state, to the patent preserved potato of Edwards; this, however, we could not do, in the presence of succulent carrots and turnips. The fresh potatoes sometimes became frozen, and, if they were permitted to thaw without being used immediately, fermentation commenced and in a very short time they became quite sweet: if, however, they were put into the vessel to be boiled, without first being thawed in cold water, they invariably became quite tough, so that they might be boiled into shreds, without removing the fibrous structure which they seemed to have assumed. A remark was made to the cabin steward, on one occasion, that the potatoes were not sufficiently boiled; his reply was, that they had been kept in boiling water for three hours. This reminded us of what Mr. Darwin observed in the lofty Andes, when his guides were blaming the new pot for not boiling the potatoes; the true cause being the lowering of the boiling point of water, from the immense height which they had attained, but of this they had no conception."

In our last, we gave it as our opinion that, in all probability, the *Frame Peas* will, in time, be discontinued as garden varieties; and that they will ultimately occupy much the same position that the *Charlton* does now. Every year confirms us more and more in that opinion, as we find new varieties introduced, rivalling them in earliness, and far surpassing them in excellence. Those which we are now about to describe sufficiently illustrate this fact; for, while they come into use almost, if not quite, as soon as the *Frames*, they are possessed of that peculiarly tender and rich flavour which is characteristic of the *Marrows*. Seeing, therefore, that we can have a sufficient supply furnished by those earliest varieties, such as *Sangster's Number One*, and *Warner's Emperor*, till the rich marrowy crops of *Nonpareil*, *Ringwood*, and *Paradise* are ready, of what use are the dry and mealy *Frames*, which come in at the same time?

FAIRBEARD'S NONPAREIL.

I am not very well prepared with a report of the comparative earliness of this variety, as I did not receive it

till some time after the others were sown, and I did not meet with it in the sample grounds of those members of the trade who so kindly afforded me that advantage; I consequently had no opportunity of comparing it with others. But it is said to be earlier than *Champion of England*, and as early as the *Frames*, and, from what I have seen of it, I have no reason to doubt this statement. Of this I am quite certain; it is a most valuable pea, and belongs to the class of sweet, wrinkled varieties, known as *Knight's Marrows*—in fact, a *Knight's Marrow* as early as the *Frames*!

The plant produces a branching stem, from three-and-a-half to four feet high, with a habit of growth and vigour similar to the *Double Blossomed Frame*. The pods are from two-inches-and-three-quarters to three-inches-and-a-quarter long, half-an-inch broad, somewhat curved, and terminated abruptly at the end. They are very full and plump, but do not become thick-backed and fleshy as they ripen, as the *Frames* do; and they contain from six to eight peas, which are close together, and very much compressed, being nine-twentieths-of-an-inch long, seven-twentieths broad, and six-twentieths thick; and of that very sweet flavour which is peculiar to the *Knight's Marrows*. The ripe seed is small and wrinkled, and of the same colour as the other white wrinkled peas.

This variety was raised by Mr. William Fairheard, of Green Street, near Sittingbourne, who also raised the *Champion of England*; and it may now be obtained through any respectable seedsman.

RINGWOOD MARROW.

Synonymes:—*Beck's Marrow*; *Flanagan's Pea*.

This is a very valuable pea, and another rival of the *Frames*. It produces a very large, well-filled pod, and is a most abundant bearer; but it has a peculiarity, which, by some, is considered an objection, from the pod being white instead of green, and presenting, when only fully grown, the appearance of over-maturity. This objection, however, is chiefly taken by those who grow it for markets, and who find a difficulty in convincing their customers, that notwithstanding the pod being white it is still in its highest perfection. So far from being soon out of season, the *Ringwood Marrow* retains its tender and marrowy character longer than many other varieties; and I trust, from the statement I have now made, and the extensive publicity which it will have, that any prejudice which may exist regarding the character of this excellent variety will be as generally dispelled. As regards earliness, I found it not more than two days behind the *Frames*; and, in every other respect, far superior to them.

Plant with a moderately vigorous habit of growth, producing a stem which is three-and-a-half to four feet high, and always simple, except in wet seasons, when it makes a second growth by throwing out shoots from near the ground. The lowest pods are within about a foot of the ground, and are produced at every joint, even to the extremity, the whole number on each plant being from ten to twelve. The pods are single and in pairs, in about equal proportions, from three to three-and-a-half-inches long, and six-tenths-of-an-inch wide, slightly curved and waved on the upper margin, and terminated rather abruptly at the point. As they ripen, they become thick and fleshy, with a rough, pitted, and shrivelled surface. They contain from six to seven large peas, which are roundish and not compressed, about nine-tenths-of-an-inch long, seven-tenths wide, and the same in thickness. The ripe seed is white.

The *Ringwood Marrow* was sown on the 5th of April, bloomed on the 10th of June, and was ready to be gathered on the 9th of July. It is far superior to *Shilling's Grotto*, both in earliness and filling.

There is a variety called LINCOLN GREEN, which possesses all the properties of the *Ringwood Marrow*, without the objectionable white pod, at least, so I am informed, but I cannot speak of it from my own experience, for the sample which I grew was late sown, and suffered so much by the attacks of the "*Dolphiu*" (*Aphis*), that it did not come to maturity. T. H.

(To be continued.)

HAVING given prominence to the statement by one correspondent, A. B. (page 354), of a mode of making cheap bread, which that correspondent declares she had "tried," and shewn the results to her "own labourers," we feel bound to give equal prominence to the following counter-statement, and shall be glad if A. B. can justify what she communicated.

With respect to the addition of Potatoes to flour made into bread, they render it less cake-like than Rice makes it, but, to us, it appears quite as palatable, and causes the bread to continue moist for a much longer time.

"I take the liberty of adverting to the receipt for cheap bread, introduced into the leader of your journal of the 9th instant, where you have been induced, upon the statement of a correspondent, to give further publicity to an error which had previously gone the round of the provincial, and many of the metropolitan newspapers. The fact of its being an error, you may, in one moment, convince yourself, by adding together the weight of all the ingredients your correspondent directs to be used, and you will at once see the impossibility of the result stated, unless we are again living in the age of miracles, and to those having faith an increase in the quantity of their Staff of Life (during the process of baking) is vouchsafed. If the bread made with $1\frac{1}{2}$ lb. of rice increased to the weight quoted, it could only be, of course, by the absorption of a much larger quantity of water than is allowed in the receipt given, and from which there would be no nourishment derived; but it is not even so, for I have repeatedly tried it, most carefully weighing every ingredient before mixing, afterwards the dough, and then the bread, and the result has always been that the increase in weight, over and above what the 14 lbs. of flour would have yielded, has been but a $\frac{1}{2}$ lb. more than the actual weight of the rice added, viz., 2 lbs., the rice added having been $1\frac{1}{2}$ lbs. The bread thus made is very nice eating, but to reduce the rice to pulp is a great deal of trouble, occupies a great deal of time, and requires a considerable amount of firing; these things taken into consideration, making the bread dearer, instead of cheaper than wheaten-flour bread.

"I have also tried the addition of Potatoes, and find the weight of the bread increased only to the weight of potatoes added; and certainly not so nice as by the addition of rice. 14 lbs. of good wheaten flour will absorb $7\frac{1}{2}$ lbs. of water, which, with $\frac{1}{2}$ lb. of yeast, makes 22 lbs. of dough, losing exactly 2 lbs. in baking; therefore, yielding 20 lbs. of bread, and making an increase of 6 lbs. (by the absorption and retention of water) upon the 14 lbs. of flour used, which is a much greater increase than can be obtained by employing any other ingredient, besides being purer, and far more nourishing, therefore cheaper, and in every respect the most desirable. If you add together the weight of your correspondent's ingredients, viz.,

Flour.....	14 lbs.
Rice.....	$1\frac{1}{2}$
Three quarts of water..	$7\frac{1}{2}$
Sufficient yeast.....	$\frac{1}{2}$

$23\frac{1}{2}$ lbs. of dough is the result. Allowing this to lose only 2 lbs. by baking (viz., the same as the 14 lbs. of flour dough), it will only yield $21\frac{1}{2}$ lbs. of bread. Now, there is no disputing figures, therefore I repeat that it is utterly impossible that $23\frac{1}{2}$ lbs. of materials can, by baking, (*without Divine interposition*), become converted into 30 lbs. of bread; and the publication of such statements are sure to produce either disappointment (more especially to the poor, who are not likely to enter philosophically into the subject, and discover the fallacy of the statement by calculation), or distrust, by creating doubts of the baker's honesty, to whose even the bread may be sent.

"To spare you the trouble of answering my query (addressed to you by note last week), concerning Messrs. Beck and Henderson's whereabouts, I write to inform you, that, after much trouble, I this day found their house of business,

but upon making application for some seed of the Pea, *Beck's Gem*, you spoke so highly of, in your Journal of the 2nd instant, I was informed that they had none except for their regular customers. Will you kindly inform your readers of this fact, and thereby spare many a fruitless journey.

"JOHN DENNY, *Stoke Newington.*"

POTATO CULTURE—SUGGESTIONS.

The present high price of this universal favourite, notwithstanding the great deterioration in quality, as compared with the Potatoes of a score years since, proves that the public still cling to it with as much tenacity as ever; although such immense losses have accrued to cultivators as would have driven any other root out of cultivation. We may, therefore, expect an enormous breadth under culture again this year; and I take it for granted, that practical hints from observant and experienced cultivators will be well received by our numerous readers.

A few years since, soon after the disease broke out, the press teemed with nostrums, recipes, and advice—the latter certainly of the most dogmatical character; and the public, fairly swamped with mere opinions, at last turned from the subject with disgust. The great misfortune was, that the bulk of all this gratuitous advice was given by persons whose chief qualification for the matter was an extreme partiality for this root, especially when accompanied by good old English roast beef. As our country farmers say, there was too much of the "fire-side ploughing;" and culture of this kind is not always of the most profitable. I take it for granted, that after all the visionary speculations that have been offered as the ground-work for future operations, the best way to deal with the question is to take warning from past facts, and to leave hypothesis to the mere experimenter.

One great fact, and that, on the face of the question, is this: that luxuriance of growth, so far from being an alleviator, is a promoter of the disease. This is so well established, that I will venture to affirm ninety out of a hundred of *really experienced and practical men* will readily assent to it. The next point established is, that late growth offers no chance of amelioration, but directly the reverse. Here, again, I have no fear of being left in a minority as to the opinion. These, then, are, I think, the two chief features of the question on which, for the present, to base our practice; other collateral points there are to which I will just advert, but they hold a decidedly subordinate position. Such being taken for granted, we may as well see for a moment how the two admitted evils are produced.

To say that manurial matters produce luxuriance is a mere truism—every schoolboy knows that; but, does nothing else contribute to it? Here is the rub! A man, holding opinions that rich manures prove prejudicial, may plant a plot in an old kitchen-garden, and fancy, that because he has added no *fresh manure* he cannot have erred in that respect; but this is most fallacious, and thousands annually thus mistake their course. I have known many a plot in a kitchen-garden much richer after a scouring crop, than the manured land of the farmer; at least, if not in manures, in the remains of former applications, or in that dark material termed humus, and which we gardeners find highly contributory to rampant growth.

Setting aside the question of manures for a moment—Is there nothing in cultural operations having a tendency to produce the undesirable condition of a gross plant?—Yes; deep digging; and this is unluckily favourable to late as well as rampant growths. Those who have long known me as a staunch advocate for deep digging, trenching, and such-like high cultural

operations, may think, in an off-hand way, that I "blow hot and cold."—Not so, however. When deep digging, manuring, &c., are found to be inimical to the welfare of any given crop, I, for one, am content to throw them overboard, although things of immense importance in themselves; in order to be better able to buffet the waves and avoid shoals and rocks. But I will quote a case which occurred with me last year. Having a desire to grow a liberal quantity of the *Ash-leaved Kidney*, SPECIALLY FOR SEED, an annual practice with me, I selected one of the poorest plots in the kitchen-garden; the previous crop had been the Red Beet, for which ground had been trenched; in doing so, about three inches of subsoil had been brought up, a usual practice with me. The ground was unmanured for the Beet previous, and, of course, unmanured for the Kidney; and, I will now add, UNBUD!

The ground was marked out in beds of about three to four feet—what our Cheshire farmers call "butts"—a corruption, doubtless, of "bouts." The Kidneys were set on the solid ground, exceedingly thick, in order to make them small and genteel; for we old Kidney Potato growers know full well that too high culture forces the Kidney to "run out," that is to say, to lose the handsome form for which it is in part so much esteemed, and to become dumpy and irregular.

The Kidneys, planted whole, of course, were about six inches square apart, every little fellow selected for shape, and set on end; they then had a slight dressing of old manure, delivered by hand from a basket, strewed over them; and next a coating of pulverised soil, about two inches in thickness. Nothing more was done until they were just bursting through the soil, with a crop of young weeds, when another two inches of pulverised soil was spread over them, thus "killing two birds, &c." This latter is the ordinary "butt culture" practice in Cheshire.

I have now to add, that the crop was enormous for the space occupied, I think nearly double that of some treated in higher style, and, as I expected, the majority of them were adopted for seed to plant whole, for it is nonsense to plant Kidneys whole nearly as big as a flounder, with the idea of having a superior crop; this is, indeed, a waste.

It may now be naturally expected that I should show how this deep digging may prove prejudicial to Potatoes in their present position; but in doing so, I must beg to qualify such remarks by observing, that I by no means affirm that deep digging is to be avoided in all cases. I am simply speaking of old tilled or dug soils, rich in the remains of former manures. Deep digging, of course, encourages deep rooting; deep roots are often at work when shallow ones are idle; and the system of the plant is, of course, thereby kept distended with invigorating fluids, which, as a matter of course, not only render the plant more gross, but, from the mere annual up to the huge Oak, through the various intermediate grades, sustains a lively circulation for a longer and later period in defiance of temporary droughts and other vicissitudes to which plants with mere surface fibres were ever liable.

Everybody knows, who has paid close attention to the character of the disease under varying conditions, that it assumes at least two distinct phases after a certain period; and here I would not defer the question to those possessing small suburban gardens, but to those whose lot is cast amongst thousands of broad acres, and whose locality is known as a Potato district. In such quarters, I have seen, repeatedly, extensive fields adjoining each other, and of precisely a similar staple of soil, the one covered with a moist and rotten blackness, the other dried up to mere sticks. And how is this? Simply because the one field produced a gross, or highly cultivated plant, the other a lean one, through the mere

inability, perhaps, of the farmer to provide as much manure for it as he would desire; and thus through a comparative poverty forced to befriend himself.

It will, doubtless, be remembered, that some weeks since I pointed to the immense success that a neighbour of mine has had who has grown annually a score or two acres, and that, too, on a tract of land that everybody despised, as it were, previously; it being what is termed "ploughed out;" that is to say, so hard-worked and ill-used as to require much handling to get it in temper again. I then stated, that as he kept no stock he was driven to the use of guano, and to this must be attributed, in the main, his success. And I here advise what I certainly shall practise, that where manure *must be used* it be very old, such as is calculated to spend its little remaining strength in a short period; indeed, if it were possible, I would prevent its being of any advantage to the plant after the beginning of July. With this view of things, I shall immediately prepare a compost to go in drills, or to be sown over beds just before covering the Potatoes. This compost will be composed of old, dry and powdery manure, much soot, and a little good guano, with perhaps a pinch of salt; and this, well mixed, I shall sow by hand from baskets. In the event of the soil being in tolerable heart, without manure at planting time, I shall, in the case of the beds or "butts" before described, add quick-lime to the same compost, and dress the surface of the bed or "butt" just as the Potatoe is breaking ground, and immediately soil it all over to prevent dissipation and to destroy weeds.

To make the young sprouts into a stout plant in a very short period after they break the ground, and that with such extra assistance as will desert them as soon as they are a good plant, is my policy; and the rest I leave to the atmosphere and the rains.

But mind, this by no means involves earlier planting than other folks; the planting question has nothing to do with it. Let people plant when they will, I hold it a maxim that Potatoes to be relied on for ordinary field or garden crops should not be allowed to expose their heads unprotected until the third week in May; but I would so manage them that they shall have done much work underground, like the mole, before they appear.

I would here caution the inexperienced against deep planting, especially for crops required early; but even later kinds love not to be buried deep. Let those who would prove this just try a few rows of early Potatoes side by side. Let them plant one lot about seven inches in depth, and the other about three, and I will engage that the latter will be ready for use nearly a fortnight before the deep-planted ones. Moreover, early crops are best without *after applications* of soil, if it can be dispensed with. I have known a frame of Potatoes retarded a fortnight or more by an ill-judged application of surface-dressing when they were six inches or more in height, and no wonder, either. Persons thus over officious do not consider, that in so doing they interpose a cool and fresh body, somewhat nonconducting, between the generally warmed medium the roots are in and the atmosphere, and that such interposition must lower the temperature where the roots are situate by perhaps five degrees; of this fact I am persuaded, having well proved it.

In taking leave of the Potato for a little while, I would impress on our readers the common-sense proceeding of procuring as good seed as possible. It is all very well to say, in despair,—“It matters little about seed; I have known corrupted seed produce as good a crop as the very best.” This, although a fact in a few solitary cases, is what I call a most unphilosophical and cowardly conclusion. What! because anomalies exist in this case, as, indeed, they beset most matters, shall the mind of man, in a fit of mere childish impatience, in the most

gross and undistinguishing manner, rush on an impotent conclusion?

Our Sir Isaac Newtons, our Dr. Johnsons, our Paleys, were not men of this metal; they were made of "sterner stuff." As well might a cattle breeder forswear all right of pedigree through "blood," because, forsooth, he made a first-rate "hit" from a most ordinary source. I doubt not, myself, that the Potato will one day be restored to us in its original strength; but bad seeding, bad breeding, and conceited modes of culture, based on no real principles, certainly do not offer the best chances of such a desirable consummation.

R. ERRINGTON.

TREES AND SHRUBS.

HOLLIES.

THERE are above a dozen of the Common Holly with green leaves, and above a score of Variegated Hollies. Some of the green kinds are named variously, from the size or shape, or from prickles or no prickles, from the thickness or thinness of the leaves, and also from the Holly-berries being yellow, black, or white—and out of these one might pick up six or seven very distinct sorts; but there is no right or regular system of names by which they can be asked for that I am aware of. It is the same with the Variegated Hollies—one must see them to make a selection of sorts. Silver, Golden, and Hedgehog Hollies give but a very faint idea of this class; and so do the best Nursery catalogues. Nothing short of seeing a good collection in the large nurseries can enable one to make a selection of such plants. When one is going to buy in earnest—even one of our best country gardeners—he would know more, and learn more, in one hour, going over a large nursery, when the plants are all in leaf, than he could by reading about new trees and shrubs for a whole week, if he had nothing else to do. Besides the varieties, there are several new Hollies, and old ones, too, that ought to be in every good collection.

AMERICAN HOLLY (*Ilex opaca*).—A beautiful, low tree, which is used all over North America as we do the common Holly. *Laxiflora* is only a variety of *Opaca*, according to Nuttall.

MINORCA HOLLY (*Ilex balearica*).—A very distinct kind, which comes nearest to our common Holly, on which it is propagated by buds and grafts in the usual way.

DAHON HOLLY (*Ilex cassine*).—There are two very distinct Hollies, from America, which are often confounded under this name; one, with small leaves (*Ilex cassine*); and the other, with large, smooth leaves with hardly a prickle on (*Ilex dahoon*), and thought to be a greenhouse plant; but the two are equally hard, only that *cassine* ripens scarlet berries, and *dahoon* never does with us.

THE NARROW-LEAVED HOLLY (*Ilex angustifolia*, alias *myrtifolia*).—A very rare plant indeed; but a very beautiful and well-marked species, from North America. It prefers a low, damp situation, being naturally a swamp plant in Virginia and Georgia. It was also called *Ilex rosmarinifolia*, which gives a good idea of its appearance.

THE PERADO HOLLY (*Ilex Perado*).—This is the *Ilex Madagascensis* of some of our nurseries and some French collections. This is a Holly from Madeira, and is often kept in the greenhouse, but it is quite hardy. It has shining and nearly smooth leaves, and forms a close, dwarf, evergreen bush.

THE EMETIC HOLLY (*Ilex vomitoria*).—A scarce plant, from the sea-shore from Carolina to Florida. It is sometimes called the South Sea Tea and Cassiobery bush, in our gardens, also *ligustrifolia*.

ILEX LATIFOLIA, alias *laurifolia*.—A fine broad-leaved Holly, from Japan. Grafted on the common Holly, is quite hardy, and ought to be in every good collection, being the best of all the new Hollies.

ILEX DIPYRENA.—A beautiful Holly, recently from the North of India, but quite hardy.

ILEX LATISPINA.—A very marked species, with broad prickles set in a zig-zag way on the leaf; quite hardy, and well worth having among new plants.

ILEX MICROCARPA.—Another very distinct species, with large, thick leaves without prickles, promising to make a large, handsome evergreen.

ILEX CORNUTA.—A very curious, new Holly, with long, fleshy leaves, having three formidable spines at the end of each.

ILEX FURCATA.—Another curious spined Holly of recent introduction, which promises to make a well-marked species; but all these new Hollies are so much sought for that only very small plants of them are sent out from the Nurseries. They are all in the garden at Bank Grove, near Kingston, and do not seem the least touched by the frost. I see they increase some of them by cuttings, as well as by grafting on the common Holly.

ILEX MAGELLANICA.—I have only seen but very small pot-plants of this either, but it seems a very distinct sort. These, and a few other sorts, are merely nursery names about London, but I do not know the authorities or the parties who gave these names. The plants, however, are becoming very fashionable, like the evergreen Berberies and Conifers; as also are the new Evergreen Oaks, of which there are several very interesting ones in the Nurseries. One, called

QUERCUS ILES ZAN, took my fancy very much at Bank Grove, the leaves being nearly as large as those of the common Oak.

QUERCUS AGRIFOLIA.—The Evergreen Oak of California is a very remarkable plant, having smooth leaves when quite young, but as the plant gets older the leaves turn as prickly as those of a Holly. "The long, narrow acorns, almost conical, are a remarkable feature in the species." Nuttall, the American botanist, who knew this Oak in California, says, "As a hedge it would form a very close shelter, and the leaves, evergreen and nearly as prickly as a Holly, would render it almost impervious to most animals." The wood is of no account.

QUERCUS SCLEROPHYLLA (Hard-leaved Oak).—A new one from China, a very marked evergreen species. It was sent over by Mr. Fortune, in 1850, and being quite hardy, it promises to make a handsome addition to our large evergreens.

QUERCUS INVERSA.—Another Evergreen Oak, from the north of India, by Mr. Fortune, quite different from any we had before, but in habit somewhat like our old evergreen Oak. These China Oaks are sold by the Messrs. Standish and Noble, of Bagshot, but, of course, any nurseryman in the kingdom could get them for any gentleman in the neighbourhood, and that is always the best and cheapest way to go to work. If I wanted a new plant from Dublin, or Glasgow, or Edinburgh, I would order Mr. Jackson, of Kingston, to get it for me. Of course, if I did not deal with him I could not ask him to take the trouble, and even then I would give him his own time.

OAKS IN GENERAL.

The kinds or varieties of Oaks, in all parts of the world, are just as numerous as the Geraniums, and as easily multiplied by seeds; they also run into sections, as distinct from one another as the sections of Geraniums. The *Ilex*, or Evergreen Oak section, and the Willow Oak (*Phellos*) section, are the most sought after for pleasure grounds and large gardens, and there is hardly an end to the variations they run into from the

acorn. The *Lucomb Oak* is the finest tree that ever originated in England. If people would but manage the different kinds of *Ilex*, or Evergreen Oak, so as to get them up like the Lucomb, or the Turkey Oak, some of the broad-leaved sorts of *Ilex* would make more handsome heads than even the Lucomb Oak. There are no plants in England worse managed than the old Evergreen Oaks, and that principally for not knowing how to prune them when they are young. They should never have but one leader; and when they come bush-headed from the first, heading them back to near the ground is the easiest way to manage them.

SYMPLOCOS JAPONICA.

Quite a new evergreen from Japan, with leaves like the Sweet Bay, and growing as tall at home as the Bay does here; the flowers are of no account. They have a *Symplocos* (*tinctoria*) in the southern States of North America, called the Sweet Leaf, which they use for dyeing yellow; and the Japanese use this one for decorating their idols, as we use the Christmas Holly. This promises to be a very beautiful evergreen, and to be as hardy as the *Cryptomeria*. Mr. Fortune sent it, in 1850, to the Bagshot collection of his novelties.

VIBURNUM PLICATUM.

A large, handsome-flowering, deciduous shrub from the north of China, sent home by Mr. Fortune, with round balls of snow-white flowers, after the manner of the Guelder Rose, very much cultivated in the best gardens in China. It comes nearest to an old American *Viburnum*, called *dentatum*; and I think, to make the best of it in this country, it ought to be grafted on *dentatum*, which will grow in any good garden soil, while *plicatum* refuses to grow well in many places.

VIBURNUM MACROCEPHALUM.—Another of Mr. Fortune's plants, from the north of China, where it seems to be as great a favourite as the Camellia. He says, there is a plant of it, in the island of Chusan, 20 feet high, and flowers all over, down to the ground, something like large heads of Hydrangea. I have seen this in flower in the gardens of the Horticultural Society, and I can safely say it is superior to the Hydrangea; but the heads are not so flat as in the Hydrangea, and the flowers are pure white. I have this fine thing in my own garden, but do what I will I cannot make anything of it; no frost seems to hurt it, and no soil agrees with it, as far as I can make out, and I see nothing for it but to graft it on some near relative—on *dentatum*, or *pubescens*, or some such allied plant; others must find it as difficult, also, or otherwise we should have had it at the May exhibitions among the very first.

MYRICA CALIFORNICA.

A sweet-leaved evergreen Gale, from California, by Hartweg to the Horticultural Society. This is a valuable evergreen, and is quite hardy; the first time I saw it was in-doors in a pot, and I mistook it for a broad-leaved Banksia, or something that way, which will give a tolerable idea of it to those who know these Banksias. I have also seen a plant of it loaded with seeds, which will make it cheap for a new plant.

DAPHNE FORTUNI.

A charming addition to our sweet-scented flowers, and belongs to the Mezereon section of the genus, coming into flower early in the spring and casting its leaves in the autumn. The flowers are much larger than those of Mezereon, and of a pale bluish-lilac. It has been ten years in England, but not grown half so much as it deserves.

EDGORTHIA CHRYSANTHA.

Nearly related to the Daphne; a deciduous shrub,

from Chusan, by Mr. Fortune. It requires a good, warm situation to flower well, but like the Yellow Jasmine (*nuliflora*) and the *Forsythia viridissima*, all from China, they answer much better as pot plants, to be protected while in flower, until such time as the plants are of a large specimen-size, when they will take care of themselves.

AZALEAS.

AZALEA OVATA.—Next to *Weigela rosea*, this is the finest-looking evergreen shrub on the hills of Chusan, according to Mr. Fortune, and the best of all he found in the east. It is quite a different thing from all our greenhouse Azaleas, being quite smooth in the leaves, and quite-hardy after it comes to a good size. It, however, as well as the Viburnums and the Roses which he introduced, do not get on with us, except in rare instances here and there.

AZALEA AMENA.—This is also a quite hardy, north-of-China plant, and most suitable for the front of a choice American bed. The flowers are of a light purple in the open air, and look as if one was within another, like the hose-in-hose Polyanthus, and the leaves are the smallest of all the race.

SPIRÆAS.

SPIRÆA LINDLEYANA.—As a standard, or for covering the north side of a house, or any other cold wall, this is invaluable, but as a bush it is only a fiddlestick, getting soon so confused that you can do nothing with it. It can be made standards of, exactly as they do standard Currants, first making cuttings, from which all the bottom eyes are taken; or, which is done much sooner, cut down a strong bush of it close to the ground, and make layers of the very strong, soft shoots which rise immediately; first cutting out the eyes from the part in the ground. Now is a very good time to cut one down, but it may be done all through the spring.

SPIRÆA ARLEFOLIA.—Ought to be in every garden for its elegant plumes of white flowers all through the autumn.

SPIRÆA BELLA.—Another great favourite deserving a place in the choicest collection.

SPIRÆA CUNEIFOLIA, **S. LAXIFLORA**, **S. VACCINIFOLIA**, and **S. ROTUNDIFOLIA**, are all North Indian low shrubs, well deserving extensive cultivation; and **S. FISSA**, from Mexico, a tall, handsome bush, equally so.

SPIRÆA EXPANSA.—Also a North Indian plant, with flat heads of pinkish flowers, is very handsome.

SPIRÆA PUBESCENS.—A newer one, from Chusan, with little heads of white flowers, and not more than a small tufted bush.

SPIRÆA PRUNIFOLIA, with double white flowers, is also from China, and is highly prized already for its elegant spikes of crowded flowers—a real acquisition—like a double-white Hawthorn.

SPIRÆA DOUGLASH.—A fine, late autumn-flowering one, with large heads of white flowers, in August and September.

SPIRÆA REEVESIANA.—Single and double flowers; the former is a graceful shrub; but naturally flowering very early in the spring it often fails with us, unless the wood is well ripened in the autumn. The double-flowering variety is said to be more free; but I never saw it. This last is quite a new shrub; as also one called *Spiræa callosa*, with nearly white flowers, but it is new to me.

SKIMMIA JAPONICA is a low evergreen, with scarlet berries in winter; quite new, and one of the best of the low, bushy evergreens. I have described it at length in a former volume.

DOUBLE CRIMSON PEACH, and the **Double white Peach**, both from Africa; ought to be in every select collection, particularly the crimson flowered one, on which the fruit comes in clusters together, but it is of no value.

D. BEATON.

TOBACCO—NICOTIANA.

THIS is a plant that generally arrests a considerable amount of attention among visitors, and a whole chain of queries are launched upon the cultivator, coming alike from the young *gent* who never before had any idea of the look of the plant from whence he obtains his box of mild Havannahs; from the tyro feeling his way amid the vexing questions of taxative and social economies; and from the farmer, with an eye to the main chance, who cannot for the life of him see why, since he has been forced to compete with all the world in corn-growing, he is not allowed free scope for an equal test of his abilities in the supplying his countrymen with *Tobacco*.

The general position for the Tobacco-plant would be a rich piece of a field, or the sheltered, well-manured, kitchen-garden; but the kind generally cultivated—*Nicotiana Tabacum*, the Virginian or Kentuckian variety, and *macrophylla*, a very large-leaved species or variety—make a noble appearance in front of a shrubbery, the large leaves being far more attractive than the heads of dumpy pink flowers. Then there are other species, that instead of mounting from five to seven feet in height generally rise no higher than from one-and-a-half to two-and-a-half feet; have nice, sweetish, white flowers, such as *undulata*, sometimes called *suavcolens*, *rotundifolia*, and *longiflora*, that are neither uninteresting when grown in a bed, nor when cultivated as specimens in pots. Though some of these latter, if favoured by greenhouse treatment, would become perennial, yet all, when grown out-of-doors, will be most successfully treated as rather tender half-hardy annuals.

The botanic name is commemorative of John Nicot, who sent seeds from Portugal to France about the middle of the sixteenth century. The common name is attributed by different persons to different sources—some contending that it is derived from Tobago, the most southerly of the Caribbean Islands; others alleging that it comes from Tabaco, a small island in the bay of Panama; while others assert it comes from Tabasco, a district bordering on the Bay of Campeachy, in the Gulf of Mexico. It is altogether a matter of no moment which of these places, or if any of them, was thus honoured in giving a popular name to this narcotic, that, in spite of the edicts of princes, is accompanying the footsteps of civilisation, and, unless kept under due moral and sanitary restraint, is calculated to do, ere long, for mankind generally, what opium has done for its votaries, and the fire-water for its worshippers. A fact of more importance is, that all these places are within the tropics, implying thus that a high temperature is necessary to bring the Tobacco-plant to the highest state of perfection. True, very fair Tobacco is produced in the south of Europe, and even as far north as Holland, and what are called splendid samples come from Kentucky and Virginia, yet even the best connoisseurs allow, that for an agreeable puff that waits them unconsciously amid the idealities of dream-land, there is nothing like a bit of real Havannah, at which place we know the temperature is not only tropical, but a dry, sunny atmosphere generally prevails, rains seldom appearing unless in July and August.

There is some difference of opinion as to the introduction of smoking into England, but it is generally supposed that Sir Walter Raleigh made it fashionable by his smoking parties at Islington, during the last decade of the sixteenth century. The practice—the virtue—or rather the vice—soon became so extended, that the princes of Christendom, with unerring infallibility, in the shape of the Pope at their head, promulgated shoals of awful penalties against the user of Tobacco, which proved just as effectual as the proclamation of the Emperor of China against his subjects using

Opium. Finding such edicts of no avail, they showed their worldly wisdom in filling their coffers with a heavy tax on the growth or importation of an article, the using of which they were powerless to prohibit—a tax that in one shape or another meets the tobacco consumer go almost where he will in civilised society. This is not the place to inquire into the propriety of a government taxing heavily any commodity, the use of which would foster the virtues, minister to the necessities, or encourage the vices of its people; but while a revenue must be collected, most disinterested persons would admit that that revenue should be raised from luxuries rather than necessities. In this former category I would place Tobacco. True, many a hard-working man, as well as they who would find it an impossibility to separate between the puffing of a cigar and an assumed gentility, look upon the “weed” as an indispensable *necessary*; and often have I heard a working man, when remonstrated with about his grumbling as to his circumstances, and yet wasting so much per week on the soothing herb, forcibly declare, that he would give up his dinner before he gave up his pipe, though I believe it was but seldom that dining was neglected if it could be avoided. Thus *both* had to be paid for, and the grumbling went on; the poor man forgetting that the chief means for his attaining comfort and respectability consist in striving, when young and healthy, for the means of securing some of the comforts and luxuries of existence, and then, by denying himself of their frequent use, obtain, by that honourable self-denial, the means of commanding comparative independence of character and position.

Since corn has got up to something bordering upon famine price, I have heard less grumbling, from my farmer friends, that they are not allowed to grow Tobacco duty free, when they must compete with the world in corn. To my understanding, this would merely be *protection* over again. Our farmers may grow Tobacco now, against the foreigner, as much as they please; but they know their only chance of success would be in not being taxed as the foreigner is. The lover of Tobacco, in any of its shapes, would only obtain then an inferior article, at but little diminution in price. Some farmers, last year, endeavoured to demonstrate to me, that on good soils in England they could raise a heavy crop of Tobacco as easily as a crop of turnips; but to this, considering the natural tenderness of the plant, I wholly demur. That a crop should thus be obtained, by sowing in May, I do not deny; for I have often seen strongish plants, the seeds of which had been self-sown and survived the winter. I have also seen strong patches of Tobacco far north of the Forth; but there, in my own practice, and when cultivated by others, with the greatest success, in Meath and Wexford, in Ireland, the plants were treated as half-hardy or tender annuals: the seed being sown in hotbeds during the middle or end of March, pricked out into another bed, where they could be protected, or placed separately in pots, and then transferred to rich, well-aired soil after the middle of May; shading them from the sun until the roots take hold, by means of pots, an evergreen branch, or a little clean, loose litter, placed thin, and fastened on each side with a clot of earth. By these means our summers are prolonged; and fine specimens, as respects growth, may be expected. But it should not be forgotten that it is a very exhausting crop, and requires very richly-manured land.

I hardly know what is the state of the law now. A lawyer told me, two years ago, that I was liable to a penalty for a piece which I had then growing—even though I applied it entirely to the destroying of insects. I suspect that Government would not interfere with a largish plot in a garden. With the first promulgation of the taxing of the article, any one was

allowed to grow half a pole for medical purposes; and, therefore, every cottager, who can conscientiously look upon Tobacco as a medicine, may comfortably grow that quantity; and then, by means of a slight hotbed, or raising his seedlings near his kitchen fire, and moving them to the window—much in the same way as mentioned the other week for *Pelargonium* seeds—by careful tending and curing, he may secure from three to four pounds of very passable Tobacco.

The mode of sowing has already been referred to. As the seed is small it should be thinly covered. Whatever means are at hand for getting good plants by the middle of May should be adopted, as the quantity, if not the quality, will greatly depend on this. Towards the end of May, the ground having previously been well dunged, and aired, and pulverised, turn these good plants out about eighteen inches apart. I used to put them about sixteen inches in the row, and the rows three feet from each other. If taken from a box or bed a little shading was given at first. When young seedlings, as soon as they can be easily handled, are pricked out in beds or boxes, in lightish soil, and with very rotten dung beneath, giving them a square of three inches, from plant to plant, or even a little less, they can be raised with nice balls, by means of a trowel, and will soon take hold of the garden soil, and thus want but little shading. They must be watered every day in sunny weather for some time, using water well warmed, so as to increase the temperature of the soil as warm as new milk. At this tender stage the plants are exposed to various enemies; and a friend of ours has often told me that just the best sign of how good a thing Tobacco is. Be this as it may, the wire-worm and the millipede will go some distance for a nibble, and traps of sliced Turnips, Carrots, &c., must be inserted in the soil as enticing guardians. Mr. Slug, however, is the worst to get rid of; brewers' grains will prove a more attractive narcotic for him than even the Tobacco, and dozing on heaps of these he may be caught napping in a morning. Failing that, a little soot and lime *often* sprinkled round the plants is a good remedy. Surface-stirring of the ground with the hoe, but, better still, with the points of a fork, will cause them to flit their quarters, and be of great service to the plants. Plenty of waterings will be eagerly drunk in in dry, warm weather. If there is abundance of manure in the ground, a little quick-lime in the water will render the manure more soluble for the plants. If the ground is not well manured, it should be applied with the waterings, in a liquid state; any kind being serviceable if not given too strong. By the time the plants have made from a dozen to eighteen leaves, the stem should be stopped, otherwise much of the strength of the plant would be thrown into the head of flowers and seeds. For garden use, two or three pods of seed will furnish an ample supply. After this stopping the leaves will increase rapidly in size. The check thus given to the ascending growth will cause laterals to push freely from the axils of the leaves, but these must be all carefully picked out as soon as they appear; in fact, the whole strength of the plant must be thrown into the large, massive foliage. The plants will be injured by a very small amount of frost, and, therefore, it is desirable to harvest the crop by the middle of September, or not long after; and, if all has gone well, the lower leaves will begin to show signs of arriving at maturity by that period.

In gathering, or rather in drying and preserving the crop, much care is necessary, so much so, indeed, that though it might be economical, so far as securing a source for destroying the green fly, it could never be economically managed, on a small scale, for securing the cottager four or five pounds of tobacco for smoking, if all the labour was to be accounted for. I have gathered the crop all at once, by pulling-up, or cutting.

down the plants close to the ground; or by going over the plants at several times, and making several gatherings of the larger leaves; and though by the last method more produce was obtained, and, therefore, the best means to follow when the plant was cultivated largely, yet, on a small scale, the gain did not counter-balance the additional trouble. In either case, after being gathered the leaves should have no more sun than was sufficient to soften them, so that they were so pliable as to be easily handled without breaking. In this state they should be stripped from the plants, strung together in strings through their midribs, so close as not to touch, and then hung up in a shady, airy place, under cover. The eaves of old-fashioned cottages, garrets, and sheds, through which there is a circulation of air, would answer admirably. When well-dried, they are taken down, packed neatly in a heap, the stem-ends inwards, and covered with a cloth, or a little hay, until they begin to ferment, taking care that the heat does not much exceed 100°, allowing them to remain several days, and then taking them out and drying, and submitting again to a similar process, by which time the midribs will be quite pliable. When again almost thoroughly dried they must be packed regularly and firmly in boxes and air excluded. If any thing like mould appear the leaves should be dried again, and then packed. Those who are interested in knowing how these leaves, after various washings and herbs added, are changed into the tobacco and snuff of our shops, would do well to visit a tobacco manufactory.

There is a mode somewhat simpler that used to be adopted by the Horticultural Society, and if a nice brown colour in the leaf, if a rather pleasant smell, if the highest commendations from professed judges, who used to *come out* with their *splendid* Havannahs of home growth, be any criterion, then the outline of the system is worth mentioning, and, where circumstances admit, worth imitating. The plants were all taken up in September, and taken at once to a Mushroom-house, where they were suspended against the walls, and by strings all over the house. The house was then shut, and by means of fire-heat a temperature of 70° was maintained for four or five days, until all the leaves were yellow. The heat was then raised to 75°, and the leaves, with the exception of the midribs, became of a fine brown colour, the midribs being yet green and succulent. The heat was then increased to between 80° and 90°, and in five days the midribs were dry and brittle. The leaves being curled and very brittle, heat was discontinued, and the floor of the house watered several times, until, by its evaporation, the leaves were again soft and pliable, when they were stripped from their stalks, laid out evenly in a heap, well pressed, and then packed in a tub. In a fortnight, a little mould made its appearance, when they were re-hung in the house, gradually re-dried, and the floor more gently watered than before, and were re-packed again and kept in a good state. Many years have passed since I saw some of this Tobacco, and great changes have taken place since then, but as a home-cured article it was very superior, and no doubt answered the designed purpose well.

If carefully used, such home-grown Tobacco may be safely employed for the extirpation of insects; but if allowed to burn too fast, by using it in a dry state, or without abundance of a damp covering, such as moss, it will do more harm to plants near it than to the insects. I have seen some used that had been half-rotten in the sweating process; I have seen others that had been dried by being hung in an open shed, and its good properties thus dissipated: both doing great injury to plants. I recollect smelking a peach-house, when an apprentice, with this latter material, blowing away with might and main at a hole in the side of a pot filled with it, until the foreman, standing at the outside of

the door, should pronounce the house full enough, and afford me an exit from such a Pandemonium. In three days almost every young Peach had tumbled. Unless, therefore, some care is taken in the drying and the burning, I would advise amateurs to stick to the manufactured slag, so far as their plants are concerned. The most of the so-called Tobacco-paper is worse than home-grown Tobacco, however badly cured. In large places, the latter, with moderate attention given to it, used alone, or mixed with the manufactured, will be found economical. R. FISH.

THE ANTIRRHINUM.

THERE are few flowers that have been so much improved by the skill and perseverance of the florist as the Antirrhinum. The species that has been hybridized and improved is named by the botanists *Antirrhinum majus*. It is a native of Britain, and is found on rocks and old walls in abundance. The generic, or family, or first-name, is derived from *anti*, like, and *rhin*, a snout,—flowers having the appearance of an animal's snout. The second, or specific name, *majus*, means the larger, to distinguish this species from the rest of the genus, but more especially from *A. meanthum*, the lesser-flowered. The varieties of this greater Snapdragon (the English name) are very numerous. A seed-bed will produce endless varieties; and this propensity to sport has been made use of by florists to improve the form, size, and colour of the progeny, and that, too, with considerable success; but there is still great improvement needed to render the varieties standards of perfection.

The Properties that are considered necessary to form a perfect flower of an Antirrhinum have not been defined by any florist, that I am aware of, excepting Mr. Glenny; and I hope he will excuse me if I transcribe his ideas on the subject, though I think, if Mr. Glenny himself had to write them over again, some of the points would (as I hope to see the flowers themselves) be better defined.

"Properties of a first-rate Antirrhinum:—

"1. The plant should be dwarf; the flowers abundant; the mouth wide, and the more the inner surface turns up to hide the tube the better.

"2. The tube should be clear and pure, if white, and if any other colour, it should be bright; and the mouth, and all the inner surface, should be of a different colour and texture (?), and form a contrast with the tube.

"3. The petal should lap over at the indentations, so as not to show them; the texture of the tube should be like wax, or enamel; the inside surface, which laps over, should be velvety.

"4. When the flower is striped or spotted, the marking should be well-defined in all its varieties (variations?); the colour should be dense, whatever that colour may be.

"5. The flowers should form spikes of six or seven blooms, close, but not in each other's way; and the footstalks should be strong and elastic, to keep them from hanging down close to the stem, which they will if the footstalks are weak."

The way that they should be shown requires some consideration. I am an advocate for all florists' flowers (that can be grown so successfully) to be shown in pots. The public then can judge more effectually of the appearance they would make in the borders of the flower-garden. We have seen that the Rose, the Pansey, and the Carnation can be grown and exhibited in pots with excellent effect, and I am certain the Antirrhinum can, also, quite as well be grown and exhibited in pots—thus showing the plant as well as the flower. This flower is

quite capable of being shown in classes; and they should be distinguished as follows:—

1. **SMOOTH.**—Such as have no spots or stripes.

2. **STRIPED.**—Such as are clearly striped; no spots to be allowed.

3. **SPOTTED.**—Such as have the whole flower spotted, though the tube may be allowed to be of a pure white, or any other colour, providing it be clear, bright, and distinct.

The following varieties prove that such a division into the above classes is practicable, even with such as we possess now.

SELFS.—*Saturne*, deep purple-crimson; *Sulphurea perfecta*, clear sulphur.

STRIPED.—*Flamingoe*, striped rose; *Hendersonii*, blush and red edge.

SPOTTED.—*Constance*, purple, and yellow throat, with white blotches; *Van Erchodt*, red-crimson, with yellow throat and white blotches.

I have thus, as I think, clearly made out, to the satisfaction of the unprejudiced reader, that the Antirrhinum is capable not only of being improved in its desirable properties, but also may be further improved as an exhibition flower, by being grown in pots, and exhibited in at least three classes, thus creating a greater interest to the grower, the exhibitor, and the visitors to such exhibitions where they are so shown. I do not, by any means, consider such distinctions frivolous, nor the raising of improved flowers useless. On the contrary, I am certain such pursuits tend to civilize and elevate the minds of such persons as may devote their leisure hours to such recreations. Every hour that can be honestly spent in the culture of flowers is, at least, innocently spent, and may, in many instances, be profitably so, even to the most devoted utilitarian, for whatever pursuit brings most cash into the purse is, with some minds, considered the most worthy of being followed. This, perhaps, I may say, sordid motive, influences sadly too many of the cultivators of such lovely things as flowers. Even such may have their passion gratified by raising seedling florist flowers; and, in Antirrhinums, especially, there is a wide field for speculation. Passionate lovers of new Antirrhinums will not grudge giving a good price for a really superior variety, and, therefore, even the utilitarian may be induced to try his hand at the game, though I hope many, many others will follow on in the same track merely for the love of the pursuit, independently of any profit there may be in the event. In my next paper I will endeavour to direct such in the way of success.

T. APPELBY.

(To be continued.)

STOVE FERNS.

(Continued from page 383.)

ELAPHAGLOSSUM SCLOPENDRIFOLIUM (Scelopendrium-leaved).—A Brazilian Fern, of great beauty. The barren fronds are more than a foot long, pale green, wavy at the edges, and of an oblong lance-shape. The stem of these leaves is about six inches long; the stems and margins of the fronds are covered with hair-like scales. Fertile fronds upright, nearly eighteen inches high, upon a stem of eight inches. Root-stock creeping, short, and scaly. Increased by division.

E. VILLOSUM (Shaggy).—A curious, handsome Fern, from the West Indies. The barren fronds are remarkable by being covered with long, shaggy hairs; they are of an oblong lance-shape, sharp pointed, and a foot long. Fertile frond narrow and short. Increased by its creeping root-stock.

FADYENIA.—A genus named in honour of Dr. Fadyen, who spent several years of his life in Jamaica. There

is only one species known, and a very curious little Fern it is. I have cultivated it for several years, and found it to grow best if the pot containing the plant was placed in a shallow pan of water in the Orchid house. Very little water was given to the soil in the pot. The plants grew strong and spread over the surface of the earth, completely covering it with their broad, sterile fronds, which frequently produced young plants at the ends of the fronds.

F. PROLIFERA (Fruitful).—A Jamaica Fern. The sterile fronds are simple, spreading horizontally, and frequently producing plants at the points; hence it is called proliferous. The fertile, or seed-bearing fronds are also simple, but stand upright in the centre of the plant, growing about five inches high, lance-shaped, narrower at the base, and blunt at the apex. The most remarkable character of the species is the seed-vessels. These are disposed alternately on each side of the midrib; they are very nearly the shape of a horse-shoe, with the margins thick and hairy, and are very large and conspicuous. Increased by the young plants produced at the ends of the sterile fronds. A very curious, interesting, small Fern that ought to be in every collection.

GONTOPHLEBIUM.—A genus of Ferns formed out of Polypodium by Mr. Prest, and so named from *gonia*, an angle, and *phlebia*, a vein—the veins forming angles on the underside of the fronds. The distinguishing characters of the genus consist in the angular position of the veins. The sori placed at the end of the vein, and these seed-vessels being round.

G. ALBO-PUNCTATUM (White-spotted).—A very distinct species, from the Brazils. Fronds two feet long, almost triangular, pinnate, having the upper surface spotted over with white scales. Leaflets undulated, and the upper ones without stems. Seed-vessels in one series. Root-stock scaly and creeping, by which it may be easily increased.

G. ARGUTUM (Sharp-cut).—A beautiful, rare Fern, from Nepaul. Fronds pinnate, of a lance-shape, with sharp-pointed leaflets, growing a foot-and-a-half high; stems pale brown, and shining; seed-vessels large in one series, and of yellowish colour. Increased by dividing the scaly, creeping rhizoma. A very elegant Fern, worthy of universal cultivation.

G. CATHERINE (St. Catherine's).—A Brazilian Fern, of great beauty. Fronds almost triangular, pinnate; the leaflets blunt and oblong; root-stock creeping, and covered with scales wrapping over each other; seed-vessels in one series, and only one, the upper part of the leaf. Another elegant Fern, increased by dividing the creeping root-stock.

G. DEFLEXUM (Bent-down).—Another beautiful production of that prolific country, Brazil. Fronds pinnate, growing two feet in height, with the leaflets bent down and undulated. Stems dark green; and seed-vessels in two rows. Root-stock scaly and creeping, by which it may easily be increased.

G. HARPEODES (Seimitar-like).—A tall-growing, rather coarse Brazilian Fern. Fronds pinnate, the leaflets curved in a seimitar-like form. The fronds stand nearly erect upon a stem a foot or more long, and often the frond itself reaches the height of three or four feet; hence, it should only be grown where there is plenty of room. Seed-vessels large, and in one series. Increased easily, by dividing the thick, scaly, creeping root-stock.

G. INCANUM (Hoary).—A West Indian Fern, of a dwarf habit. Fronds pinnate, lance-shaped, and densely covered with hoary scales; leaflets obtusely oblong, and leathery. The plants grow about nine inches high. Seed-vessels in one series. Veins indistinct. Root-stock creeping and scaly. Increased by division.

G. LATICES (Broad-footed).—A Brazilian Fern, of a neat habit. Fronds pinnated, slender, and drooping,

growing eighteen inches high; leaflets long and narrow, undulated, and spreading; seed-vessels small, and in two ranks. Increased by dividing the bright green, creeping root-stock.

G. MENISCFOLIUM (Meniscium-leaved).—A tall-growing Brazilian Fern, of great beauty, arising from the beautiful arrangement of the angulated veins. Fronds pinnate, growing three feet high; the leaflets are six inches, sharp, lance-shaped, undulated or wavy, and of a shining, bright green colour; seed-vessels large, often in two rows, and of a yellowish colour; stems bright green, and jointed on the creeping, scaly root-stalk. Increased by division. A truly elegant Fern, but requires plenty of room to show off its beauty to advantage.

G. PILOSELLOIDES (Pilosella-like).—A West Indian, low-growing, creeping Fern, suitable for rustic baskets to suspend in the stove. Fronds simple, sterile, covered with light-coloured hairs, oval-shaped, and only two inches high; fertile, hairy, narrower than the barren fronds, and grows nearly double the height; seed-vessels in one series, and each surrounded with narrow scales; root-stock slender and creeping. Increased very readily by division.

G. SUBAURICULATUM (Half-eared).—From the Isle of Luzon. The most beautiful Fern in the genus. Fronds pinnate, growing four feet long; leaflets long and narrow, bright green, and subauriculate at the base. The fronds being long and slender, they are pendulous; hence it is a grand plant for a basket. There is a plant of it at Kew so growing, that has nearly twenty full-grown fronds, some of which are nearly eight feet long, with a centre stem not more than eight inches long. This is a noble, elegant plant, and this is the way the plant ought to be grown to show its beauty. Increased by seeds only, though sometimes young plants are produced on the root-stock.

T. APPLEBY.

(To be continued.)

GARDEN FENCES—WALLS.

ALTHOUGH it often happens that circumstances determine not only the shape and size of a kitchen-garden, but also the description of fence by which it is surrounded, yet there are cases in which a choice can be made, and in such cases some discretion ought to be used, as an error run into in this respect is not so easily rectified as one affecting a less permanent structure; and as the subject is one of great importance, the readers of *THE COTTAGE GARDENER*, will, perhaps, allow my entering into it more fully than on matters having a more transient existence; and in going through the subject, I will endeavour to notice some of the different structures or fences which have either been used or recommended as suitable for the purpose in question.

Many years ago, I had the management of a garden which had been formed by a gentleman as well skilled in mechanical science as he was in horticulture and the other branches of Natural History, and in this garden he had introduced many novelties, or, at least, such as were regarded so at that time; and amongst others, fences and other contrivances for training fruit-trees were plentifully scattered about, and, certainly, the best substitute for a brick-wall that ever I saw was of his contrivance, in the shape of a wooden one of the ordinary height of ten or twelve feet. This wall, if it might be so called, was not exactly straight, it being formed in divisions of just such a length as to hold one tree, and which stood in a sort of zig-zag line to the general direction of the whole. Thus, for instance, supposing the general direction to have been from east to west, then the first division of twenty or more feet (for I have forgotten the exact dimensions) presented a

south-east aspect, while the next length would be south-west in a similar way, and the third would be full south, and then another south-east again, and so on; these breaks serving the purpose of preventing that onward current of cold air which it was supposed acted so seriously in preventing trees from bearing well or ripening their fruit. It is, however, proper to observe, that the angular positions above given were not quite so much as is represented by a full south-east or south-west exposure, but the general direction being, as I say, to have a full south aspect, the divisions were so arranged as to present a few points bearing east or west of that direction, and though the appearance was, in the opinion of some, rather singular, it was not unsightly, and the trees seemed to be benefited by it. Observe, as I say, it was built of wood; a strong framework was set up like high posts and rails, and on the sunny side of these deals about one inch thick were secured upright, and fitting as close as they could be made at the time, a slender stone kerb run along the bottom, merely to prevent the boards from resting on the ground, and the top was surmounted by a sort of coping-board, not projecting more than two inches, although its width might be increased; but this I think is rarely called for. It was tarred over to save it from the effects of the weather, but paint might, perhaps, have proved a greater preservative, but I am not altogether sure of that, but of this I may speak hereafter; suffice it to say, that in addition to the upright framework which supported the boarding aforesaid, a series of braces were placed at the back to support it against the effects of trying winds, which certainly did not add to its appearance on that side, but they could not well be done without; the front side, however, was plain and smooth, the upright posts, &c., being flush with the boarding.

This wooden wall was covered with Pear-trees, which did very well on its sunny side, the back being appropriated to Currants, &c., which did well likewise, and to young gardeners it formed a capital place to nail on. One evil, of course, it had, if it could be called an evil, the boards always got so much sun-dried in periods of hot weather as to occasion considerable openings between, at these times, and, consequently, admitting currents of air both ways; whether this was prejudicial or otherwise, I will not take upon me to say; I should feel inclined to think that at the time such currents of air took place the warmth of the atmosphere was such as to render it useful, rather than otherwise, and as the openings swelled up during the winter, the effects at the time the trees were in bloom was not felt.

Now, though the above differs but little from the ordinary close paling fence, against which it is not unusual to train fruit-trees, yet, as it was much higher and destined to act as a garden wall, I here adduce it as one that was in existence, and answered well, and it certainly as much deserved to be copied as some other contrivances of more recent origin, this being made, I believe, in the early part of the present century, was, some thirty years ago, well covered with trees, and though it did not deserve the poetic name of being one of the "wooden walls of old England," it must now be an "old wooden wall."

Our readers will, perhaps, remember, that in some of the early numbers of "*London's Gardener's Magazine*," a plan was suggested of having walls built of slates, held together by frame-work of some kind or other, the slates to be made moveable, and the frame-work also, in order that it might be made to do duty to trees planted on trellises in various places, or, when made stationary, it was expected that trees being planted on both sides of it, a considerable amount of heat would be transmitted through to hurry on the growth on the shady side, more so than would likely be done by a brick-wall; and some

enthusiastic cultivators suggested that the slates being made movable they might be slipped out and placed behind the tree that had been denied the all-important benefits of sunshine; whichever of these ways were adopted, it was expected that an advantage would accrue from such a dark body as slates absorbing so much solar heat, but it was forgotten how cold a substance it was at other times, and that if it speedily received heat from the sun, it quite as quickly parted with it; besides which, the trouble and expense of moving such an intricate piece of mechanism put it beyond the wishes of those who might have adopted a more simple and efficacious plan; at all events, the plan never became popular, and but few were erected on this rickety principle, yet, it doubtless afforded a good hint to those who have since carried out the idea of having two tiers of trees in a narrow enclosure, which they designate a "glass wall;" for the trees I speak of, being planted and trained back to back, with the slate between them, it required no great amount of ingenuity to adopt another substance for slates, and to place it on both sides of the trees it was intended to protect, but as these are merits attached to glass coverings, which slate has no claim to, it is only proper to observe, that at the time the latter was adopted glass was too expensive to meet the wants of every one, but it is now, perhaps, the cheaper article of the two, while its utility, in many ways, is so great, and so varied, that I must leave for another time the task of detailing the uses it is applied to as forming a part of the "garden fence," to which this chapter is devoted. I must, also, leave the other descriptions of boundary lines for a similar paper, as well as the upright, arched, and hanging trellis, and the other mode by which a division is made between one part and another, and as such form important features in a garden, a few notes to enable the amateur to choose the one most adapted to his wants, will, probably, be useful.

J. ROBSON.

THE FATTING OF SHEEP.

(Concluded from page 386.)

HAY is also a most valuable and important material in the fattening of Sheep; it is, however, with the exception of straw, the most bulky of all our dry kinds of food in use, compared with the nutrition it contains; and in the case of feeding ruminating animals its use is very desirable, the bulk being requisite to assist digestion in animals of this class. The sort of Hay which may be designated as Sheep Hay, is that composed of all the finest and most nutritious of the grasses; and as the selection of these varieties of grass, and the method of making the Hay, is a matter upon which the value of it will depend, I beg to refer my readers to the article I inserted upon the subject in *THE COTTAGE GARDENER* for the month of June last. It may be shortly stated, however, that the White Dutch Clover and the Trefoil or Hop Clover are the best, and of the grasses no sort can be compared with the Italian Rye grass for the making of first-rate Sheep Hay.

After having gone through the whole catalogue of feeding materials commonly used for Fattening Sheep, and somewhat in detail, it is now time to treat of the mode of feeding, for although this part of my subject may be considered by many a very plain and simple process, yet my experience has shown me that ignorance or gross neglect prevails to a great extent in connection with the

detail of feeding fattening Sheep. It is not only necessary that all the best feeding substances should be prepared, and ready at hand, but it is also essential that the animals should receive their allowance of the different kinds of food with great regularity, and at a particular time of the day; at the same time, the quantity given should not be in excess of their requirements, otherwise great waste must be the result.

In commencing the fattening process with a lot of Sheep which have been kept previously only in store condition, it is not right to allow them a full quantity of rich feeding substances at the onset, but they should be accustomed to it by degrees, in order that they may make gradual progress, and that the material used in feeding may afford the most profit, as poor Sheep will not yield a good return for a full allowance of rich food, nor will the constitution of the animals endure it without great risk and loss of health.

Upon farms containing mixed soils, the warmest and driest land should be selected during the winter months, but generally after the middle of March, Turnips may be fed upon cold or clay soils with advantage. In feeding the varieties of common Turnips upon dry land in the early part of the season, and before the Sheep are far advanced in condition, they may be allowed to eat the roots upon the land. Tegs, or two-teeth Sheep, when they commence feeding the Swedish Turnips, and which they ought to do in the months of January or February, should receive their food cut and placed in troughs, this being requisite not only for the purpose of consuming the crop without waste, but inasmuch as, about this time they usually shed their teeth, they cannot, therefore, be made to eat their roots uncut advantageously.

The preparation of food is the next point to be considered. When Turnips are prepared in readiness for the cutter, it should be done with care, and in order that the roots may be consumed without waste they should be entirely free from earth. This work is often done in the most imperfect manner—large chips of the Turnip being cut off with the rootlets, as also the stem or neck of the bulb, which, being left on the land, are trodden under foot and left unconsumed; for I find, when Sheep are well-fed at the trough they will not eat anything off the land. It is, also, necessary that a provision should be made against a period of severe frost, which, in case it occurs at all, usually happens in the month of January; and when the system of pitting the whole crop is not adopted, a sufficiency of Turnips should be heaped and prepared to feed the stock through that month. In preparing Oil-cake for feeding, it should be broken fine, with as little dust or meal as possible. When any of the pulse or grain crops are used for feeding they should never be ground into meal, but merely crushed—this will prevent waste; nor should they be used in the whole or entire state, because any of the grains being dropped on the land may vegetate and mingle with succeeding crops.

I am now arrived at that part of the subject which relates to the manner of feeding, but having omitted

my remarks upon the preparation of Hay, I beg to say that it should always be ready at hand. When convenient, the rick of Hay ought to be made in or near the field of Turnips, as this article is never so good for feeding as when it is cut out of the stack and given immediately; where this is not practicable, a moveable Hay-house should be kept in the field, where three or four days' allowance may be held in reserve in good condition. I am aware that the method of cutting Hay and feeding as chaff is approved by many parties, but I am of opinion that it does not answer a good purpose for fattening Sheep; but having gone into the subject in detail in my paper upon the management of Forward Ewes, I beg to refer my readers, who may require information upon the subject, to No. 273 of THE COTTAGE GARDENER. My experience has taught me that fattening Sheep should receive their food in the following order—The first thing in the morning, and in the short days of winter, as soon as the shepherd can see to work, one-half of the daily allowance of cake or corn should be given; immediately after which, the morning bait of Hay, in such quantity as they will eat readily without waste; the troughs should then be supplied with cut Turnips, Mangold, or Carrots, whichever root may be in use, at intervals during the day; about three o'clock in the afternoon, the second moiety of cake or corn should be given, followed by the afternoon allowance of Hay. It is necessary to supply Hay early in the afternoon, otherwise the Sheep are apt to draw away to their night lair, after which it often becomes damaged and unpalatable. The last supply should be roots, filling the troughs to the brim, in order that during the long nights of winter the wants of the sheep may be readily supplied.

If the suggestions and modes of management recommended in this paper be strictly adhered to, I do not hesitate to say that Sheep will fatten as quickly, and with as much profit, as can be obtained by any mode of open field-feeding.

When Sheep are fat and fit for market, it is a matter of some consequence as to how they may be disposed of to the best advantage. In drafting them for market, let them be carefully matched, both for size and quality; the large sheep should be sold separately from the lesser ones, as they will then attract two sets of buyers; and when matched in quality, both buyer and seller will be the better enabled to estimate their weight and value.

JOSEPH BLUNDELL.

ALLOTMENT FARMING.—MARCH.

Now will the fortunate holder of a nice little plot of land,—enough to keep him from having to purchase with hard cash his potatoes, carrots, parsnips, cabbages, &c.—begin to take fresh heart, notwithstanding the painful gloom of the past winter—one that will be long remembered by thousands. But our Scotch neighbours have an old saying about quarrels, which, I suppose, amounts to this, in simple English, "Let bygones be bygones;" and so say I. Lamentations about the past are but of small value as compared with resolutions, and a stern self-reliance as to the future; and the man who is ever depending on his neighbours or ex-

traneous assistance, may be likened to a weak building, which relies on props and shoring for its security. No individual, no nation, can long stand secure that knows not the value of this high principle of self-reliance; and I doubt not, that by this time our Allotment readers, in general, scarcely need reminding of such things. One thing may here be remarked, and most consolatory it is—the tendencies of the age are benevolent, inasmuch as all orders of society in our favoured land daily perceive, more and more, their mutual dependency on each other; and the knowledge of this, I need scarcely say, is the very basis of social order, of progress, and a bettered condition ultimately among our labouring classes.

The weather, since the late intense frost, has been, in these parts, of the very best kind for the period as to facilitating the necessary operations; and I should hope that my cottage friends have not stood with folded arms until now. They scarcely need reminding of the vast importance of digging ground whilst it is in a tolerably dry or mellow state. Some people have an idea that they must wait until a few days before sowing time before they dig their plot, but this is nonsense. I am prepared to admit, that when soils are exceedingly stubborn it becomes a question as to when and how they may be best fitted to receive the intended crop. But, now let us see what ought to be the cropping policy of our little gardens for the ensuing year; for it is by no means essential that every year's cropping should be the same.

I would here once more impress our allotment friends with the fact, that the culture of plots is by no means obliged to be the same as that of their more countryfied friends. As for the price of wheat in another year, no material opinion can be formed; it has risen to a fearful height this winter and spring, and well must it have been with those holders of small plots of land who took our constant advice of laying out most of their strength in cultivating such roots as Parsnips, Carrots, Swedes, &c., instead of ephemeral summer crops.

I would again repeat the advice formerly given, to adhere to such maxim; for, what with a grievous war, and the possibility of another slender harvest, and other considerations, we must not, I fear, expect very cheap bread for some time to come. And I may here urge the importance to those who held plots near to towns or markets of trying their hand at something that will sell well, especially such light matters as will afford them a chance of a few Turnips, Coleworts, or other greens, afterwards; and, as before observed, the *Horn Carrot* is a most eligible thing. If any one is still inclined to try a few beds, he may yet carry out his views by proceeding immediately; although they should have been sown in the middle of February. The seed should be well rubbed, and then mixed with damp soil, and set in a warm place, in a room with a fire in: it will be found to have commenced germination in about three days, and must then be immediately removed to the coldest place in the house for three days more, and then sown. The soil should be in the most friable state, and they are by far best in beds elevated six inches above the ground level. We sow them in cross rows made by the finger, at four inches apart, and thin them slightly when little plants. This done, they may be bunched and sold for a good deal of money in May and June, and the ground at liberty, by the end of the latter month, for a full winter crop of roots or other vegetables.

I would point, too, to what are termed *Early Coleworts*, or Cabbages. I fear, however, the imperious Ice King has been a severe meddler amongst these usefals. Those who are fortunate enough to possess lots of these, will do well so to scheme their cropping affairs as to allow rows of these a place for awhile, especially where the soil is good. There will be no necessity for suffering them to become Cabbages, in the ordinary sense of the term; such has been the character of the past winter, and such the position of the rising spring, as regards the vegetable question, connected with high prices in other things, that there is sure to be a keen demand for these things until June, especially in the vicinity of thriving commercial towns. In these days of steam, I call it "vicinity" when a garden is close to a line of rail, although twenty or more miles from the market.

Early Lettuces, too; those who have secured nice winter plants, and have them, as mine are, fresh as a daisy, on well manured soil, in warm corners—what a good article would

they be for the allotment holder or cottager to push into the market in the middle of May. Indeed, it is much to be lamented that our manufacturing and agricultural labourers, who held a nice little plot of land, do not better understand their position in regard of these market matters. There really needs a little, highly-condensed hand book to guide them; a waistcoat-pocket affair; but, to be really useful, it must be written by "one who has whistled at" the spade.

And now, after speaking of schemes and policies, let me turn to the genuine old-fashioned work of the month.

First—are your plans of cropping determined on? If not, you are much to blame. Set to and decide immediately. Above all, take care to secure some good *keeping roots*; and if you cannot eat them your pig will. I need not repeat them here; you know all about them and their importance. The past winter will have taught you a lesson you will not speedily forget. Let your cropping scheme be so planned as that two-thirds of it shall be in the main intended for *keeping roots*, unless you can comprehend my suggestions as to market work, when you are welcome to plan as you please. Remember, that most of these roots require deep digging, and most of the manure at about a foot to half-a-yard below the surface. They thus obtain the most power when most needed—say from the end of June to the end of August. But it is well to do even more, and which I have frequently suggested in these pages—to do what our great agriculturists do—to use a little dressing in the drill, for it is of the utmost importance for young seedlings that when they come up that they be strong plants betimes. Our readers will remember that I have repeatedly advised a soot compost for this purpose.

Parsnips must be got in immediately. I sow in the third week of February. The ground, being prepared for Mangold or Swedes, may either have early Potatoes between the lines intended for the root-crops, or a few roots of early Coleworts may be obtained from it. Anything which will be cleared off the ground by the early part of July. A provision, indeed, must be made, by some means, for a few *Cabbages*, but they should not be permitted to occupy ground as a principal crop; plenty of spaces will be found for them.

Onions, if not sown, may be got in by the middle of March. The ground deep dug; a little manure kept well down, and a little of the soot and guano mixture sowed by hand over the seed before sowing it over. Let the beds be rolled hard after sowing when they are very dry.

Peas may be sown for a full summer crop in the first week, choosing the *Redman's Imperial*, which rises about thirty inches high. The cottager should make this his last sowing.

Broad Beans.—The last planting must be got in immediately; indeed it is getting full late for a full crop.

Turnips.—A few of the *Early Dutch* may be sown on any spare border in the early part of the month; they are, however, more a luxury than a profit.

Lettuces.—A little of *Aly's cos*, or *Bath cos*, may be sprinkled in with the Onions, to be transplanted between other crops; and it will be well to sow a good sprinkling again towards the end of the month, as plants from these two sowings will be much larger than any during the remainder of the summer. Indeed, March and July are the two months in which Lettuce sowing becomes most profitable, and three sowings should be made in each by those who keep a pig, as their waste leaves and stems are capital pig feed; to a sow with pigs more valuable still; whilst Lettuce is peculiarly the cottager's salad, and known to be not only wholesome but nutritious.

Spinach may be sown to advantage in the first week of March, as a mixed crop, but must on no account occupy land as a principal.

A little *Cabbage* of a dwarf kind, such as *Matchless* once was, should be sown once a month until September. Towards the end of the month, or in the early part of the April, the larger *Carrots* may be sown. The middle of April, however, is a safer period. As to other little proceedings, such as sticking Peas, filling up Cabbage blanks, planting half-a-dozen Red Cabbages to pickle, and so forth, the allotment man will of himself remember all about them. I here try to remind him that the hoe or fork must be kept agoing. *No quarter to Weeds*, must be the motto. If the first spring weeds are allowed to go to seed, one might fancy the owner

by no means an idle man, inasmuch as he has thereby provided himself with a doubled amount of labour.

Finally; let all cultural processes but planting-out be done when the soil is dry.

R. ERRINGTON.

APIARIAN'S CALENDAR.—MARCH.

By J. H. Payne, Esq., Author of "The Bee-Keeper's Guide," &c.

BEE'S GATHERING POLLEN.—Bees may now be seen upon a bright day in the Aconites and early kinds of Crocuses, collecting the little pollen and honey which they afford; and it is but little indeed—only just sufficient to arouse the workers to activity, and the queens to depositing their eggs; therefore, without careful and constant feeding, death by starvation must follow; for I imagine that not one stick in ten has sufficient honey in store to support it through the winter and early spring.

FORSAKING HIVES.—Where the population is low, and little or no food in store, the bees are very likely, upon a fine and mild day, towards the end of the month, to forsake their hives entirely, and to join themselves to more populous and better-stored communities. This desertion, when it happens towards the end of April, is frequently mistaken for an early swarm; the only means of prevention is to keep them well supplied with food; but even this will not, in all cases, keep them from leaving their hives.

WASPS.—It will be well, during the present and the next month, to be looking for queen-wasps, and destroying every one that makes its appearance. A garden-syringe, as I have already said, is the most useful thing I have ever found to effect their destruction, for if discharged at them, it brings them to the ground, and the foot then finishes the business.

DORKINGS AS RECENTLY EXHIBITED.

If the value of good Dorkings has greatly increased during the past year, the quality of these birds has certainly made a proportionate advance. Such a result speaks most favourably for the good already accomplished by Poultry Societies, against which the charge has been so often levelled, that, however advantageous for the purposes of the fancier, they would have little effect on the breeds that were destined to provide for the wants of our tables. But since the farmer's fowl, as the Dorking has been not inaptly called, has thus prospered under their auspices, and to no other cause can their present position be justly assigned, their avowed object, "the improvement of the various breeds of domestic poultry," has, in this instance, at least, been admirably effected.

The Exhibition of the Royal Agricultural Society at Gloucester, in the summer of 1853, brought together by far the best collection of Dorkings that had ever been submitted to public notice; but manifest as the improvement on that occasion, it was even surpassed by the display at Bingley Hall, in December of the same year. In the expression of such an opinion, full weight is attached to the relative conditions of the two shows, of which the former, in a great measure, consisted of young chickens, whose subsequent appearance, in many instances, at Birmingham, presented them in a more matured form.

A few years since, mere size, and that, we imagine, often falling short of the present average, was mainly regarded by the breeder, to the exclusion of both feather and form, and since in this light the characteristic feature of the race, the fifth toe, matted little, the large Surrey or Sussex fowls destitute of this supernumerary number would have answered all his requirements. But now we have not merely advanced with respect to feather, but the well-bred Dorking of the present day, in its improved form, gives a larger proportion of flesh compared with offal to that produced by its four-clawed connexions, and taking the best specimens, no loss of weight, we believe, need be submitted to.

But there are few persons so indifferent to external appearances, that where beauty of plumage can be combined with the economical properties of a fowl, a preference will not be awarded to the bird thus distinguished over that

which lacks the same advantage of good looks. Not merely, indeed, have the coloms of the Dorking improved, but the plumage now frequently attains a degree of firmness and condition in strong contrast to the loose-feathered specimens that breeders were formerly content with. Dorkings, it must be admitted, cannot be bred true to colour, as that phrase is understood with many other families of fowls, but this great point of "condition of feather," indicative of health and vigour, and so agreeable to the eye, may now be easily attained throughout the various shades and distinctions of their colour. And here the great point of excellence, combined with figure, in which the Dorking pens of 1853 have stood pre-eminent.

That these two essential qualities have been gained, to an extent not previously witnessed, will hardly be contested; nor, as has been already intimated, need a comparison of present with past weights, taken as an average of good birds, be apprehended as tending to show that the improved form and feather has been gained at any sacrifice of weight, so material a consideration with the poulterer and his customers. Cockerels exceeding ten pounds, and pullets weighing down the scale at eight pounds, having been no very uncommon productions.

The black and mottled-breasted Grey Dorkings, in their various shades, have generally headed the list of awards, and the Pencilled, Spangled, Golden, Red-Speckled, and Cuckoo sub-varieties have been by no means dangerous competitors to the former. It might, indeed, have been wished that the red birds in particular, of which there is more than one good strain, had been more encouraged, for they are remarkably handsome-feathered birds, and they are, moreover, well spoken of in respect of vigour of constitution. The Cuckoos, also, are often extremely compact, though, perhaps, somewhat deficient in size. Several of these latter have appeared at exhibitions, in the class for "any other distinct breed," while every evidence of real Dorking blood was present. The "*Cuckoo fowl*," indeed, is an erroneous designation when applied in this manner, being simply the distinction of colour, which is often assumed by fowls of various separate families; thus we have Cuckoo Dorkings, Cuckoo Polands, Cuckoo Game-fowls, and, a little-to-be-desired sport, Cuckoo Shanghaes, all of which should, of course, appear with their respective families.

As in Dorkings, almost every colour (black and white alone excepted) may be produced from the same parents, so, also, in respect of comb, which may appear in its double or single formation in chickens from the same birds. The same laxity, therefore, should be observed on this point as with plumage, more especially in a case like the present, where the supply of the table is the main object to be kept in view; for to judge these birds by the same arbitrary standard applied to the fowls bred with especial reference to feather, such as Bantams, Polish, and the Hamburgs, would be most unwise. The comb, whether single or double, if good of its kind, will make no difference in the award; individual opinion or fancy, may, indeed, give a preference, but no judge should lay greater stress on one than the other. It has been sometimes said, that the double-combed are, on an average, the heaviest birds, but it is but fair to add, that authorities of equal experience are found to hold to the contrary opinion. The "*old original*" Dorking seems to have been a single-combed bird, and the double-comb, with the uncertainty of colour, as, also, in many cases of the fifth toe, may east suspicions on the primitive ancestral position of the coloured Dorking of the present day, to which its delicate constitution, and the constant necessity for the introduction of fresh blood, may be regarded as adding weight; but this is not the fit place for the discussion of that knotty point. The coloured Dorking pens, we should notice, are constantly ill-matched in respect of colour, even to an extent beyond what the natural difficulty already mentioned is sufficient to justify, and many a prize has, doubtless, been thus lost.

In White Dorkings, the past year has seen little, if any, improvement; their smaller size, their alleged greater delicacy in rearing (in which, however, the writer of these notes does not concur), are points which induce a preference to their coloured relations. Good specimens, however, have been shown on various occasions, but even

these have not been such as to justify a belief that they have shown an improvement on former years. Many of their pens have been disqualified by blue, or otherwise discoloured legs, and the single-combed specimens, to some of which prizes have been awarded, had, in many eyes, no title to that distinction, the double comb appearing in every way to become the White Dorking.

It is singular that 1853 should have witnessed this great change for the better in the Dorking fowl; since, for very many seasons, no more fatal period has been known to their breeders. Young and old, but the former more especially, have died under every possible condition of climate and management. That under circumstances so unfavourable, Dorkings should have been able to emerge from the rack, and secure a good place among the first ranks of their most favoured competitors, argues great intrinsic merit on their part, and warrants the expectation that even more may be anticipated. Fifty guineas have lately been paid for a single pen of Coloured Dorkings, and the same sum refused on more than one occasion; and Captain Hornby finds no difficulty in parting with his surplus stock, even at as high a rate as five guineas per bird. So remarkable an increase in value becomes still more striking when it is remembered, that although Shanghaes have frequently gone beyond these sums, they were recent introductions, carrying with them the charm of novelty and fashion, in addition to their own real good qualities; but with Dorkings the case was different; both the name, and the bird itself, in many degrees of merit, were familiar to us, and highly commended as it was for the table, any such commanding position in the annals of the poultry world was never thought of; and had the probability of their attaining their present value ever been alluded to, a mania, even more absurd than that of the Shanghaes, would have been assigned as the motive of so absurd a conjecture.

The south-western counties of England are generally deficient in the coloured Dorkings; and when really good birds are there shown they are generally but visitors from other districts. The Reigate Exhibition would have reasonably been regarded with great interest by the Dorking breeder, as likely to produce the best specimens from the very head-quarters of the family; but, if we remember rightly, the limitation of the exhibitors to those resident within a given distance of that town tarnished the laurels that were there won. Gloucester and Birmingham, indeed, have proved that the Sussex air is not essential to the Dorking's well-doing; and another season, if this county and Surrey desire to retain the celebrity in this class of fowls, gained in former times, and so long creditably sustained, the lists must be thrown open, and the competition of England invited.

HARDY BORDER PLANTS.

ACONTIUM OCHROLEUCUM.

THE GREAT PALE YELLOW WOLFSEANE.

THIS is one of the largest of the hardy border plants we have, and a noble plant it is when in bloom, and so very suitable for plantations where a few or many kinds of hardy herbaceous plants are planted by those who are anxious to have as great variety as possible in a limited space. As I have said before, this is a grand plant for such places, or for a centre or back-row plant to marginal borders to flower gardens, such as Mr. Beaton so frequently speaks of, recommending the marginal borders to be filled with hardy herbaceous plants, and the centre beds with bedding plants; and such borders can be filled with a choice selection of these beauties, to be quite as interesting, if not more so, as the centre beds are which are each filled with one kind and colour. Whatever kinds of hardy plants were used to fill one of such beds, the same might be used to fill the corresponding bed on the opposite side; or if not precisely the same kinds, such plants should be used that would flower at the same season, and be of the same colour and height; but the best effect will be produced by using the same kinds of plants.

A. ochroleucum is a very strong grower, but not a rapid spreader, its crown being very compact, and its roots all

fibrous, which extend round its crown for a considerable distance. It is readily increased by division in the spring months, if such be required, or it may remain in the same spots for almost any number of years without becoming straggling or tiring of its situation, if its roots are not cut and chopped about at the times when the borders are being dressed off. At those times, rather place a spadeful of nice fresh earth over and round about its crowns, after weeds, &c. are cleared away. This kind, like all the others of its family, dies entirely down during the winter months.

Its leaves are all deeply lobed, and its segments coarsely notched and pointed. The stems rise from four to even seven feet high, according to the strength of the plant and the soil and situation it is growing in. Its stalks put out an abundance of side-shoots or branches, which all form panicle-like spikes of flowers, which are of a palish yellow colour, forming, upon the whole, a very striking plant, though not so pretty as the *versicolor* and others. It flowers from the beginning of June to the middle or end of August. It is a native of Caneasus, and introduced to this country 1794. T. W.

TO CORRESPONDENTS.

. We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of The Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

FEEDING IMPRISONED PHEASANTS.—"A. B. wishes to know the best food for common Pheasants. She has had a house put up for them, a wooden shed, with a large outside court composed of wood and wire netting, both house and court being well gravelled; to this they are, of course, always confined. In the court, Spruce Fir-trees are planted for shelter. The court is on a sloping bank, facing nearly south, and well sheltered from north and west winds. The Pheasants are fed every day with oatmeal and water (made of the consistency that it crumbles when thrown down), crumbs of bread, oats, two or three potatoes, worms, cabbages, and turnip-tops, and fresh water every day; but with all this care, three of the Pheasants, a cock and two hens, have died in the last month. In the Pheasantry there are still nine hens and two cocks. Would one cock be sufficient to keep? The Pheasants that died were fat, nicely fed birds, and showed no sign of illness till just before they died; nor was there any mark on them as if injured by vermin, except on one of the hens, where the skin on the back was torn on one place, but it seemed as if the other birds had done it." Not trusting to our own judgment, we sought information from a first authority, and this is the reply:—"I send you what one of our keeper's says; but I believe I know as much about Tame Pheasants as any body, and my notion is, that 'A. B.' is taking too much care of her Pheasants, and that the complaint of which they have died is *over feeding*. I recommend her to stop the oatmeal *entirely*, giving them Indian corn, barley, oats, (wheat occasionally, but not at the present prices), mixed up with chaff, or straw, so that they may not be able to gobble it all up at once, but have to scratch and fad it; at the same time, this would serve to *amuse* them. Pheasants are great gluttons when their food is handy, and they have no trouble in looking for it. I have a cock Pheasant now in my hall, who I saw eat till he died of *repletion*; I saw this. Probably your correspondent, had she examined their stomachs, would have found them choked with fat. I would substitute some turf in part of the court instead of the gravel. Let them also have some lime to peck at, and some cabbage leaves every day. I do not think a cock ought to serve more than five or six hens, and I should be inclined to put one cock and four heas together, and one cock and five hens, so as to prevent the chance of the two cocks fighting. If this Pheasantry is where other *Wild* Pheasants are it is well to have the *top* of the enclosure open, so that the wild cocks may come in and pay their respects to the hens. I have often watched them at this. The inmates have, of course, one wing clipped to prevent their flight." The gamekeeper's note is as follows:—"I cannot conceive the death of the Pheasants was occasioned at all by the food; on the contrary, I think they were taken the best of care of *that way*. I should have preferred, in lieu of the oatmeal and water, *whole* corn and a *diversity* of it; but as the time is coming for laying, care should be taken they are not too fat. A portion of bran with the meal (or *any other*), warm best would be substituted. As to the number of cocks, I should say, decidedly, three hens to one cock; and now they should be penned off, as the cocks will fight and cause the hens to fly and dash about. Should 'A. B.' detect any more dead, the best plan would be to have them *most carefully* plucked of their feathers, and see if there is no injury on them, as it is astonishing what a small blow will kill a Pheasant, and more particularly if on the head, which they are subject to in a mew, and is difficult to detect unless denuded of the feathers. Another hint, too, is worth naming, and that is, what sort of netting is over the *top* of the place of confinement?"

KNOWN ARAUACARIA (A. M.).—It is as natural for Cryptomerias, Arbor Vitae, Cypresses, and many other Conifers, to be *browned* by cold winds, and on calcareous soils, as it is for them to grow upwards; and it is not at all curious that such an unnatural, unpractical, and unscientific way as turning out an Araucaria from a pot, with the ball entire, at the beginning of winter, should cause it to brown. It was a most unguarding way of planting Araucarias. We have often heard of them and of others being planted in their halls, and we have seen them screwed right out of the ground in consequence, but we do not recollect

of ever hearing of any one turning out valuable pot plants at the "beginning of December!" Yet, if the leaves are only browned, and we think that is all the extent of the damage, they will all come right again; but if they are killed, there is no remedy. Try them, here and there, with the point of a knife, and you can easily see if there is life in them. These Araucarias require no covering from the severest frost we experience in this country. They are perfectly hardy, and coddling only hurts them.

COVER FOR GAME (F. W. M. B.).—It is bad practice to head down any tree, and much more so a Spruce-tree, in a game cover. Spruce-trees, sixty feet high and twenty feet apart, the branches just meeting, make the finest game cover we know of anywhere. "Low grounds," if they are at all damp or boggy, must first be planted with trees sure to grow on such soils, as Alders, Poplars, Willows, and Ash, in the way pointed out the other day by Mr. Appleby. Then fill up between the trees with one-half young Privet, the rest with Black Thorn or Sloe-bush, &c., common Hazel, or wild Nut-trees. All these will grow in the wettest soils, and will make an impenetrable cover; but low ground is not at all the right place for game, except snipes and woodcocks.

QUERY (Fitzgerald).—Your description would be referable to a Silver-pencilled Hamburg cock; but we must add, that to name either fowls or plants without seeing the specimens is always an unsatisfactory task.—W.

LIME-ASH FOR POULTRY-HOUSE FLOOR (J. T.).—The lime-ash floor is composed of one-third part refuse lime from the bottom of the kiln, containing a considerable portion of ashes, the remaining two-thirds being what is termed in Cornwall, "*skimpings*," a kind of slaty spar, broken very fine. These are mixed together with the necessary portion of water to wet the lime, and then laid down, being constantly beaten till dry. A far better floor, however, is now made, by mixing together one-third of lime (the best grey and the common, in equal quantities), and two-thirds of the very small pebbles from the shore; this latter is an excellent material for poultry-house floors.—W.

SPANISH COCK (Ibid).—Red is always objectionable on the face of a Spanish fowl, the object of the breeder being a perfect white face. In reference to your question about the price of eggs, you had better apply to Captain Hornby, Knowsley Cottage, near Prescot.—W.

GAME FOWLS (Ibid).—It will not pay to keep Game fowls in confinement, their habits requiring a wide range.—W.

GRAPES FOR VINERY (C. T. J.).—For your Vinery, 15 feet by 12 feet, one West's St. Peter, one Royal Muscadine, and two Black Hambro's, we should plant in your case, and in the order we have placed them,—the St. Peter's at the hottest end. We should be very jealous of a four-foot deep border, unless above the ground level. Plants two years old will be proper, planted in the end of March, the balls of earth unloosed. As to *Climbers*, that is a matter of taste, or fancy, rather; they are numerous, and any respectable nurseryman will safely advise you also as to what plants to cultivate. Our worthy coadjutor, Mr. Fish, in his back papers, has advised about all these things. Your hen Pheasant will, no doubt, "fraternise" with your fowls if you can keep her from "holting." As to food, see among answers "to correspondents" to-day.

GRAPES FOR VINERY (A. B. C.).—Your Vinery is 36 feet by 18 feet. Perhaps you have about nine rafters, but you have not stated. If so, plant as follows:—One Muscadine, or Sweetwater, one Muscat, one Barbarossa, two St. Peter's, four Black Hambro's. Plant in the order they stand here, beginning at the hottest end with the Muscadine. About your *Orchard-house*, all depends on whether you understand how to manage the trees. The construction of the house appears good.

THE PEACOCK IRIS (A. R.).—You are quite right. Mr. Appleby has correctly described *Vicessua glaucopsis*, but inadvertently called it *Iris pavonia*. Mr. Beaton says,—"The Peacock Iris of the seed-shops is the true *Vicessua glaucopsis*. A very light blue flower, with a whitish eye or spot at the bottom. *Vicessua pavonia*, or *Iris pavonia*, of Linnaeus, is quite a different plant; a largish white flower, with the most intensely shaded blue spot at the bottom of each petal, like the spot in the tail feather of the Peacock. I had it twice from the late Mr. Young, of Taunton, and you could buy it for 1s 6d, in the London seed shops, twenty years since, but I believe it is now lost to the country. Mr. Carter, of Holborn, is the most likely person to have it. I said, in THE COTTAGE GARDENER, that both kinds were to be had in the seed-shops—Vol. X., page 441. Mackay (Lows), of Clapton; Colville, Young, of Taunton; and Wheeler, of Warminster; with Young, of Epsom, had it, I believe, when I was a bulb-grower in Herefordshire, from 1829 to 1837; since that time I lost sight of many of them."

DRESSING FOR TREES IN ORCHARD-HOUSES (R. Edwards).—1 lb. flowers of sulphur, $\frac{1}{2}$ lb. soft soap, $\frac{1}{2}$ lb. ground black pepper, boiled for twenty minutes in four gallons of water. If necessary, add enough clay to render it as thick as paint. Apply it, when cool, by the aid of a painter's brush. It must be put on before the buds have opened. Give plenty of air during the day, and moist air at night, to keep away the Red Spider.

SUPER-PHOSPHATE OF LIME (W. V.).—We cannot tell what is the composition of the powder from the Bone Charcoal Works. It will do to make the super-phosphate if it contains the phosphate of lime portion of bones. A handful of super-phosphate, once a-year, in the spring, will be quite enough for one Rose-tree.

SOFT EGGS (J. B. N.).—If you refer to the indexes of last year you will find abundant information on the subject. It arises, probably, from inflammation of the egg passages. Give each hen one grain of calomel and one-twelfth of a grain of tartar emetic. Feed with soft food only for a few days.

ECONOMICAL BREAD.—R. P. H. says,—"In reply to S. E. J., in your number of Jan. 26, I enclose the accompanying receipt, which is now being used by a friend, whence I have to-day returned, and I can state that the semi-rice bread we had at breakfast was excellent, as was also another baking I partook of at the same house last week. $1\frac{1}{2}$ lbs of whole rice, set in a jar, with plenty of water, to simmer all night; any water remaining in the morning to be strained off, and the rice well beaten into a paste. This paste is to be added to the bread *after it has risen*, and well kneaded in. $1\frac{1}{2}$ lbs. of rice will do, and 14 lbs. of flour."

TURPENTINE FOR GAPES (Lucy).—Mr. Tegetmeier gave full directions in our last volume. Shut up the fowl in a box with some spirit of turpentine poured upon a very hot plate, so that it must inhale the fumes of the turpentine. Do not suffocate the bird, and repeat the application daily until the gaping ceases.

DUCKS NOT LAYING (Q.).—Are they old birds? Whether old or young, common Ducks rarely lay in winter unless they are very liberally fed. The Aylesbury and Rouen, however, lay in the autumn.

RICE MEAL (T. L.).—We do not know what are its fattening qualities. Have any of our readers used it for feeding pigs? We will answer the other queries next week.

EMIGRATION (A Young Gardener).—Do you seriously say that £16 is too much for carrying you and your baggage half round the world, and feeding you, running all risks, interest for capital sunk in the ship, &c. Government aid highly-recommended applicants. Full information may be obtained at the Emigration Office, in London.

COLLODION, FOR CUTTINGS (E. C. J.).—This is Guo Cotton dissolved in ether. Mr. Low, in a recent communication to the Royal Society, says he found it most beneficial to dip the cut end of each cutting, whilst dry, into the Colloidion. It keeps out excess of moisture. Of 131 cuttings so treated, 86 rooted, whilst of 131 without the Colloidion plaster only 42 rooted. The experiments were tried upon Stove, Greenhouse, and Hardy plants. Gatta Percha dissolved in naphtha would probably answer the same purpose.

OAK SLABS FOR PARK PALINGS.—M. G. says—"I want them five feet high and three-quarters-of-an inch thick. Where can I procure them? have seen them near Mr. Fish's. I am now in Ireland." We presume you will have no difficulty in getting them from the nearest oak forest where they are falling timber. Choose it of the straightest grain, and not over old. If the stick should be twelve to eighteen inches through, split it with beetle and wedges into four parts, and then run your slabs in feather-edged style, from one inch on one side to half-an inch or less on the other. They then lap over each other, which is generally the way they are put up. After re-feeding, they will want a little dressing with a sharp axe, to make them more equal, and to remove the sap-wood. Such fences will last a very long time. Many make them decay by daubing them with paint, or tar, while in a green, unseasoned state, thus doing something more than having their trouble and expense for nothing.

GERANIUM-LEAVES SPOTTED (M. L.).—It strikes us that your plants have got the spot, from cold and damp; and if the age of the leaves does not deceive us, the frost has also paid them a visit. You did right in removing the worst at once, and, most likely, all will have to go; though, to keep the plants alive, you had better do so by degrees. A higher temperature, say 50° to 55°, and plenty of air in suitable weather, will restore them if not too far gone, but it is not easily got rid of, as it becomes constitutional if let alone. We cannot say anything as to your supposed reasons; for though your writing seems admirable at first sight, and many words are extremely plain, there are others which, after repeated trials, we have been unable to decipher so as to make sense out of them.

SELECT LISTS OF GREENHOUSE PLANTS (S. O.).—We think Mr. Appleby promised a list some time ago. Such lists have often been given, and will, no doubt, be repeated to please you, though they seem the driest and most useless things we have had to do with. Do we quite understand you that the "more select the list, the better it will be," when the chief reason you assign for obtaining it, is the severe winter having killed so many of the plants usually grown in Peacheseries and Vineries? Did you want a list for a definite purpose we would at once endeavour to supply you, though we repeated an old tale to old readers. Very select greenhouse plants are rather more easily lost than those usually kept in Vineries, &c.

BEES REJECTING FOOD (Honey Bee).—Your hives that refuse to take the food given them, are, in all probability, not in need of it; but the weight will decide. We would, at any rate, induce them by some means to take the food. Feed the other hives liberally; give them at least two pounds per week. Send a stamped directed envelope to J. H. Payne, Esq., Bury St. Edmunds, and some seed of *Leucantha* will be inclosed to you.

GOLDEN PHEASANTS (F. W.).—For hatching and rearing these employ Bantams, or a small breed of White Silk Fowls. The latter are not to be surpassed for this purpose.—W.

PULLET DYING ON NEST (E.).—The pullet forwarded died of apoplexy, the predisposing cause being extreme fatness; a dietary consisting in great part of Indian corn meal, and pea meal, &c., is far too fattening and stimulating for fowls kept in an aviary. Indian corn contains, on the average, three times as much fatty material as barley, and is not, therefore, if given abundantly, a good food for laying hens, especially as it is not very rich in those flesh-forming materials out of which eggs are formed.—W. B. TEGETMEIER.

HOGG'S EDGING TILES (An Amateur).—We have received a report from Mr. G. Townsend, of Fordham, Cambridgeshire, in which he states that Hogg's Edging Tiles, which were laid down in September last, "are as sound, after having endured the late severe frost, as the day they were first put down." Those which were placed in "the Society's Garden" were of a different construction, and manufactured of a different description of clay from those which are referred to above.

CALENDAR FOR MARCH.

FLOWER-GARDEN.

ANNUALS (Tender), such as the *Portulacææ*, *Mesembryanthemums*, *Lobelias*, &c., sow, b.; (**Hardy**), sow on dry borders, b. and c.; finish transplanting *autumn-sown* annuals. **BIENNIALS**, sow, c. **CLIMBERS**,

half-hardy, as *Maurandya*, *Lophospermum*, &c., pot and train, b., to have strong for next May planting. **CUTTINGS**; push on the propagation of cuttings, and transplant them as fast as they root. **CUTTINGS** from *Rose* prunings, plant in the shade. **DAHLIAS**, sow, and force old roots for stock, b. **DRESS** every part within the boundary as early as you can. **EDGINGS** of all sorts finish off as early as possible. All **EVERGREENS** transplanted since last August may have liquid-manure this month, and throughout the season after this mild winter. **FLOWERS**, pick off from plants you want cuttings from, b. Finish all the **PLANTING** and **SPRING PRUNING** of trees and shrubs, and all necessary alterations, as soon as the weather will permit. **GRASS**, and white and small yellow **CLOVER SEED**, sow with a liberal hand over patchy grass; keep the grass in clean, trim order, and roll it three times this month, and oftener if you can. **GRAVEL**, clean, roll, and relay. **HAND-GLASSES** are the best of all aids to rear half-hardy, and such other annuals as come up weakly at first; place them on a warm sheltered aspect. **HOING**; never hoe a border in March, for fear of killing something which you cannot see. **HOTBENS** are only good helps to those who can well manage them for the flower-garden; keep them up to 70°, and steady. **HYACINTHS**, and other **BULBS**, as soon as they appear, stir the beds, and lighten the soil round the plants; and plant spring **GLADIOLI** at once. **PERENNIALS**, with the exception of long fleshy-rooted ones, ought to be removed—divided, if necessary—and receive some fresh soil, or be planted in new situations, at least every third season; see to this rule, and treat one-third of each family, every February and March, according to it. **PROTECTION** is necessary for almost all young things of a tender nature this month. **RAKES**, lock them up, b.; if your man cannot dress a border without a rake, tell him he must learn. **ROSES**, finish pruning, b., except, perhaps, a few strong ones may be left unpruned till April, to bloom later; but this plan is radically bad and not necessary now with our perpetuals. **SEEDS**, do not sow a packet of rare seeds in one pot only, sow in two or three pots, to provide against accident to one. **SEEDLINGS** in heat, transplant as soon as you can handle them. **STAKES**; see if you have a stock on hand for your *Dahlias*, *Hollyhocks*, and all other plants requiring them next summer, and see that all the old ties and rotten stakes are out of the rosary. **SWEET BRIAR**, sown in a single row, will grow and make a hedge in such poor soil as would kill other roses. **TURT**, lay. D. BEATON.

FRUIT-FORCING.

AIR, increase as forcing proceeds. **APHIDES**, destroy. **CUCUMBERS**, in forcing-house, apply liquid-manure, train and stop when long enough; in frames, turn and remove linings weekly, stop frequently; temp, 65° to 75°. **CHERRIES**, use moderation; keep a humid air; temp., 50° to 60°, artificial heat; ventilate freely. **FIGS**, such as *Peaches*; keep the root moist; bottom warmth benefits them. **LIQUIN MANURE**, apply to active growths where strength is required. **LEAVES** of all fruits keep clean. **MOISTURE (AIR)**, supply liberally; root moisture regularly, but according to need. **MILDEW**, beware of; see *Sulphur*. **PEACHES** and **NECTARINES**, keep a free atmosphere; dishud and train; temp., 55° night, 65° to 70° day. **PINES**, liberal heat and moisture to rising or swelling fruit; successions, re-arrange and increase temperature. **RED SPINERS**, see *Sulphur*. **STRAWBERRIES**, introduce successions, water liberally, keep near the air and light. **MELONS**, bottom-heat 75° to 80°, air-heat 70° to 80°; thin the Vine well. **SILPUBA**, apply at least monthly in all structures. **TEMPERATURE**, allow 5° or 10° advance in heat during sunshine. **VERMIN**, entrap. **VINES**, early-train, stop, thin berries, tie shoulders; do not forget the sulphur. **WATERING**, attend to daily. R. ERRINGTON.

FRUIT-GARDEN.

APRICOTS, protect: search for the eggs of the Red-bar Moth, like parsnip seeds, and dotted. **APPLES**, cleanse, brine and soft soap, succeeded by spirits of turpentine in the retreats of the American blight. **BLOSSOMS**, retard and protect. **BUSH FRUIT**, still plant or top-dress. **FIGS**, uncover, prune at end. **GRAFTING**, proceed with. **HOING**, practice on foul borders. **NUTS**, hang male catkins among the female blossoms. **PLANTING** of all kinds instantly bring to a close. **PEACHES** and **NECTARINES**, finish training, retard and protect; dress the walls with sulphur paint. **RASPBERRIES**, still plant, prune, stake, and top-dress. **ROOT-PRUNING** may still be done. **STOCKS**, destroy. **STRAWBERRIES**, spring-dress; transplant. **STANDARDS**, stake. **STOCKS**, plant or sow seeds. **TRELLISES**, dress and protect. **VINES**, plant at end. **WALNUTS** may be planted still. In *grafting*, proceed according to the degree of development of the bud, taking each kind the moment the buds actually begin to expand. R. ERRINGTON.

GREENHOUSE.

AIR, admit in fine weather, when the outside temperature is above 35°; a shut house is better than cold currents and night fires; in foggy weather, however, light a fire, to clear and dry the atmosphere. **BULBS** and **TUBEROUS** roots, introduce, and water more freely; start the various kinds of *Achilleæ*, *Gerania*, and *Gloxinia*, in hotbed; seeds of the latter, sown now, will give nice little flowering plants for the autumn and winter, if you can give them heat. **CALCEOLARIAS** and **CINERARIAS**, water more freely; give manure water to those flowering and showing their flower-stalks; shade in sunny weather; shift for succession **CAMELLIAS** and **AZALEAS**, water more plentifully when in bloom; keep those intended for late blooming as cool and shaded as possible, so that frost does not injure them. **DIOSMA**, **EPACRIS**, **HEATHS**, give abundance of air when growing and flowering; Prune freely when done flowering, and keep close until they begin to grow, when the roots had better be examined. Now and afterwards, for a couple of months, will be a good time for inserting cuttings. **HABROTHAMNUS ELEGANS** is now a pretty object, grown in a pot, or trained against a pillar. **HOTBENS**, prepare for sowing *Primula* seeds, and any other desirable greenhouse plants, raising cuttings, sowing seeds, or striking cuttings of the commoner sorts for stocks on which to inarch or graft *Correas*, *Oranges*, *Camellias*, &c.; the grafting of such plants is easily effected in such a sweet, moist hotbed, and does away with much of the trouble of inarch-

ing. Such a bed will, also, be necessary for starting Cockscombs and Balsams, &c. Strong, early, winter-flowering PRIMOLAS should be sown the end of this month; and CINERARIAS intended for the same purpose the month following. INSECTS, destroy. LEAVES and STEMS, clean; a little soap and water is a great auxiliary for removing all kinds of filth; syringe with clean water afterwards. LILIES, JAPAN, after the stems appear, place in a light, airy situation. MIGNONETTE, and tender annuals, sow in slight hotbeds, in pots, turf, &c., to be afterwards hardened off. SOIL, prepare, turn, and expose for a general shifting about the end of the month; but do not knock about fresh soil intended for potting so as to shake the fibre out of it. PRIMOLA SINENSIS will be greatly benefited by manure-water. The double varieties are well worth a little extra attention, as the flowers stand a long time in a bouquet. TRAIN large plants of PELARGONIUMS intended for early flowering; STOP those for late summer and autumn. SCARLET GERANIUMS, intended for specimens in pots, give good shifts to, and if they can get a little bottom-heat they will come all the stronger and bloom the finer. Tie climbers to rafters, after duly pruning them, keeping in mind whether the flowers are produced on young or old wood; train daily those on trellises; and, as the season is now getting on, let neatness, order, and cleanliness, everywhere prevail. WATERING will now be more wanted, and a moistish atmosphere in clear weather, to counteract the drying effects of east winds. SPRAYING the leaves with tepid water, after a sunny day, is as good for a plant as soap and water is for our own skins. Unless in extreme cases fire-heat will not be so much wanted. Old Scarlet Geraniums, stored past, should now be brought into the light, top-dressed, &c.

R. FISU.

ORCHID HOUSE.

ARDEES, and other similar Indian plants, will this month be growing rapidly; give them fresh sphagnum, if in wire baskets; if in wooden ones, renew them, and bring the roots within the baskets amongst the fresh sphagnum. AIR, give more abundantly as the days lengthen, and the sun obtains more power. BLOCKS.—The plants on these must be syringed twice a day at least, as they will now be growing rapidly. BASKETS.—Dip these in the cistern twice a-week; if very dry, allow them to remain in the water an hour or so, till the hard lumps of peat are thoroughly wetted. BARKERIAS, set to work, by giving water freely. Pot CATASETUMS, CYCNOCHES, and other similar-habited plants; they will now be growing. DENDROIDES, see last month. Such as are in flower remove, if possible, to a cooler house; they will then last much longer in bloom; those growing repeat. HEAT, towards the end of the month bring up to the maximum. Indian House, 80° to 85° by day, 70° by night, Mexican House, 70° to 75° by day, 60° by night. The highest heat to be when the sun shines. INSECTS, keep a watchful eye upon, and destroy the moment they are perceived. MOISTURE IN THE AIR, keep up a large amount of, by keeping the walks, platforms, and walls frequently flooded. POTTING, proceed with, and finish before the end of the month. Now is the time to increase orchids, by division or otherwise. SHADING.—About the middle of the month place the shades upon the roof, to be ready for use, as the sun will soon be so powerful as to be dangerous. STANHOPEAS, now growing, put in fresh compost in large baskets. STEAM, where possible, admit amongst the plants. WATERING AT THE ROOT must now be regularly given, but care taken that it does not lodge upon the leaves or in the hollow of the young shoots.

T. APPELBY.

PLANT STOVE.

ACHIMENES advancing in growth, give water to, but do not flood them in this early season; repeat such as have filled their pots with roots; pot a batch to succeed the former ones. AIR, give now freely in mild weather; take care the apertures for the admission of air are not directly opposite the plants, it is best to come over the pipes or flues, to be heated before it reaches the plants. AMARYLLIS AULICA, and varieties, repeat, and place in heat. APHELANDEAS, repeat. BASKETS. Place in these *Zschynanthus*, *Achimenes*, some *Lycopodiums*, and other hanging-down plants; they ornament the stove greatly. There are some baskets, made of coloured glass, that are very ornamental objects filled with proper plants. CLIMBERS will now be growing fast; attend to training and thinning shoots; in pots place fresh trellises to, and keep the plants constantly trained around them. CUTTINGS continue to put in; pot off such as have rooted. HEAT, increase to 70° by day, 60° by night; winter-blooming plants gone out of bloom cut in severely, and place in a cool house to rest. IXORAS, repeat, stop, and tie out; place them in a frame heated with dung; here they grow rapidly and soon make fine plants. INSECTS, continue to watch for and destroy. POTTING, finish the spring, by the end of the month. SPRINGE freely morning and evening, and keep the paths flooded in sunshine. WATER will now be required in large quantities to fast growing plants. Let the walks be frequently washed out, and every yellow leaf removed, every plant neatly tied, and decaying flowers removed as they occur.

T. APPELBY.

FLORISTS' FLOWERS.

ANEMONIES, double, protect from frost. ARICULAS and POLY-ANTHUSES will now be showing their flower-stems. In this stage they will require constant attention. Top-dressing, if not done, must be finished the first week; water regularly in pretty liberal quantities; if allowed to flag now the blooms will be small. Give plenty of air daily, and shade from bright sun towards the end of the month; cover up securely at night whenever there is the least appearance of frost; sow seed, and pot last year's small seedlings to encourage growth. CALCOLARIAS, repeat, prick out seedlings, give plenty of air to, and smoke frequently with tobacco. CARNATIONS and PICOTEEAS, put into their blooming pots. Search the soil over minutely to find wireworms, and destroy them previously to using. Place them when potted upon a bed of coal-ashes, with a convenience of hoops and mats to shelter them from severe weather. Should mildew appear, dust with sulphur; and destroy green fly with tobacco-water or Scotch snuff. CINERARIAS finish potting, b.; smoke frequently to destroy every green

fly soon as it appears; water freely, and shade from bright sun as the flowers open. CHRYSANTHEMUMS pot off into small pots and repeat, b. in a size larger. DARIAS, all intended to be potted should now be done; pot off cuttings as soon as rooted, and put in more cuttings if required. Divide the old roots, leaving a bud or two to each division; place each division in a pot, and allow them to grow slowly till planting time; a cold frame, well protected from frost, will be shelter enough for them. FUCUSIAS, repeat; cuttings may yet be put in. Begin to train early, in order to form well-shaped plants, HYACINTIS; tie the flower-stems to sticks, to prevent the winds from breaking them off; continue to shelter the bed by hoops and mats. HOLLYHOCKS, plant out where they are to bloom; place a mulch of short litter round each plant. PANSIES, top-dress; in pots, lay down the shoots round the plant, cut the stems half through to induce roots; shelter from heavy rains and severe frosts. PELARGONIUMS, pot young plants; top-dress old ones, and tie out to form large, spreading specimens; smoke frequently, to destroy green fly; when the flower buds appear, give liquid-manure every third time watering. PINKS, top-dress, b., if not done last month. RANUNCULUSES may yet be planted, b.; shelter the bed from heavy rain, frost, hail, or snow. TULIPS will now be growing fast; shelter the young plants from heavy rain, or other severe weather; if rain falls during the day, and a sharp frost intervenes at night, and no protection is given, the young leaves will be much injured. VERBENAS, in pots for exhibition, repeat, tie out, and nip off the tops of the shoots; shelter both these and those intended to plant out from frost; smoke frequently to keep down green fly, and syringe occasionally with sulphur-water to destroy or prevent the red spider; put in cuttings of scarce sorts; sow seed; look for slugs constantly in the frames under the pots, or any other lurking place, and destroy them. Finish planting ROSES, and place those in pots in a warm house, to be coming on for the June or July exhibitions.

T. APPELBY.

KITCHEN-GARDEN.

This is a busy month—every day brings its work; a favourable opportunity should never be lost for doing any particular kind of work; take advantage of open mild weather for every kind of planting; in taking up transplanted plants from nursery beds of any kind, or at any time, always lift them up with some kind of tool or other, as a plant thus transplanted always suffers so much less than a plant drawn from the seed-bed. ANGELICA, sow, or plant, e., autumn-sown. ALEXANDERS, sow, m. or e. ASPARAGUS, sow or plant, e.; and dress off out-door beds; attend to that in forcing, water with liquid-manure once a week. ARTICHOKEs and BALM, plant. BASIL, sow a little for early use. BEANS, plant; and earth-stir growing crops. BEET (Red), sow a little for early use. BORAGE, sow, and earth-stir autumn-sown, and thin out. BORECOLE, sow, m. BROCCOLI, sow a little of the early kinds, and mark any favorite kinds for seed. BURNER, plant or sow. CAUCHAGES.—Any early kinds may be sown, or *Red Dutch*, should plants be wanted. CARPSICUMS, sow, to forward in hotbed, b. CARROTS, sow, e., for first crop. CARRAWAY, sow. CABBOTS, sow for early crops; attend to thinning-out these in growth, and earth-stirring; sowings of the Early Horn may still be made on gentle hotbeds. CAULIFLOWERS, plant out the winter-protected; attend to spring-sown, as to airing, pricking-out, and earth-stirring; also assist the early hand-glass crop with soakings of liquid-manure, &c.; and sow in succession, e. CELERIAC, sow. CELERY, sow main crop, m., and prick out early-sown on gentle hotbed; leave for seed. CHAMOMILE, plant. CHERVIL, sow; save seed from autumn sown. CHIVES may be divided, and planted out. CLARY, sow, e. CRESS (American), sow. COMPOSTS, prepare. CORIANDER, sow. CORN SALAD, sow. CUCUMBERS, ridge out; pot off; or sow in succession; sow also toward the middle of the month, for planting-out under the hand-glasses next month; attend to those in bearing; keep up a good moist heat. DILL, sow or plant. EARTH-STIRRING, attend to in all cases, and often. FENNEL, sow or plant. GARLIC, finish planting. HOEING, attend to in dry days. HORSEROUND, plant or sow. HORSE RADISH, finish planting. HYSOP, sow, or take up and divide old roots. JERUSALEM ARTICHOKEs, finish planting. KIDNEY-BEANS, sow in succession; attend to those in bearing, assist them with liquid-manure. LEEKS, sow. LETTUCES, sow; prick out; and plant out. MARGOLD, sow. SWEET or KNOTTED MARJORAM, sow a little for early use. MARJORAM (Common Garden), divide and plant out. MELONS, sow in succession, and ridge out; attend to earthing-up, training, &c., the early crops. MINT, plant. MUSHROOM-BEDS, make, and attend to; assist old beds with a little tepid manure water. MUSTARD and CRESS, sow, once or twice a week. NASTURTIUMS, sow, e. ONIONS, sow the main crop; plant for seed, b.; also finish planting the *Underground* or *Potato Onion*; also the *Tree Onion*; and look over those in the store. ORACH, sow. PARSLEY, both kinds, sow. PARSNIPS, sow, b. PEAS, sow in succession; the beginning of this month, is a good season to sow any of the tall kinds; earth-stir, or earth-up, and attend to sticking, &c. PENNYROYAL, plant. POTATOES, finish planting, either in hotbed or open quarter. RADISHES, sow in succession; attend to thinning-out young crops. RAMPION, sow. RAPE, sow common, and edible-rooted, e. RHUBARB, sow or plant, b. ROSEMARY and ROSEMARY, plant. RUE, plant. SAGE, plant. SHALLOTS, finish planting. SALSIFY and SCORZONERA, sow a little for early use. SAVOYS, sow. SEAKALE, sow or plant out; attend to early covering-up, to exclude the light from the crowns, for successional and late crops. SKIRRETS, sow, e. SUCCORY, sow. SORREL, plant or sow. SPINACH, sow in succession. TANSEY and TARRAGON, plant. THYME, sow or plant. TOMATOES, sow in hotbed, e. TURNIPS, make a small sowing two or three times during the month.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 49° and 32.2° respectively. The greatest heat, 66°, occurred on the 8th in 1826; and the lowest cold, 13°, on the 6th in 1845. During the period 122 days were fine, and on 67 rain fell.

NEW PLANTS.

CEROPEGIA THWAITESII (*Mr. Thwaites's Ceropegia*).

THE name of the genus, derived from *keros*, wax, and *pege*, a fountain, refers to the waxy appearance and form of the flower, for although in the above sketch the flowers appear unexpanded, yet they never become more opened, but retain this fountain-head form. The specific name is in honour of Mr. Thwaites, who sent the plant, in 1851, from Ceylon to Kew. They belong to the Natural Order *Asclepiads*, and to *Pentandria Digynia* of Linnæus. It is not unlike *Ceropegia bulbosa*, as we remember seeing it growing in India. It flowered at Kew in September, 1853. The plant is a twiner; the young stem and leaves are frequently tinged with red; calyx of five sepals, green tinged with red; corolla with yellow tube funnel-shaped, "very narrow below the middle, much inflated, and almost globose at the base, dilated upwards, and there sprinkled with dark, blood-red spots." The root of *C. bulbosa* is solid and eatable. It is a native of the Coromandel coast, and is, called by the natives *Manchy-Mandu*.—(*Botanical Magazine*, t. 4758.)

It has been often noted that the world must be circumnavigated before a washerwoman can be comfortably at breakfast with tea and sugar in her caddy; and now it is a truth as strange, that Cape Horn must be doubled twice before Scotch farmers can excel in Wheat crops. Never was a "truth stranger than fiction" more strange than the truth, that those farmers now depend, in a great measure, for such crops, upon the manure made by sea-birds on the furthest—most western—coast of South America.

When Pizarro first conquered the country of the Incas, he found the Peruvians using that manure as a

PASSIFLORA MEDUSEA (*Medusean Passion-flower*).

Believed to be from Mexico. It is a climber, and blooms in November, when trained along the rafter of a stove. Leaves crescent-shaped, with two rows of yellow pellucid glands, from the leaf-stalk towards the concave edge of the leaf. Calyx pale yellow green; the filamentous crown pale crimson. Flowers rather small.—(*Botanical Magazine*, t. 4752.)

CIRRHOPETALUM CORNUTUM (*Horn-bearing Cirrhopetalum*).

This Orchid is a native of the Khasya Hills of eastern Bengal, and bloomed at Kew in the September of 1853. Flowers in a radiating umbel. Upper sepals yellowish, sprinkled with purple; lower ones purplish, and united so as to resemble a horn. Odour like "that of bad glue."—(*Botanical Magazine*, t. 4753.)

COLEUS BLUMEI (*Blume's Coleus*).

This is a Melissa or Balm-like plant, chiefly remarkable for the leaves, all but their green margins being of a dark crimson or blood colour. The plant was sent by Mr. Low, of the Clapton Nursery, to Kew Gardens. The flowers, purple and white, are in long, upright clusters or racemes. It is a native of Java. Sir W. Hooker says:—"Nothing is more easily cultivated, and no stove should be without it, for it flowers throughout the summer, and till the setting in of the winter." It belongs to the Natural Order of *Lipworts*, and to *Didymia Gymnospermia* of Linnæus.—(*Botanical Magazine*, t. 4754.)

DENDROBIUM CYMBIDIODES (*Cymbidium-like Dendrobium*).

This Orchid is the *Desmotrichum cymbidioides* of Blume, but that genus has been incorporated with *Dendrobium*. "Native of the lofty wooded mountains of Gede Salak, in Java." Sepals and petals yellow, labellum white, sprinkled near the base with purple.—(*Botanical Magazine*, t. 4755.)

BILLBERGIA THYRSOIDEA (*Dense-flowered Billbergia*).

This Pine-applewort is a native of rocky places near Rio Janeiro. It was sent to the Kew Gardens by Messrs. Henderson, of the Nursery, St. John's Wood. It has erect, prickly-edged leaves two feet long. The flowers are crimson, and in a very dense bunch or thyrse, and its size and beauty are increased by the bractes being of the same colour, and descending some distance down the flower-stem. It is a stove plant, and flowered at Kew in the November of 1853.—(*Botanical Magazine*, t. 4756.)

fertiliser, and among the thoughts which never crossed his brain most certainly were the facts, that some three centuries after, instead of Peru being the land of gold, she would derive a chief portion of her revenue from that dung of the sea-birds! Yet such a fact is only one more illustration of the truth, that all which appertains to the cultivation of the soil is a more enduring source of wealth than the veins of gold which may traverse its substrata.

That our agriculture has greatly benefited by the use of *Guano*, this "dung of the sea-birds," requires no further proofs than are afforded by the deputation of the

Royal Agricultural Society which waited upon the Secretary of State for Foreign Affairs; and the motion made in the House of Commons, by Colonel Blair, during the past month, urging upon our Government the importance of obtaining this manure at a cheaper rate from the rulers of Peru. In the course of his speech, Colonel Blair stated, that Guano was almost indispensable to Scottish farmers; and the supply of it being at a reasonable rate, affected, to a considerable extent, the food of the people: "upwards of ten million bushels of Wheat being, it was said, added to the produce of the country by means of this stimulant of the soil."

Now, we confess that we are not of the number of those who are anxious to procure Guano from Peru, because the more difficulties there are thrown in the way of procuring it, and the more costly it remains, by so much the more will the science and perseverance of our countrymen be excited to contrive for it an efficient substitute. If that science and perseverance are so directed and stimulated, as Mr. Slaney said at the last meeting of the Royal Agricultural Society, we have "no doubt that the time is gradually approaching when such a substitute for Guano will be found within our own resources as will render us independent of a foreign importation."

Guano is nothing more than the remains of fish after they have passed through the digestive organs of birds; and we have not the shadow of a doubt that, from the refuse of our fisheries, including those of the Sprat, Herring, Pilchard, Whale, Seal, Cod, &c., a manure may be prepared identical in fertilizing effects with Guano.

We are confirmed in that opinion by the chemical researches of Dr. Apjohn, communicated to the Royal Agricultural Improvement Society of Ireland. He analysed the "Fish Manure" of Mr. Petit, and he found it composed as follows:

Water, expelled by a heat of 212°	8.00
Sand33
Oil	2.40
Organic Matter	50.72
Superphosphate of Lime	9.85
Sulphate of Lime, hydrated	19.61
Sulphate of Magnesia71
Sulphate of Potash	2.05
Sulphate of Soda	2.42
Chloride of Sodium	1.12
Sulphate of Ammonia	2.72

100.

This is a very close approximation to Peruvian Guano, and Dr. Apjohn shews that if this is worth £8 : 4 : 1 per ton, then Petit's "Fish Manure" is worth £6 for the same weight.

Pursuing his observations upon "Fish Manure," he observes:

"If a fish of any kind be subjected to an accurate chemical examination, it will be found to consist of water, oil, and azotized organic matter; and associated with this latter, particularly in the bony parts, will be found certain mineral salts, which may be insulated by calcination, and the aggregate of which constitute the calc or ash. Now, in connexion with the process of Mr. Petit, it is obviously important to know the per centage quantities of these different constituents; and, as far as my information extends, the know-

ledge already acquired on this subject is very limited—the only analysis which I have been able to meet with, being one of sprats, by Professor Way, published in Morton's "Encyclopædia of Agriculture," and one of herrings, due to Mr. Sullivan, of this city, and given in an article of his, headed "The Undeveloped Resources of Ireland," which occurs in the first number of a monthly periodical, brought out under the title of "The Journal of Industrial Progress."

"I here subjoin the results obtained by these chemists, The numbers for the sprats being the means of results obtained in 1847 and 1848.

	WAY.		SULLIVAN.	
	Fresh Sprats.	Dry Sprats.	Fresh Herrings.	Dry Herrings.
Water	61.12	—	67.44	—
Oil	19.05	53.09	13.77	42.28
Azotized matter	14.72	41.02	16.39	50.33
Ash	2.11	5.89	2.40	7.39
	100	100	100	100
Per centage of nitrogen	1.94	5.40	2.77	8.05

"The per centages of nitrogen—viz., 11.53 and 14.74, given by Professors Way and Sullivan, have reference, not to the dried fish, but to what Way calls dry nitrogenous matter, i.e., the dried fish minus the oil; and they are, therefore, not found in this table.

"Professor Way also gives the analysis of the ash, which is in the main composed of the phosphates of lime and potash, with alkaline chlorides, and traces of magnesia and iron, and is remarkable for containing no carbonic, and but a minute quantity of sulphuric acid.

"Before I had seen these analyses, being under the impression that sprats and herrings be the fish most likely to be used in the preparation of fish guano, I had resolved to make them the subject of a chemical examination, but was not at the time (about the 16th of last January) able to obtain specimens of either in the Dublin market. I thought however, it would not be uninteresting to experiment upon some other varieties of fish, and I accordingly selected for this purpose a haddock and whiting of small size, which gave the following results. The haddock weighed 11.6, and the whiting 10.2 ounces.

	HADDOCK.		WHITING.	
	Fresh.	Dry.	Fresh.	Dry.
Water	74.33	—	76.18	—
Oil	1.15	4.48	2.34	9.20
Azotised matter	19.35	77.70	17.74	71.50
Oil	4.57	17.82	3.74	15.70
	100	100	100	100
Per centage of nitrogen	Fresh. 3.53	Dry. 13.76	Fresh. 3.43	Dry. 14.43

"The analysis of the ash is not as yet completed.

"Upon comparing these analyses with each other, the haddock and whiting are found to have very much the same composition, the principal difference being that the latter contains better than twice as much oil as occurs in the former. But when they are compared with those of Way and Sullivan, the discrepancies are very great indeed. We find, for example, the amount of water in haddock and whiting to be about ten per cent. greater than in sprats or herrings, their per centage of oil to be in comparison quite trifling, and the amount of their azotized matter and ash to be considerably higher. Lastly, the amount of nitrogen found by Sullivan and Way is greatly less than has been yielded by my experiments—a circumstance easily understood when we bear in mind the very large relative quantity of oil in herrings, and particularly in sprats. This latter being a point of great consequence in relation to the manu-

facture we have under discussion, it will be well to illustrate it by collecting into a table some of the preceding figures.

Fresh sprat 1.94	Dried sprat 5.40	Deprived of oil and dried sprats 11.53
Do. herring 2.77	Do. herring 8.50	Do. do. herrings 14.74
Do. haddock 3.53	Do. haddock 13.76	Do. do. haddock 14.40
Do. whiting 3.43	Do. whiting 14.43	Do. do. whiting 15.82

"We have now sufficient data for investigating the important practical question to which reference has been already made—viz., the number of tons of fresh sprats, herrings, haddock, or whiting, necessary for giving a single ton of Petit's guano. This question may be solved in more ways than one; but the simplest, and I believe the most accurate, will be to divide 10.13, the per centage of nitrogen in the fish guano, as determined by my analysis, by the number which represents the per centage of nitrogen in the fresh fish; the quotient will obviously represent how many tons of the latter will be necessary to yield one of the former. The following are the results of this arithmetical operation:—

In the case of sprats ..	$\frac{10.13}{1.94} = 5.22$
herrings ..	$\frac{10.13}{2.77} = 3.65$
haddock ..	$\frac{10.13}{3.53} = 2.87$
whiting ..	$\frac{10.13}{3.43} = 2.95$

"It thus appears that one ton of our fish guano will require for its production 5.22 tons of sprats, 3.65 of herrings, 2.87 of haddock, and 2.95 of whiting. I may observe, too, that these numbers must be not over, but a little under the mark; for in Petit's process, the fish, I understand, is partially dried in a centrifugal machine, and if so, the liquids squeezed out must contain some proportion of azote."

We desire to draw especial attention to the fact that Dr. Apjohn, and all other modern men of science, found their estimate of the value of a manure upon the amount of ammonia or of nitrogen—the basis of ammonia—which it contains. This view of the value of manures was published by the writer of these remarks nearly thirty years ago, in Loudon's *Gardener's Magazine*, but we note this, not for the purpose of saying "that's my thunder," but for the sake of pointing out the far more important fact, that all are agreed in the estimate of the great fertilizing power of ammonia.

It has been shewn, that on the roof of an ordinary house enough rain and snow fall in the course of twelvemonths to supply, if properly preserved, all its inmates with water during that period. So we are quite sure that the refuse and sewage of those inmates, if properly accumulated, are sufficient to manure the ground necessary to supply them with vegetable food.

This is no merely theoretical view, but is founded upon well-ascertained facts. If all the bones of the butcher's meat are broken into very small pieces, and thrown into a tank, and mixed with the vegetable refuse of the garden, or allotment, and all the coal-ashes; and if in another tank are collected all the house-sewage, including that from the sink, and the water-closet—an ample supply of manure will be furnished for fertilizing the ground required to grow Wheat and garden vegetables for the family; for it must be remembered, that the sewage-manure must be applied in a liquid form; and before being applied to

the growing crops it must be diluted with at least five times its bulk of water.

Of the value of such manure no practical cultivator of the soil needs any testimony. It is most rich in ammonia, and is, in truth, too powerful to be used unless weakened in the way we have named. For those who may need further evidence, we quote the following from the Proceedings of the Royal Agricultural Improvement Society of Ireland, on the 7th of February last:—

"The Chairman (Lord Clonbrock) then rose and said, I should like to take this opportunity of producing to this meeting another sort of manure which I had the means of partially testing myself. It is one that is made by the London Manure Company, and is called "urate." I believe the learned professor, in his analyses, says, that *urate* is not a very accurate name for it, but "will not a rose by any other name smell just as sweet?" so call it what we will, I have proved it to be a very useful and valuable manure. I took it at first by the recommendations of some practical agriculturist in my own neighbourhood, who, having tested it, recommended it to my notice, and I sent a certain quantity to Dr. Apjohn, to be analyzed, and the result was, that I was a little alarmed at the time, for I was afraid it was a poor manure, but I merely read the result of the learned Professor's analyses, without estimating the details of the analyzed itself. Not being a chemist myself, I did not understand the actual value; however, I was determined to give the thing a fair and accurate trial, although, from my analyses, I was afraid I had got an inferior commodity, for we know very well that we are in the habit of being recommended to use manures which often turn out very worthless. I caused twelve drills, therefore, to be opened, one half of which I dressed with Peruvian guano, from Messrs. Gibbs, of first-rate quality, at the rate of four cwt. to the acre; I thought with my new manure the best way would be to put in a quantity which was an equivalent value to the value or price of the Peruvian guano, and I was very much astonished and agreeably surprised at the result, and my turnips got up sooner, and my crop weighed considerably more than the crop raised from the guano.

"Mr. Read—I beg to confirm, my lord, what you have stated; I did not know anything of the *urate* manure till I received a letter from Mr. Perse, of Galway, requesting I would give it a trial, and let him know the result. I did this last autumn when I was late with some green crops. He sent me a ton of it, and I applied it in the proportion you have mentioned—six hundred weight to the acre—and the result was quite beyond my expectations. The crop is beyond an average crop, greater than I have ever been able to grow with Peruvian guano, and it will be a very profitable investment at £7 15s a ton. It was coarse moor land where I tried it, and I thought it would be a failure on such land, but, as I had no other manure for the ground, I ventured on it, and the result was extraordinary. I have rape now growing one-and-a-half-feet high, which was not sown till very late, indeed, in the month of August.

"The Chairman—I have tried it with rape exactly in the same way. I tried it also with rape and bones, but in alternate drills. The bones produced comparatively nothing, while, with the *urate*, the rape was good. I tried the *urate*, also, on oats last year, and no one could go into the field without seeing the improvement at a distance. I have no doubt of its very great value as a manure.

"The analyses of the *urate* is in our journal, but I think, as I said before, to the unlearned reader that analyses would rather disappoint him; at least it did me, and, perhaps, it may other people. If Dr. Apjohn will say a few words on it, perhaps it would answer the same purpose as if it were analyzed again. He will explain to the meeting how it is that it is valuable.

"Dr. Apjohn—With respect to its being valuable, it requires very little corroboration on my part. I had never any doubt that it was a good manure. It contains phosphate of lime, four per cent. superphosphate, and three per cent. of ammonia, and any mixture containing these con-

stituents must be a good manure. The nitrogen, I may observe, is in a state in which it is very easily developed into ammonia, by putrefaction, and in this particular it differs from bones. I recollect stating in my report it was not properly called *urate*. I made that statement on these grounds, that, if an *urate*, it should have contained a large quantity of gypsum, but that such was not the case. There was a little gypsum, but merely the equivalent of the superphosphate present in it; the quantity of superphosphate of lime was small, and the quantity of ammonia was small also, but then it should be recollected that there is no superphosphate at all in Peruvian guano. I can, therefore, easily conceive that this so called *urate* would be productive, in the case of green crops requiring superphosphate, of the very best effects."

Now, the Urate of the London Manure Company thus powerfully eulogized is well-known to be compounded from the sewage of the Metropolis.

The anniversary meeting of the Entomological Society was held on the 23rd of January, when the four gentlemen, whose names had been proposed at the ordinary meeting of January for removal were accordingly removed, and Messrs. Stainton, Dallas, F. Smith, and Edward Shepherd, elected in their stead. No change was made in the offices of the President (who holds the Presidentship for two years), Treasurer, and Secretaries. The President delivered an address, for which a vote of thanks was passed, accompanied by a request that it should be published. The great advantages which have accrued to Entomology by the exertions of numerous collectors in foreign regions was especially dwelt upon, together with the necessity for a more liberal encouragement of them than they in general receive.

The ordinary meeting for February was held on the 6th of that month, Edward Newman, Esq., F.R.S., the President, being in the chair. Messrs. Stainton, F. Smith, and Mr. W. Saunders, were nominated by him to be the Vice-Presidents for the ensuing year. The President exhibited specimens of both sexes of a new genus of Moths, sent from South America by Mr. Bates, by whom they had been reared from the Caterpillar, which reside, singly, in curiously-constructed cases, which they bear about with them (like snail shells), and into which they withdraw the head when alarmed. The female is winged. The President proposed for this new genus the name *Saccophora Batesii*, and considered it to be allied to *Psyche*, but it seems to us to be much nearer to *Gastropacha*.

A magnificent collection of Butterflies and Moths, collected in Ceylon, by Mr. E. Layard, was exhibited by that gentleman, by whom many of the species had been reared from the Caterpillar state. The collection is especially rich in small Butterflies, the nocturnal species. We also especially remarked some magnificent species of the restricted genus *Papilio*, as many as eight or ten of which have been reared, and a most lovely hair-streak Butterfly, with long tails to the hind wings, as well as several species of Death Head Moths.

Mr. J. Curtis read a memoir upon the British species

of click Beetles (*Elatridæ*), entering critically into their nomenclature, and describing several new British species. He likewise called attention to their larvæ, which are known under the common name of "wire worms," and are very destructive to vegetation, several species of which he had represented in his memoirs in the Journal of the Royal Agricultural Society. Mr. S. Stevens also exhibited a species of the same family, new to this country, being the *Elater impressus* of Fabricius, which had been taken at Rannock, in Perthshire, by Messrs. Weaver and Foxcroft, whose researches had added so many species, hitherto only found in the north of continental Europe, to our native fauna.

Mr. S. Stevens also exhibited two striking varieties of the Fritillary Butterflies, *Argynnis Euphrosyne*, and *Arg. Paphia*. The former remarkable for having a black fascia across the fore wings, and the latter for having large black blotches on the upper side of the wings. They were both taken near Ipswich, by Mr. Johnson.

Mr. Douglas exhibited a specimen of the common *Phigalia pilosaria*, remarkable for having been taken as early as the 24th of January, late at night, having been attracted to the light of a gas-lamp, at Lee, in Kent. Mr. Douglas further observed, that he had, on a former occasion, observed Moths late at night flying about the lamps where they had not been visible at an earlier period of the evening. He likewise recommended the attention of entomologists to the curious fact, that notwithstanding the severity of the season, he had already found the larvæ of the minute but beautiful Moths forming the genus *Elachista*, forming their burrows in the leaves of different kinds of grasses, so that it was necessary for persons who were anxious to rear them to be on the look-out already for their Caterpillars.

Mr. G. R. Waterhouse directed the attention of the members to the new illustrated work on the Genera of European Beetles, of which the publication, by M. Jacquelin Duval, has been commenced, and which promises to be of great service to the science. Specimens of the coloured plates were exhibited. He likewise made some observations on the generic identity of two groups of exotic Curculionidæ, which had been named *Cherrus* and *Polyphrades*, by the late M. Schonherr.

The Secretary announced that the Council have extended the time for the receipt of Essays in competition for the prizes on the subject of the Mussel Scale of the Apple, &c., to the 30th of December, 1854, and that they offer a similar prize of £5 5s. for an Essay on the Natural History of the Coccus producing the lac dye of commerce, Dr. Royle having kindly offered to furnish to applicants the information on this subject in the possession of the East India Company, and to procure from the resources of the Company, in India, any further particulars that may be required. The Essays to be delivered by the 31st of December, 1855.

PEARS ON QUINCE STOCKS.

I must confess, that, with an earnest desire to offer a little advice on another subject, I am tempted to set aside my design by the excellent observations made by Mr. C. B. Saunders, at p. 285, January 12th of the current year.

Most of your readers may know that Mr. Saunders is a Jersey nurseryman of long standing; and as to evidence concerning Pears, who shall despise Jersey advice, especially if emanating from such a quarter? Mr. Saunders is certainly as unknown to me as I am to him, but his name and position are no secrets to me; and I do confess, that his frank and generous recognition of me as an old labourer in the Pear-garden is a welcome testimonial, inasmuch, as I feel a secret pride in meeting a fellow-labourer in the cause of truth in devious tracks, although, possibly, the parties commenced their journey from very different points of the compass.

I at once return Mr. Saunders the compliment he paid me, "of learning something from my remarks." Indeed, as to myself, I scarcely ever entered a garden, however mean, or read the opinions of another, but I learned something, and many a grey-headed veteran will confess the same. I, however, profess not to review the system of culture laid down by Mr. Saunders, which, (taken as a whole, and considered as referring to the Channel Islands, and, perhaps, our more southern counties), is, doubtless, up to the mark, yet will, I fear, scarcely be found applicable to our northern counties.

My chief business in this paper will be to examine into the Quince stock question, and in doing so, I must, as in duty bound, pay more heed to the general question than to individual opinions; therefore, to those of my old friends with whom I may have the misfortune to differ, I merely say, please to bear with me.

We must not, however, in discussing matters like this, beg one-half the question; it is all very well to say, "where the soil is suitable, &c.," but the great misfortune is to have to grapple with *unsuitable* soils. Certainly, any first-rate gardener, with all appliances, may work wonders, he may make a dry soil moist, a wet soil into a dry one, a poor into a rich one, a tenacious or stubborn soil into one of the utmost pliability. But those who cater for the majority, although occasionally they may, or try to, write up higher principles than thousands have the means of practising, yet must, after all, show to numberless smaller and less ambitious gardeners how they may, without extra cost, attain a respectable amount of success.

I am glad to have my long-formed opinion better confirmed by so able a person as Mr. Saunders. The opinion, that as a ground-work to the extension of the Quince stock, it is absolutely necessary that the soil be adapted to *the Quince itself*, the recognition of this principle, if it be correct, can alone, as a foundation, support a good superstructure. Well, then, this admitted, I would ask those gardeners of great experience, who have conducted matters of this kind in four or five counties in Britain, wide apart, in how many they have seen the Quince thriving to their entire satisfaction on unprepared soil.

As to the free stock; we find Pears, in all quarters, and on soils widely differing, generally thriving as to the principle of growth. I had some of the newest Pears from Mr. Rivers, about four years since, all on the Quince, from which I was led to expect great things, but they have turned out a complete failure. I had selected with a view to enlarge the amount of late or heavy kinds, adapted to inferior climates. They were planted carefully against a wall having an eastern exposure, and the soil prepared in a way, as I thought, adapted to the Quince, but they have not grown a foot since I ob-

tained them, and they look as if they would never cover the wall. A neighbour of mine, a reverend gentleman, who takes a delight in his garden, had several of the newest kinds on the Quince, about the same time, and I have heard him express much disappointment over his little fancy trees. Now the soil, in general, about here, is rather sandy, and in the two cases I have quoted the subsoil is dry, doubtless too dry; and I think it just to mention all these little things, inasmuch as my object is by no means to lessen the desire for the Quince, but merely to sharpen people's wits, and to make them proceed with caution, in order to lessen the chances of future disappointment, and to lead to the possibility of one day placing the question on a sure and well-ascertained foundation. I doubt not that Mr. Saunders, whose urbane style is, I think, unmistakeable, will excuse my thus handling the Quince rather roughly, and for proceeding a little further with this most interesting, although perplexing question. Mr. Saunders quotes Cornwall, Devon, Somerset, Hants, Essex, Suffolk, as likely counties for the Quince: a goodly array of warm quarters, to be sure; but then, what are they to all the remaining counties in England; to say nothing at all, for the present, of Scotland or Ireland; for folks there love a mellow Pear, and have ad desire to enjoy the product of *their own little gardens*.

I have, for years, urged the importance of soils of an alluvial character; and that if not so, that character must be imitated, if success is expected. Here I find, with much pleasure, Mr. Saunders and I meet; he says, — "*Very dry soils, in high situations, will not suit.*" Now this, if confessed, at once points to the severity of limits imposed on the Quince stock, or to such highly artistic and expensive proceedings as will ill suit the general conditions under which the thousands of small gardeners scattered over the kingdom are placed. And if so, how is it that our great nurserymen, who have made a good thing of the Pear propagation, never informed their customers of so great a fact?

Mr. Saunders speaks of using sea-sand, lime, and salt, in a compost for Pears on the Quince. I have little doubt that the advice is judicious, as regards the sea-sand and lime, and probably it has been found wholesome practice with our friends of the little isles, who, having such things at command, and close at hand, have doubtless tried them repeatedly. Moreover, I have ever found that the Quince thrives best in a soil that is close and fine in texture; in fact, in one that would be called, by old practitioners, unctious: a broad term, to be sure, for our adhesive loams will fall under this head. It is not, however, a matter of loams, for loam alone may not settle this question. There is a character of soil, well known to gardeners, of a darkish, fatty character, that is somewhat moist in almost all weathers, and yet not wet, which is rich in some kind of humus or organic matter, and which, indeed, our Johnstons, Ways, or other celebrated agricultural chemists would better define than I can. This kind, I say, is the thing, in my opinion, for the Quince. I do not say that it is the only kind in which the Quince will thrive; I know better; but it is the kind of compost that I would advise those who are highly interested in the question to imitate; and if the subsoil, at about a couple of feet below the ground level, possesses a permanency of moisture, not wet, why, I verily believe that all the conditions requisite for the Pear on the Quince are present; the climate over-head being tolerably propitious or improved by a well-judged assiduity.

But now, I must just beg to take another glimpse at Mr. Saunders' most interesting paper, one which is, indeed, highly suggestive. Mr. Saunders heads rather low on the stock in order to plant low; and others call into action the fibres from the graft or bud, as well as the roots of the Quince; for, as he justly observes, such a course

will cause fibres to protrude. About the propriety of this, under the circumstances Mr. Saunders quotes, I have not the slightest doubt; but is not this almost tantamount to expressing a doubt about the powers of the Quince stock? I now fear that I have an unpleasant duty to perform, and that is to say, that I must disagree with Mr. Saunders, when he says, p. 285, "All the varieties do not do equally well on Quince bottoms, but the exceptions are very few."

This affirmation, I have little doubt, will be found correct as to Jersey, Guernsey, and the southern counties of England, but surely this is taking too narrow ground for the whole question.

Mr. Saunders fully recognises, in the case of the Quince stock, the immense utility of top-dressings, or, in other words, the encroachment of surface-roots. Our readers, who have been acquainted with THE COTTAGE GARDENER from its earlier period, will, doubtless, remember, that in all the advice I have been called upon to offer, as to hardy fruit culture, I have ever persisted in the propriety of encouraging surface-roots by a *systematic* and *periodical* procedure; and I have had my vanity (I may call it) gratified, by observing the idea echoed by most of our Calendar men, and by writers of what are commonly termed "original articles." The remainder of Mr. Saunders' excellent paper is of so suggestive a character, that some long evening I must beg to have another sitting with it; indeed, we are but on the threshold of this interesting question.

R. ERRINGTON.

SPRING PROPAGATION.

I ENTER on these—the first lessons in gardening—with all the enthusiasm of a young volunteer, although I have been pressed into the service, and, like all other enthusiasts, I shall be liable to overshoot the mark, or hit so low down that I shall miss my aim both ways in my hurry. It is not learning, or knowledge, or philosophy, and all that, which is so much needed, when you want to teach plain, common things, as the knack of doing it so as to be easily understood by those who have only plain, common sense, in the absence of all practice, to help them to learn from what you say or write. They send wise men to parliament, and yet members are constantly asking questions as to how things are to be done, or to be brought forward, that they may steer their course accordingly. Here it is exactly the same; we want questions to be put to us about every thing we write which is not clearly understood; we, also, want questions about things which we pass over; and we want questions relating to things which we forget to write about altogether, or but very seldom. Now, we do receive such questions, in great numbers, every week—that branch is very expensive on account of them, and one would suppose there could not be a more easy way of learning and teaching; yet it is far from it; there is not one in ten who can ask a legal question, or a question on any branch of business, with which he is totally unacquainted, that can be understood by a lawyer, or any other man of business, so as to be able to give a professional answer to it; and our branch seems to be more difficult still, for we hardly find one in twenty of our correspondents whose questions we can make anything of except by mere guessing. For all that, I wish to be reminded of every letter of the alphabet of gardening which I may pass over, or mumble about so as not to be clearly understood by all my readers.

MAKING CUTTINGS is one of the easiest things in gardening. Anybody can make cuttings after one or two lessons. In the first lesson, at page 377, we see that the *young growth* of the tops, of side-shoots are the best

for cuttings of all soft-wooded plants, and that *all tops* are equally good, if they are not very strong and succulent; that two inches is the very longest that these cuttings should be, except Geraniums, and that half-an-inch is long enough for many of them, as dwarf Lobelias, for instance, if one can handle them; that all cuttings of this class are best made by a clean cut across under a joint made on the nail of the left thumb, as we used to cut the nib of a quill-pen; that the pots called "large No. 60," which are rather more than three inches across at the top, are the best size, but that a cutting-pot can never be too small; that the smallest pot is large enough for ten or a dozen of cuttings of *Lobelia compacta*; that such very small cutting-pots, and all cutting-pots, are best inside another pot one size larger, whether they are for bell glasses or not; that all cuttings are best to be quite close to the sides of the pot all round, and no more, but that a clever man, and a more clever woman, would strike every one of them, though the pot was as full of them as they could stick together; that half sand and half peat, or two parts of sand, and one part of leaf-mould, rubbed well together, make one of the best composts for all soft-wooded cuttings, without exception, including bedding Geraniums and Fuchsias; that this compost should not be pressed, for such cuttings, harder than the mould in potting a Geranium; and that a thin layer of white sand makes a cutting-pot look tidy, besides being of great use in taking the water better than peat and sand, and also keeping off mouldiness; that the pot should be nearly full, and if that was too troublesome to water, that the centre of the pot, or rather the sand in the centre, might be made into a hollow on purpose to take the water. I believe these to be the *bare bones* of that article; and the reasons for the different ways make up the whole animal where it stands. Animals and cuttings want water, and the pots must have a little water before the cuttings are planted; at least, it is safe to do so, but propagators seldom do it if they can help it; they contrive so that the sand and peat, or leaf-mould, or whatever they mix for the cuttings, is just damp enough to hold together while they "put in the cuttings." *Planting* cuttings is an outlandish way of talking; they are always *put in*, no matter where; then, after they are put in, they are well watered with a fine rose-pot; with a good, free drainage, and this sandy compost, in such small pots, it is hardly possible to hurt cuttings with too much water; bottom-heat that would roast a Cucumber will not hurt them if they are double-potted, and if they stand on the surface of the bed, the outer pot keeps the other from drying, so that the sides of the cutting-pot are *always moistish*, and that is just what makes the roots come so soon, and creep down the sides with such evident relish.

So you see, that if the operation is done in this simple way, and the pots and cuttings are kept tidy afterwards, there is really no such danger about a hotbed as one might think; the greatest fear is about the smell of it, as that from hot dung, or a mixture of dung and leaves, or from the linings outside, is a most deadly poison to cuttings and to most plants. I only know the Pine-apple plant as an exception, and that would live and thrive in a steam from hot dung that would kill a house spider, or any of the insect tribe: a fact which gardeners take advantage of to kill the different scaly insects which infest this plant from the cradle in a wild state. There ought to be a small thermometer in every cutting-bed to tell the heat morning and evening; and if there is nothing but cuttings in the bed, the thermometer should never fall, day or night, below 75°, and to be between that and 90° or 95° in the middle of a hot day. When the plants are rooted, potted off, and come to their senses, as it were, we keep them much cooler at night, as they would be in a wild state; but for cuttings,

and all stages of propagation, we are acting artificially, and contrary to the course of nature in every way, and in none more wide than in the matter of heat both for the bottom and top degrees. The centre of a new dung bed is the hottest, and the sides of an old one, which is kept on by hot linings on the outside. One seldom gets the right degree of heat from those beds longer than a few days at a time, but that is no great harm; from 85° to 95° is what I used to prefer at six inches below the surface. A layer of tan is the best thing to put over a cutting-bed, for plunging the pots in, or for keeping down bad smells; sand is the next best; leaf-mould the next best, but it is very liable to be over-run by worms; an old mushroom-bed broken-up, and the small parts kept for surfacing, is a very good substitute for these things. I have used sand for many years exclusively for this work, and, when it is to be had at hand, I would take it before anything I ever saw tried. Our correspondent, in the turf-district, would find sifted turf, kept a little damp, the best possible thing for the surface of a cutting-bed. When the heat is uniform, from 75° to 85°, few cuttings begin to grow before they are rooted; and seeing them make a start is the index to their rooting; but, with a higher degree, many cuttings would seem to grow without making a single root.

When cuttings are put in early in the spring, and a large supply of plants is wanted from a small stock of any given plant, it is not an economical way to remove cuttings as soon as they are rooted, or to have them potted into larger or smaller pots; it is better to allow them to stand as they are, and as soon as they have made a growth sufficient to make another lot of cuttings to cut them all down to one joint from the surface of the pot, still leaving the pots in the bed till another growth comes up a little, then to remove the pots to a more airy place for a week or ten days before the struck plants are repotted; however, when one is at a pinch for any particular plant or kind, I see no fear in leaving the first pot in the cutting frame until three or more crops of cuttings are got from the original ones; this I have done with a thousand pots in my day. I once ran out of a blue *Anagallis* altogether, and had to send two hundred miles for a few cuttings in February; I got only seven little cuttings in a box by post, and from those seven I got some hundreds of plants by a fresh crop from every pot of them as fast as they rooted, and not a pot was moved out of the hottest part of the bed till near the end of April, and I forget how many crops I took from the first pot; but there was a fresh crop every eight or nine days.

I never could find room to pot-off rooted cuttings into single pots before the middle of April, and if I had, I very much doubt the use of it. The safest way, and the less trouble, is, after they are a week or so out of the cutting-bed to shake them out of the first pot, and put four or six of them in the same sized pots with a richer compost, two-thirds leaf-mould, or any light rich stuff, and one-third of sand and peat, or all sand if peat is scarce, and to plunge the pots in heat for another week; after that to remove them to a cooler bed with more air, or what we call the nursing bed; and after a while to divide them again and pot them singly, or, what is better, to plant them in rows across a bed made on purpose for that stage of the work; but, of course, all that is not to be looked for in limited places, but the principle can be kept in view, and applied according to means. In the nurseries, it is best to have every plant in a separate pot as soon as it is rooted, for the market; but in private and small establishments there is a world of trouble in watering so many little pots, even if there was sufficient room for them; and to put a little newly-rooted plant of this class into a large pot would be the same as trying to kill it by inches.

PELARGONIUM CUTTINGS.

It is never a good plan to make cuttings of greenhouse Pelargoniums (*Geraniums*, as they are usually called) in the spring, but one is often tempted to do so, now and then, with a new or very scarce kind, and then only the top of a shoot, here or there, where they came too thick for training properly. There is no general rule for such cuttings as to length; any length that you can fix firm in the cutting-pot, with a little top above the sand, will do up to four inches; but suppose I had a real new and very dear plant, with three shoots to it, just now, I could not expect to make any impression with it next May or June by the flowers, but I might make lots of plants from it, and see the flowers also at the right time, then I would go to work on this wise; I would leave the strongest shoot to flower, and I would take two as short cuttings as I could manage from the other two, put each of them in a thumb-pot with a little loam, leaf-mould, and sand; strike them like *Verbenas*, keep them in the hotbed after they were rooted, and potted into a 3 inch pot till they were five or six inches high, then whip off the tops and make two more cuttings in the same way, and so on till the end of next May, and all this time I would use every bit of new growth which appeared on the original two shoots on the first plant, and by the beginning of May I would even stump down these two shoots for final cuttings, and after the plant flowered I would cut down that shoot also, and being the strongest, it will be as forward next autumn as the other two which were cut a month or six weeks earlier. All this is not to be recommended as good practice; far from it; but it is wonderful what one can do, even in a small way, with a new plant. These spring cuttings ought to be planted out-of-doors early in June, and to be taken up and potted by the end of July, and they would come in bumpers next year.

BEDDING GERANIUMS.—Many of them can only be propagated to advantage in the spring, and four inches is the best length for the cuttings, and the cuttings to be put in half-an-inch deep, the same light compost as for other soft-wooded plants will do equally well for all bedding *Geraniums*, without a single exception. The *Golden Chain* is yet the scarcest of them, and every inch of it will strike now as freely as a *Verbena*; the little shoots may look now as brown and seem as firm as horns, yet these will root with no trouble, and no matter how short they may be, the plant will do all the better if they are all cut close in, say to an inch of the older stem. After this cutting-in, let the old plants be kept rather dry for six weeks, and they will break out again, and do all the better for it; and none of these should ever be kept in pots all the summer. *Touchstone*, a bright scarlet flower, is the next scarcest, and one of the best bedders; a very strong grower, that is not worth a straw if not propagated in spring; summer cuttings of it from the flowering wood, in summer, will never make a bushy plant, as such plants will soon get bare and look bad; they are also not nearly so easy to keep in winter. *Lady Mary Fox*, as good in every respect, and as bad in all details, as the last, and the self-same treatment for both. *Diadematum*, *D. rubescens*, and *D. regium*; after discarding *D. bicolor*; the other three are among the very best bedders, and all of them ought to be propagated in the spring, but they will do from summer and autumn cuttings nearly as well; *Wilmore's Surprise*, the new, large, half-double one, is of this class, a shoot from the old *Diadematum*; but whether it is as good as they, for beds, I cannot tell, having not seen a bed of it yet. All the *Quer-eifolium* breed ought to be propagated in the spring; but, like the *Diadematum*s, they will do from summer cuttings; and four-inch cuttings are the best size. *Unique*—I have always maintained that spring cuttings of

this fine bedder are the best; and have also shown that it will strike in the open air as freely as any of the race, and so has one of our correspondents, a gentleman of great skill in most plants. Two gardeners, from Essex, called on me once, and they almost told me to my face, that it was either a mystery or a farce to say that it could be had from cuttings except in the spring; and this very week, I was in a nursery, where I saw scores of splendid old plants of it lying idle on the stage of a very cold greenhouse; and, although I never saw the owner before, I took the liberty to ask him how he could afford to keep them idle at such a time; and he seemed quite astonished, when I told him that they would root like couch grass, as he always understood this kind could not be rooted but at the end of July, in the open air. He never heard of such a book as THE COTTAGE GARDENER, and he did not take in any of the gardening periodicals or papers, yet he has the best stock of *Unique* and of *Quercifolium superbum* or *coccineum*, that ever I saw in a nursery. Cuttings of the *Unique* should be as short as one can manage to make and fix in the pot, because it is so long between the joints, and those of them from cuttings this spring will hardly be fit for beds next summer. Young plants of this kind grow so rank that they do not flower half so well as old plants, and that may be the reason why it is not seen in every flower-garden in Europe, for of all plants, we have nothing like it in colour. The true way to manage it is this—very short cuttings in February, March, or April, will make plants with short-jointed stems near the pot; the grand secret for keeping plants of it ten years or more, to be single-potted in 48-sized pots, by the middle of May; these pots to be plunged in coal-ashes, or in something, early in June; to let the growth trail on the ground, and to cut them to four or five joints next the pot, in the first week in August, and to make cuttings of every bit of them on the spot; then to put these cuttings in pure sand, or very sandy compost, full in the sun, but to be shaded with some boughs for the first three weeks. If the cuttings are long-jointed, as they are almost sure to be, though not so long as cuttings taken from an open bed, let the plants be potted as deep as to bring down a joint to very near the surface when they are taken up at the end of September. These long-jointed plants to be cut down to the joint next the pot the following February, and to stop or nip off the points from the next growth twice or three times before the end of May.

As soon as the plunged plants have started, after being so cut down, they ought to be unplunged, and the roots that have escaped through the bottom hole of the pot must be cut off, and the pots to stand out in the full sun; this check will cause the whole autumn growth to be close-jointed; and when the tops are taken for cuttings, next February, where can you find more bushy plants?—not in England, I am certain. After that they are fit for the Queen, or for anything; but let us have them planted in a bed, in poor soil, and no *Tom Thumb* that ever was born or propagated will ever excel them in the abundance of flowers, or richness of colour; that is, if you plant them in the right way, and not as some people do, who leave half-a-mile, or too much space between plant and plant: six inches from the branches of one plant to the branches on the next is the right thing; and if there are any branches long enough to train, you are in the wrong box; for this sort will never do well if the shoots are allowed to run long in pots. All of them should come directly from a firm, stalky bottom, after the plants are planted out in May, and the open six-inch spaces between the plants might be planted quite thick with the little annual *Eucarridium grandiflorum*, from a sowing about the middle of April; these would flower while the *Uniques* are filling up with new growth.

All the breed of Scarlet Geraniums may be propagated in the spring, if the stock is needed; and the young plants will do to plant round the outside of the older ones. There is no particular rule about the length of cuttings of these—anything, from three to six or seven inches, will do equally well. The dwarf kinds, as *Tom Thumb*, *Frogmore*, or *Baron Hugel*, will do at three inches, and the strong ones may be as long as one can spare the cuttings. All these young Scarlets are better if potted two-and-two in pots, as, when you plant them out, the two can be pushed a little apart without much disturbance to the ball, and that will be wide enough apart for most of them. All the more bushy old ones ought to be set apart for baskets, or vases, or for windows; and the more low and bushy they are, the better they will look in these conspicuous places. There is no better plant going for a small bed, or for an edging of the kind to a large bed, than *Baron Hugel*—a very dwarf kind, with bright scarlet flowers and a dark horse-shoe leaf, and young plants of it require to be planted thick—not more than six inches apart every way, and there ought to be two rows of it for an edging to tell properly. There is a crimson variety of the old *Variegated Scarlet Geranium*, which makes a fine variety in a flower-garden; and there is a variegated form of the *Prince of Orange*, a much neater plant for an edging than the green one, and it is equally sweet in the leaf; it makes a peculiar edging, because it is a different leaf, and a different tint from all other variegated Geraniums. It deserves to be grown as much as any of that class, and there is the new scarlet, or crimson Ivy-leaf sort, which I noticed at one of the Shows in 1852—a very fine thing for a wall, or to hang down from a basket, or vase. A couple of plants of this one would furnish a dozen good cuttings this spring, which would be time enough for this summer, as they grow fast, and one might soon get a stock of it.

ROSE CUTTINGS.

THE spring is not a good time for cuttings of Roses in the open air, yet I have grown lots of them that way, even from cuttings put in as late as the middle of April; but there is a particular way of making and managing them. All the Chinas, and Tea Roses, all the Bourbons, hybrid Bourbons, and hybrid Perpetuals, with Noisettes, and all the climbing Roses, and a great many of the hybrid Chinas, as *Chenedole*, *Blairii*, *Charles Duval*, &c., will come from spring cuttings, but from all the other classes it is mere chance work at this season. The *China* and *Tea Roses* will do by cutting across a joint where the last growth issued from, if the shoots are of a middling size, and not more than four inches long; they do not like to have the top shortened at this season. All the rest ought to be heeled-cuttings, and as short as they can be had; anything below six inches will do. A heel-cutting is one which is pulled downwards so as to wrench it from the branch; the heel is the part torn off, and if a slip of the bark comes off with it they call it a tail, and this must be cut off from the heel as carefully as a cutting is cut, and if there is any ragged wood to the heel have it off also; but on no account shorten the top in the spring. When looking out for such cuttings, choose those that have begun to grow, or whose buds are much swollen, just the opposite of what you would prefer last October. Then, every one of these buds, top bud and all, you must remove by a very gentle touch with the point of your finger on the point of the bud—without this you will not get one out of ten of them to root, do what you will with them. But I must make the reason clear for you: these buds would burst a long time before any roots came, and by their leaves sucking the juice they would soon deprive the cutting of that which would go to make roots; but if you get them off as gently as I say, you will not disturb other very small

buds which cluster round the bottom of most of the large ones; and before these very small buds have time to swell, the natural force of the season, so to speak, will cause roots to grow. All such cuttings ought to be in little pots of very sandy stuff, pressed rather firm, and the cuttings to be close to the sides of the pot; then plunge all the pots in the ground, so that the rims are just out of sight, and no more; the place to be a shady one, where the sun cannot get at them. In dry, parching weather, sprinkle them with a little water early in the day, and about once-a-week.

Now, at parting, let me urge on you to use pots, and I shall tell you the reason why next time we meet.

D. BEATON.

A FEW HINTS ON THE THEORY AND PRACTICE OF PROPAGATING BY CUTTINGS.

AN amateur lately expressed a desire that I would give a few ideas upon this subject, as applicable to various circumstances similar to a late article on sowing *Pelargonium* or other tender seeds. He wanted to know something about the rationale of rooting cuttings, and the most successful and economical methods to adopt during the spring months. These general matters are always attended with this difficulty, that the very particular which the inquirer may most want may be the very subject that the writer passes over unnoticed. But this is the less to be regretted, when any correspondent may obtain the information he wants, if it is possible to supply it, for the expense of a postage-stamp.

At some other time, though not now, I may have something to say upon our friend Mr. Beaton's theory of pruning, respecting which he so courageously bids defiance. There seems to be a growing feeling that the whole system of Physiology is not the cut-and-dried symmetrical affair that books and doctors represented it to be. Only a few years ago, and they who, like myself, had any doubt of a regular circulation of fluids in plants, of watery unelaborated sap upwards, and of elaborated organisable juice downwards, and that as regular, and by vessels as distinct, as the veins and arteries of the animal system, were, in defiance of all potent facts, sneered at as crotchety septicisms. When such facts come to be noticed and reviewed by men of great continental reputation, a vague idea steals over the mind that some change must be made in the system, as no theory can be of any avail that is not based upon, and in accordance with, general facts.

My belief in the theory that all addition of cellular and vascular tissue *must* proceed downwards, from matter now elaborated by the leaves, or stored up after being elaborated, was somewhat early shaken in attempting to raise plants from cuttings in a hotbed, in which, though I was not very successful in getting roots to come in the soil, yet, owing to the great atmospheric heat and moisture, not only did the upper buds on the cuttings swell and elongate, and throw out roots there, but the very upper points of cuttings, cut over an inch or so beyond the bud, had many of them knobs of cellular matter there formed; and from these, when kept somewhat shaded, roots protruded, and hung down in a pendulous position, while, in two or three cases of *Orange* plant cuttings, some small, leafy appendages appeared in connection with this seemingly cellular matter, but which dwindled away as the buds below began to extend into shoots. Now, although many years have passed since then, I thought that the stimulants of heat and moisture could make exceptions to a generally-received theory; for roots came more freely from top and sides than from the base of the cutting; and as this was not at all a desirable result, nor yet, even, under these circumstances, to be relied upon as a

general one, I drew the inference, that it was unwise and undesirable to stimulate and expand the top of a cutting more than was needful for its healthy action; and this kept in view, young plants will be sturdy in their growth, and not drawn and debilitated.

The mystery of raising plants from cuttings would be lessened did beginners recollect that every perfect bud could, under proper circumstances, be made into a plant as well as a perfect seed. I do not now allude to the process of taking a growing bud from one plant and transferring it to another, as in *Rose-budding*; I allude to raising a new individual from the single bud. This is most generally done with deciduous plants and when in a state of repose—such as the *Vine*, in winter or spring. In this case, a piece of the shoot is left on each side of the bud; the cellular and vascular tissue are thus exposed at each end, as well as the woody fibre. To increase this surface, alike for the absorption of moisture and the expansion of tissue, many take off a thin slice of the bark and alburnum on the side of the cutting opposite the bud. These buds, with from half to one inch of the shoot at each end, are generally fixed firm, horizontally, in a pot of soil, and covered half-an-inch, and placed in a briskish heat; two things here being worth noting—that the stimulants affect all parts of the cutting equally; and then, again, at potting time, it will be found that tissue and roots have been protruded, not from one part continuously, but some at the upper end, some at the lower, and others from the underside opposite the bud—a fact worthy the attention of the physiologist.

We cannot follow this plan with cuttings from *growing* plants, because the bud would rot in the soil. We make the nearest approach to it when, in the case of scarce *Verbenas* and *Calceolarias*, &c., we cut between each joint, fasten the stem in the soil, and leave the buds with part of their leaves above, or, in extreme cases, and, where the buds are opposite, splitting the stem into two. In all such cases, especially when the stem is soft, the base and the split sides should be dried in the shade before inserting them. There are only, comparatively, few things that can be thus managed. Most cuttings require from two to three buds, two being essential; the upper one for the ascending stem of the plant, and the lower one, across the base of which the clean cut is to be made, for the descending roots. There are two reasons why this is generally required. The first is, that at these nodes or joints, where leaves are placed and buds are formed, there is a consequent concentration of vital forces; and the second is, that at these places the stem is harder and more dense than between the joints, and, therefore, when the knife is sharp and the cut clean, less likely to damp or rot at its base. To prevent this latter evil still more, all cuttings, except these of small hardwooded things, such as *Heaths* and *Epacris*, will be benefited by having their bases dried in the shade or the sun, in proportion to their succulence, while the upper part of the cutting is kept moist and shaded. The reasons, why in one case it is recommended to slip off cuttings close to the older stem with a *heel*, and in another to cut through just at the junction of the young and older wood, are, that in the former case you may obtain an accumulation of vital power at the seat of the embryo buds, and in the latter, that from the hardness there may be less danger of damping off.

Now, unlike the case of dormant buds, to which we have alluded, and which, though better to be excited gradually, will yet stand a considerable amount of sudden excitement without great injury, the great rule, in the case of these cuttings taken from growing plants, is *just to keep them healthy*, and take nature and the season of the year for your guide, never giving an additional excitement from extra heat, except communicated

gradually, and that chiefly when the sun is gaining strength, taking care that this excitement should act more upon the part of the cutting in the soil than on the part above it. No greater cause of failure can exist, than at all times, and in all circumstances, transferring cuttings into a hotbed. Many fail to get greenhouse and even bedding plants to strike in summer and autumn from this cause alone. In no case should they have a much higher temperature than the plants stood in until a callus is formed, and the protrusion of tissue has taken place. Nay, many things, in autumn, will strike better when kept cooler, such as being transferred from a south border to a north one. Few things at that time will stand the excitement of extra heat. The sun is losing its force, and vegetation is not expanding, but accumulating for its winter repose, and we must act accordingly, until when callused we excite the cuttings to root when we are in a hurry. Patience given as to time would neutralise many failures. Even in spring the extra heat we give should be something proportionate to the season, and to what the plant formerly enjoyed. When, therefore, we are in a hurry, the best plan is *gradually* to give the plant an extra excitement first. Many things will stand extra heat without this precaution, but many will not; and all will be healthier in consequence. Besides, the extreme of dispatch in rooting, even in spring, is not always the extreme of advantage. I have rooted *Calceolarias*, in March, in fewer days than they required weeks in October, and onwards; but, if they had been struck cooler, they would have required less hardening off, and been less liable to insects and weakly constitutions.

"But how are we to keep a growing cutting healthy, and get it to root, without giving it an exciting stimulus? Will not the light and air rob it of its juices when its severance from the root renders a supply naturally impossible?" Quite right. But how is this extra heat, the stumbling-stone of young propagators, to remedy the evil? Will not the extra heat just stimulate the perspiring processes, and thus *welt* your cuttings; or, if that is prevented by a close atmosphere and shading, will they not become wire drawn and attenuated? I have instanced a Vine-cutting in heat. Take the case of a ripened shoot of a Currant tree inserted in the ground in autumn. If the ground, as a whole, has been warmer than the atmosphere, you will get roots before you get shoots. If you left a bud at the base of the cutting, that would be expanded before those exposed to the atmosphere. If the atmosphere was the warmest, it would be the reverse. Generally, they are so alike in average temperature, that the bursting of the buds and the rooting proceeds almost contemporaneously. But cut off a growing shoot in summer, and place it in a sunny place, and where would it be next morning? But cover it with a glass, give it a moist atmosphere, keep its leaves moist, and shade from bright sunshine; and, by a very round-about way, you would obtain a nice-rooted plant.

Now, with slight differences, the same modes and principles must be adopted with all tender cuttings taken from growing plants. Let us merely mention a few of them. 1. The cutting should be maintained in healthy action; whenever it flags, it will be so much time lost. 2. Increase of temperature, if moderate, will give an additional stimulus to the vital powers; a great rise will debilitate the system, and cause extension upwards instead of downwards. The increased heat should be made to tell chiefly on the base of the cutting. 3. The soil in which cuttings are placed should be firm, and the surface a dampish silver sand, next to impervious to air; or the soil should be rather loose, however the surface be covered, in proportion as the cuttings are hard-stemmed or rather succulent. 4. The sun, by the too rapid fixation of carbon in the cutting, the air and heat, by carrying-off its moisture, would,

if permitted, soon leave a wreck behind; and we, in the first place, keep the cutting in healthy action by neutralizing their influence. We keep it from access to air by means of a frame, or bell-glass; and, if at all tender, most likely by both; and we keep the sun off by shading, or causing its rays to be diffused before reaching it. Then, secondly, we do not merely keep in view that the whole surface of the cutting is a transpiring medium, we make it also an absorbing one, by surrounding it with an atmosphere saturated with vapour, and by frequent dewings of the stem and foliage—a much better plan than frequent soakings of the soil in which the cuttings are placed, and escaping the decomposition of the base ends, often the consequence of these soakings. But, 6thly, if the air is long confined, such as under a bell-glass, and especially if there is the smallest bit of fading leaf, the atmosphere will become impure, and, then, when placed near the glass, though shading from sun be necessary, yet every moment's shade more than the cutting actually requires will act as a drawing and debilitating influence. The best chance of rooting consisting in the cutting absorbing and decomposing for itself fresh organisable matter, which it can only do in light, suggested two practices—the first, after a few days, when bell-glasses were kept close down, tilting them up a little on one side at night, which purified the air, and if conical glasses were used, rendered all the trouble of glass-wiping in the morning a thing of the olden times; and, secondly, keeping the cuttings, whether under glasses or the reverse, at such a distance from the glass that the rays of the sun were too diffused to hurt them before reaching them, while the bother and uncertainty of shading were completely avoided. This idea I received, some seventeen years ago, from Mr. Caie, who, from practising it, was one of the most successful propagators at that time round London. I have acted on it ever since.

At present, I have several lights of cuttings now striking, consisting of *Calceolarias*, *Petunias*, *Verbenas*, &c., that have had nothing in the shape of glasses, more than the glass sash, and have never seen a bit of shading. The cuttings stand fully two feet from the glass at the back, and some sixteen inches in front; and if the sun should continue strong, the cuttings and walls are dewed several times a-day with water from a syringe, the sun thus getting something else to evaporate instead of the juices of the cuttings. I have frequently thus dewed fifty lights with less than a garden pail of water, and yet every leaf was damped. The mode of doing so I have previously described. Then, 7thly, the size of the cutting, and the number of leaves, must just be in proportion to the means you possess for keeping the cutting healthy, and preventing its undue perspiration. In plants with leathery leaves, I have often kept all the leaves, even those at the joint through which the knife passed. But in the case of plants with softish stems, this would be apt to promote damping and rotting off, in which case they should be removed. Cuttings with large leaves also require great care; and all things considered, trouble is lessened when the cuttings are rather small, and the leaves, if many and large, are lessened and shortened. A few small, healthy, whole leaves are important for carrying on the necessary functions of the cuttings.

And, lastly, cuttings at all tender or difficult will strike sooner the nearer the base comes to the drainage, and, better still, to the sides of the pot, as the resistance thus given to the swelling of the cutting causes roots to be produced more quickly. Hence, as a rule, a few cuttings round the sides of a small pot will root faster and be every way more sure than many cuttings across a wide pot, or merely inserted in a bed.

A few words more to meet several inquiries. "Dung-and-leaves-heat is considered, when sweet, essential for spring propagation, as furnishing such a genial atmosphere. I have bottom-heat from hot-water. Should I make a bed above the heating medium to receive these advantages, and when?" Just as you like. Your cuttings will do admirably plunged in sand, ashes, or any thing you like; and by watering your heating medium you can have vapour in abundance, though, except you carefully use manure-water, you will not have such a genial moisture as that proceeding from sweet dung and leaves. But leaving the dung alone you will have at least freedom, comparatively, from one annoyance—the slugs and woodlice that somehow get into almost every bed and pit in an old garden; and you will also escape the unpleasantness of not having the bottom-heat you require, as your heating medium will be next to inoperative if it has to pass first through much depth of compact rotted dung. The cuttings in the sand above the heating medium will not, therefore, strike so fast as in a hotbed of dung, but they will be subject to fewer casualties. With such a place, heated by hot-water, propagation may commence after January.

2. "I am making a bed for propagating numbers of things; the plants being previously excited, when should I commence making the cuttings?" The end of February and the beginning of March will be time enough, as before that you might lose more, from want of air and damping, than you would gain in forwardness.

3. "I want to propagate many things, such as Fuchsias, Geraniums, &c., for my window, when should I begin?" April and May will be soon enough, but if you have bell-glasses you might try a few at the end of March. In your case, with only your window, you must, if you begin early, use your chimney-piece in cold nights. Place the cuttings close to the window in warm, dull days; and two or three feet from the window, or shaded with a thin curtain, when it is sunny.

SCRAPS FROM MY NOTE BOOK.

CHATSWORTH.

By way of variety, it is pleasant and desirable to visit gardens in the depth of winter, though at that season the out-door garden has not many charms; the glass-houses are the more interesting, the contrast and comfort being more seen and felt.

During the late severe snow storm, business called me to visit several places, and at each place I saw something interesting. Many persons, I fear, imagine that gardeners in winter are literally "frozen-out gardeners," and if in a good place have almost a sinecure of it. Before hothouses, forcing-houses, pineries, &c. were built for the enjoyment of the wealthy classes, such a state of ease to the gardener might have taken place, but the case is widely different in our day, even in the deepest and most severe winter. Indeed, he has now to exercise a large share of forethought, and close attention, almost day and night also, to keep out Jack Frost, and to keep a continual look out for choice plants to bloom. He has to put his Vines and Peaches, Cucumbers and Mushrooms, in motion; he has to produce his winter salads, his early Sea-kale and Rhubarb; and a little later in the season he has to prepare thousands, nay, in some places, tens of thousands of bedding-out plants to furnish his flower-beds in the, comparatively-speaking, new massing style; and all this, and a great deal more, he has to perform, study, and bring to bear through all weathers. Truly the gardener's bed is not, in this generation, a bed of roses. These thoughts passed through my mind lately, whilst visiting such places as Chatsworth, Heaton Park, Kinnel Park,

Penrhyn Castle, Haigh Hall, and many others. Any person that has any knowledge of gardening would observe, at this season of the year, busy notes of preparation to bring to bear certain effects hereafter. I often think a good gardener would make a good general; the same train of ideas passes through his mind—he has to combat with numerous enemies, frost, blight, too much wet, too little, too much sun and too little, besides hosts of vermin; all these have to be overcome, rebutted, or destroyed, to insure the victory. Happily, these enemies are not his own species, and therefore he feels the less regret at bringing all his artillery to bear upon them.

At Chatsworth, I saw, in the middle of January, a most remarkable illustration of the art of retardation. At one end of a long range of Vineries there is one house devoted entirely to one variety of the Vine, for the purpose of supplying Grapes in February and March, or, perhaps, still later. The kind is *West's St. Peter's*. The crop was abundant, the bunches, many of them, large, and the berries as black as ink, and as plump as a partridge; finer Grapes need not be. In another house there was hanging a few bunches of fine *Muscats* and *Cannon Hall Grapes*! a rare sight for the 20th of January.

In the Peach-house range the earliest house was just going out of flower, and apparently setting well. In a narrow house some Vines in pots were showing fruit. The back wall has a raised narrow border. In this border the pots containing the Vines were plunged up to their rims in soil. The front Vines were not plunged, and by this method the Grapes ripen in succession; those on the back wall, of course, ripen first, and the others afterwards.

The Cucumber-house was in full bearing. I noted several nice fruit cut, and the cut end set in water. The young man told me that was an excellent way to keep them fresh—a good scrap of information. In a Pine-pit I observed some very fine, well-swelled Pines, of the kind called *Smooth Cayenne*, which I was informed has a good flavour in winter, equal, if not superior, to the *Montserrat*; superior it certainly was, in point of size, at that time.

In the Mushroom-house, which, by-the-by, is a very superior one, was a great quantity of that delicious vegetable. In the floral department, I was much struck with the Victoria-house. Instead of that magnificent plant, the tank was dry and filled with Camellias, Azaleas, and Rhododendrons. There was a change with a vengeance. Let not the reader, however, suppose that it is no longer the Victoria-house. *That plant is now proved, without any doubt, to be an annual*, and therefore perishes in the autumn. Young plants are to be raised early in the spring, and as soon as they are large enough will be removed into the noble Victoria-house, and these temporary inhabitants will be banished into other quarters.

The Orchid-house, as a matter of course, I paid my due respects to, and found it gay with bloom, particularly of the following:—*Ansellia Africana*, two noble plants with numerous spikes; *Calanthe masuca*, two spikes at this (for that plant) uncommon season; *C. vestita*, with many spikes of the deep-coloured spot variety; *Dendrobium heterocarpum*, with its honey-scented pale blossoms; *Lalia anceps*, and its variety *Barkeriana*, many blooms; also the charming *Sophranitis grandiflora*, a tiny plant, with flowers three times its size; *S. violacea*, a pretty thing in its way; *Barkeria Skinnerii*, the deep-coloured variety; and several species of *Zygopetalum*, the prettiest of which is *crinitum*.

T. APPLEBY.

THE ANTIRRHINUM.

(Continued from page 350.)

A GREAT number of florists' flowers, though exceedingly beautiful, have the disadvantage of their bloom being short lived. Such, for instance, as the glorious, though somewhat gaudy, Tulip, and the neat-blossomed Ranunculus. These, and some others, which the florist will easily recollect, only last, with every attention to shading them from the flower-fading power of the sun, some five or six weeks, but I may fairly claim for the Antirrhinum the power, with very moderate care, of continuing to reward the cultivator with its bright-coloured blossoms for at least three months, and that at a season when florists' flowers are comparatively scarce: even as a bedding-out flower it has great merit. It produces at least three colours not to be surpassed by any flower—I mean bright crimson, pure white, and clear yellow. For large beds, especially, it is well adapted, blooming continuously during July, August, and September. For this purpose I recommend it to Mr. Beaton, and should be glad if he would give his opinion on its capability and merits.

Then, again, it is very well adapted to plant on rockwork. I have seen admirable specimens grown in such a situation. I have noticed, also, very pretty plants of it growing on old brick walls flowering very freely, and giving an interest to what would, without them, have been most unsightly objects.

I trust I have said enough in favour of this flower to induce the readers of THE COTTAGE GARDENER to cultivate it more than they have hitherto done; and in order that such as have not yet grown it, or but imperfectly so, may succeed, I shall endeavour to describe the best way of cultivating it.

Propagation: by Seed, to obtain improved varieties.—The Antirrhinum is so perfectly hardy that the seed may be sown in the open border of the garden. I would advise the zealous raiser of improved varieties first to procure from some respectable florist a few of the leading best sorts now in cultivation, grow them one year, and save seeds from them, keeping the seed of each variety to itself. By adopting this plan he would find out the best breeders. There is no seed like home-saved. I have before me, now, a letter from a gentleman near Liverpool, containing an unlimited order for any kind of florists' flower-seed, provided I could warrant it being gathered from distinct varieties kept separate; meaning, for instance, seed saved from *Cineraria Henderson's Marianne*, or *Calceolaria Sultan*, or *Hollyhock Cream of the Valley*, or *Fuchsia Bank's Glory*, &c. Every seedsman throughout the length and breadth of the land knows that flower seeds are not saved separately from separate varieties, but I do think the idea such an order implies is worthy of being carried out. Packets of so saved seeds would certainly sell, and there would be more probability of the purchaser obtaining improved varieties from such seed. It is the consideration arising from my customer's order that leads me to recommend the keeping the different varieties of Antirrhinum seed in separate parcels, and the probability of obtaining improved distinct varieties would be increased, if the different sorts were grown at a distance from each other, the seeds kept in separate paper, named, and sown in separate parcels. It may appear tedious such a process, but trouble is nothing compared with success.

The time for sowing this carefully-saved seed is about the second week in April. Prepare a bed for it in an open part of the garden, by manuring it well in the autumn, and digging in the manure at the same time, leaving the surface rather rough for the frosts to act upon it and pulverize. Then, when the sowing time arrives, fork the surface over, breaking it as fine as pos-

sible. Choose a time when the surface is moderately dry for this operation. Have a sufficient number of wooden labels ready, rub a little white lead on them, take one, and write legibly the name of the variety from whence the seed was gathered; sow that, and then write the next, and sow it also, and so proceed till all the parcels are sown; then rake the bed smooth to cover the seed, and the operation is finished. Should the weather prove dry afterwards, a very gentle watering during evening, now and then, will help the seeds to vegetate.

When the seedlings have attained an inch or two in height, dig another larger bed, and transplant the seedlings into it, planting them five inches apart every way, keeping the sorts still separate. Here they may remain till they flower. Then compare each, as they come fully into bloom, with the properties as given in my last paper on this subject; and all such as are quite up to, or superior to, the points, give a name to, and describe them in a book kept for that purpose. All the rest that are deficient in form, colour, and size, may either be thrown away at once, or planted in the front of shrubberies, if good in colour; or give them away to any poor cottager to ornament his flower-border. The good, improved sorts should be increased by cuttings; the method of doing which I shall give in my next.

T. APPLEBY.

(To be continued.)

FRUIT TRELLISES.

It would be difficult to say whether the old-fashioned perpendicular Trellis be on the decline or the ascendant. True it is, that some gardens, in which that useful old-fashioned appendage had done duty for some two or three generations, has been summarily dismissed by the present one; yet there are others wherein the time-honoured contrivance has been reinstated in an improved form, and in many gardens it has been adopted in some shape or other, the old-fashioned one retaining many of its features still. Now, it need not be asked what benefits it confers, since we have the testimony of something more than one hundred years to prove its utility, and surely that says more in its favour than the most eloquent eulogy that could be bestowed upon it. I shall, therefore, at once go into the details of the variety of its forms, commencing first of all with that oldest shape, which, after all, is probably the best, that is, taking all things into consideration—I mean the ordinary upright Trellis.

There are various forms of this differing from each other in shape and height, as well as in the material the frame-work is made of, but usually this is wood or iron, or both together. Now, though I am not altogether positive that iron exercises a hurtful influence on the trees planted and trained against it, yet I prefer wood where other reasons do not point out iron as being better adapted. However, as other things often determine this, I need only say, that when it can be contrived to have iron standards and rails, wooden uprights fastened to the iron rails form the best material on which to train trees; to have the whole of timber is attended with after-trouble when the latter decays, which posts are sure to do; but this being a subject in Mr. Errington's province, I dismiss it, and would request the amateur about putting up a Trellis to examine those in his neighbourhood, and, doubtless, he will see a something which will enable him to apply the right means; but if his place be entirely new, I would advise him to wait a year or two before putting it up, in order to get the trees fairly established, and grown a certain length, before he applies such an open and conspicuous piece of cago-work

to his garden so long before it is wanted; the trees must, of course, be trained to sticks thrust in the ground in the mean time; but observe, I do not advocate the last measure on any other account than that of saving the Trellis work, which, by being placed in its position some two or three years before wanted, naturally diminishes its working capabilities the like time.

It seldom happens that the direction of the Trellis can be commanded, as it forms a feature in a garden when it is carried in all directions; but it will be found that those running north and south will be the most useful, as by that both sides enjoy an equal amount of sunshine; this benefit is known to the husbandman as well as the gardener; for in some districts, where it is customary to shock all the corn, they are made so as to point to the one o'clock sun, the attentive agriculturist having found that to be about the middle of the "harvest day;" and so accurately is this accomplished, that in walking over several fields it is seldom that a departure is found from so good a rule. Now, why not fruit-trees benefit as well as corn from an exposure on two sides? consequently, it would be prudent to have trellises covered with fruit trees, and rows of vegetables, especially peas, scarlet runners, &c., planted in such a way as to command these conditions.

I will not here dwell on the kinds of trees proper to plant, but will say, that where tender Pears, Plums, &c., are so trained, they are more easily protected when in bloom than when planted or grown in any other way, as any little sheltering substance thrown over the top is usually sufficient to protect the whole tree; and at such times it is highly advisable to use such a covering as a few mats, an old sheet, or, in fact, anything that can be obtained.

We now come to "the Fancy Trellis," of which there are several varieties; one, a very common one, being a sort of continuous arch, or vault, with a walk underneath; this is very well in some cases, but it is more curious than pretty in long lengths. This is generally composed of iron or wire-work, and to look well ought to be well covered with trees. It has been argued, that by the trees covering so large a space as the arch, a greater quantity of fruit must be obtained than by trees planted and trained the ordinary way; but then it is to be remembered, that those trees have only one side, whereas those planted against an upright Trellis bear on both sides, generally; and the exposure of bloom, in such a position, to the spring frosts and other inclemencies, is greater than that from trees growing in any other way. However, it has its admirers, and may, possibly, be a prudent appendage in some gardens.

Many years ago, I had the management of a Trellis which took my fancy more than any that I have seen since; it was somewhat like one-half of an arch, the walk by the side of it being much lower than the adjoining ground where the trees were planted, a wall formed one verge, and along the top of this wall iron supports were inserted, at intervals, to support the iron frame-work of this Trellis, which, rising on the border, projected a considerable way over the wall, having plenty of head room. Of course, these iron supports had the whole weight to carry, but being placed perpendicularly they had no difficulty in doing so, and the whole presented a pleasing appearance. The top of the wall, instead of having an ornamental coping, was covered with the pretty British plant *Sedum acre* (or stone crop), which deserves more attention than it often gets. This Trellis, I may add, answered the purpose very well, while its adoption in a hilly garden was not only appropriate but highly ornamental.

There are other forms in which the same thing may be effected, as the *Table Trellis*, which is a frame-work, flat, or nearly so, and often but little elevated; this is often placed where it is advisable to train the trees in the opposite

way to the last-named, with their heads up the hill side, whereas, the other being planted on the hill curved from it, covering, or partly covering, a walk on a lower level.

It is needless here to mention the fanciful figures that are now and then introduced into the gardens of the curious, some of them are constrained to take grotesque shapes, with little to recommend them but their singularity, as, for instance, upright cylinders, with the trees trained spirally around them; fantastic globes, semi-globes, or other figures approaching thereto, have all their admirers; but as these are detached figures, rather than a continuous trained object, I must dismiss them, and in winding up this article on Trellises, would beg to remind our young friends of the Raspberry Trellis, which, by its simplicity, may with propriety be adopted everywhere to advantage, as it need only consist of three horizontal rails, with posts where wanted, and the canes, being tied to such rails, will bear fruit of better quality than when huddled together all to one stake in the usual manner. Other things might be similarly treated, but Raspas are the most benefited by it. Another description of Trellis is also often turned to good account, which is one placed on the roof of a house on which a Vine or some other fruit-tree is trained. This, however, is only applicable in certain cases, but where it is, a single year's trial will soon prove how much better the Grapes ripen on the roof facing the mid-day's sun than on the ordinary wall having that aspect; but this subject having been already treated of in *THE COTTAGE GARDENER* need not be repeated here.

J. ROBSON.

ECONOMY OF THE FARM-YARD.

THE economy of the Farm-yard must, certainly, be considered as a subject of the highest importance in connection with agriculture, for under this head has to be noted the method of managing the manure, both as regards its quantity as well as quality, and the maintenance of the fertility of the land must, in a great measure, depend upon the extent and the value of the home-made manure; for although, by the application of capital in the purchase of artificial manures, the land may be made to produce crops greatly in excess of the ordinary modes of management, yet the method of manufacturing manures in the farm-steading is now become part and parcel of the best systems of feeding, and may be considered scientifically in conjunction with the feeding of animals. In almost every portion of the kingdom great improvement in the farm-buildings have been recently effected, yet much remains to be done in different parts of the country, and in many instances, where improvements have been attempted, they cannot be considered much more than mere alterations; for some of the most essential changes required for the making and preservation of Farm-yard manure, have been but too often entirely neglected.

There is a mode of proceeding, on the part of many occupiers of land, which is highly blameable; they do not, in many instances, avail themselves of the advantage of good yards and buildings, for the conversion of their straw, fodder, &c., into manure of the best quality.

I have often noticed, upon large corn-producing farms, immense quantities of straw lying about in a

rotten or partially decayed state, and the number of cattle kept on the farm totally inadequate to convert the straw into a manure worth cartage to the field. And this leads me to one of the most important points in the economy of the Farm-yard. It often happens that a large number of Sheep stock are kept, particularly upon favourable soils, and quite sufficient in number to consume the whole of the root-crops grown, and also the far greater portion of the Hay produced upon the farm. Yet this as a system must be considered, upon the whole, disadvantageous; for the profits of a farm ought to arise from returns in many directions, and a sufficient number of either store, or fattening animals, should always be kept in the farm-steading, to convert the straw produced into valuable manure; and for this purpose, at least twenty-five per cent. of the roots produced should be consumed by cattle, pigs, &c.

There are, however, cases in which exceptions may be allowed—such as heavy land, where it is desirable to remove the whole of the roots from the land; and also in localities where there is an extensive sale for Straw, at a good price, a considerable quantity may then be disposed of and replaced by purchasing artificial manures of the like value with great advantage; this mode of proceeding alone can justify the consuming the whole root-crop by sheep on the land.

The construction of the Farm-yard, the arrangement of the buildings, and the accommodation afforded for the cattle, must now be considered; and as it is too often the case that these are altogether insufficient to give the occupier an opportunity of converting his straw into good manure, I intend to lay down a few general rules for guidance, whereby advantages may be obtained without any reconstruction or costly alteration of the buildings; and I consider this the more necessary, when it is remembered, that it often occurs, from the force of circumstances, that new steadings built upon improved principles cannot be obtained.

First, let every building be spouted, and the water from the roofs carried away to some convenient place, where it cannot gain access to the Farm-yard and deteriorate the accumulating mass of manure. Let the Farm-yard be considered a store, or repository for manure, instead of, as formerly, a place to feed cattle in without shelter; and, previously to depositing manure in the yards, place at the bottom, peat, or loose earth, where such can be obtained, six or eight inches in thickness; this will absorb the drainage from the manure which may accumulate upon it. In placing the manure in the yard, let each kind be spread about the surface in order that a proper admixture may take place; its value will then be equalized in all respects when required for use. I set no value upon a tank to receive the liquid which draws from the open yard; I prefer a rather long and narrow cesspool, kept supplied occasionally with loose earth &c., for the liquid-manure to run into, the sediment from which will be absorbed by the earth &c., which may be removed about twice a-year, and used as manure for pasture and grass land. I beg, however, to say, that in all cases where the Farm-yard

is so situated, the drainage from the manure should be led on to pasture or meadow-land, for the purposes of irrigation, where a sufficient outfall can be obtained to distribute it with regularity.

The next consideration is the accommodation for the animals when not allowed to lie promiscuously in the Farm-yard. My own practice is to allow separate apartments for each, or every set of animals, during the winter months. Thus, the dairy Cows have each a shed to lie in, 12 feet by 10 feet, and space in front of about the same extent; the Heifers, also, are kept two or three together, in a similar shed, but with a rather larger space in front. The breeding Sows have each a shed to rest in, and outer space for eating green food, the same size as the pens for the cows; and each farrow of store, or fattening pigs, are accommodated in the same way.

In each and every instance, the pens are first covered at the bottom with loamy earth, about eight inches in thickness, and the manure is always allowed to accumulate under the animals, upon the principle of box feeding, taking care to litter with straw daily, as cleanliness requires, and the accumulation is allowed to continue until inconvenience arises. The manure is then removed and spread over the farm-yard, or put into heap for more immediate use if required.

As I do not intend these observations to apply to modern or recently-constructed buildings, I would here state, that in case further space is required for fattening cattle, good roomy boxes may be obtained by appropriating the corn mows of a barn; and it often happens, that in ancient farm-steadings much barn room may be dispensed with, and fitted up as cattle boxes at a trifling cost, and may be managed with nearly the same facility and advantage as first-rate buildings.

JOSEPH BLUNDELL.

(To be continued.)

WHAT A MOMENT MAY BRING FORTH.

By the Authoress of "My Flowers."

HERETO, I have sketched the history of persons in the more humble ranks of life as warnings or examples; but I am now going to set forth a warning taken from a higher sphere, to show that the Lord is no respecter of persons, but that His just judgments fall alike on the high and low; and that there is a "woe" "unto them that are mighty to drink wine," as well as beer, and to men of strength to mingle strong drink, "whether they are rich or poor, learned or unlearned; for "the soul that sinneth, it shall die."

We do not so often observe the miserable consequences of sin in the higher walks of life. It is more out of sight than amongst those whose bread depends upon the labour of their hands; but let my cottage readers be quite sure of this, that sin and folly reap as full a reward among the nobles of the land as among the peasants; perhaps even more so; and that many a splendid carriage that dashes by, and many a splendid mansion, where gold and fulness of bread are found, contain hearts as withered, and broken, and mourning, and diseased, as any of those starving in a desolate cottage, or confined within the walls of a union workhouse.

Edward Fortescue was the son of a nobleman. His parents were both devoid of principle, and their manner of life sadly unlike what it ought to be amongst the nobility of

a Christian land. From them he could learn nothing of good; and his youthful years, both at school and college, were wild and dissipated. When he first drew particular notice he was concealing himself, under a feigned name and the appearance of a plain gentleman, from some pursuit or other; and living in a place as much as possible out of the way of former acquaintances. His countenance evidently bore marks of his manner of life; no one who looked at him could avoid seeing that he was a man of confirmed drinking habits; and his conduct soon convinced every one of the fact. It was gradually whispered, however, that he was a disguised nobleman; that his history was a pitiful one; that he had been unjustly treated, obliged to hide from his own father, who wanted to force him into signing away money and lands, and was much to be sympathized with. This drew him into society, where the quiet elegance of his manners would have made him very welcome, but for the habits he indulged in, which were constantly coming to light. Often was he picked up in the streets wholly intoxicated, and sometimes fighting with men of low and wretched character; yet two or three respectable friends clave to him, either, as he used to say "for my five balls" (meaning his future coronet), or because there were kindly qualities buried under the frightful features of his outward life. Alas! what a terrible sight it is to see vice triumphant in high places! To see the young, educated, titled man, a slave in its grasp, and sacrificing all the talents the Lord has given him—station, wealth, power, and influence—to debasing passions, instead of spending them in the service of God and to His glory!

Little did poor Mr. Fortescue dream of the end of his wretched earthly career! Little did those who laughed, and danced, and associated with him, dream of it either! He went on recklessly in the downward path, never attended the means of Grace, or the sound of the Gospel, at least while we were acquainted with him; and if a terror ever crept into his heart he must have drunk it away. Oh! let my readers pause one moment, to think of this manner of using "things temporal!" Is it not *too surely*, to "lose the things that are eternal?"

Years passed away; and Mr. Fortescue still lived on in the same manner, sometimes abroad, sometimes at home; but always under his feigned name, and in his usual wretched habits. He had formed a close intimacy with one family, whose eldest son, though quite unlike him in outward things, had been his great friend from their first introduction, and with this family he passed most of his time, when he was, as he called it, at home.

When about to return from France, for the last time, as it sadly proved, he wrote to his friend to announce his arrival, saying, with a thoughtlessness and presumption only too common with us all, "On that day, without fail, you will see me at your dinner-table." "Go to now, ye that say, To-day, or to-morrow we will go into such a city, and continue there a year, and buy, and sell, and get gain: whereas ye know not what shall be on the morrow. For what is your life? It is even a vapour that appeareth for a little time and then vanisheth away. For that ye ought to say, If the Lord will, we shall live, and do this or that."

Mr. Fortescue took his passage, and had a prosperous waft across the channel. On arriving in the roads, the tide did not quite serve for the little sailing-*packet* to enter the pier, and they tacked once or twice in consequence. Most of the passengers, glad to get out of ship, landed in the boat, but Mr. Fortescue, who was bringing over some valuable articles belonging to a friend, chose to remain with his luggage, and see it safely landed himself. In a very short time the tide served, the little vessel made her last tack, and was entering the mouth of the pier. Surely all was safe and secure! At that very instant of time a sudden chop-round of the breeze took the vessel aback; she struck against the pier, and went down before the eyes of the horrified spectators. Mr. Fortescue could not swim, and perished! The last that was seen of him was as he stood on the deck with his portmanteau in his hand, surprize and horror stamped on his face. No time was allowed for an effort to escape, or he might almost have sprung from the vessel's side to the shore. No time was allowed for more than a full sight of his awful position on the brink of

terrific destruction. Oh! who can describe the horror of that sight—of that unlooked-for, unprepared-for moment!

Thus closed a life of recklessness and open sin. In the very moment that seemed most smooth and safe, destruction came. Who can reckon on a day; an instant? "Be ye ready; for the Son of Man cometh at an hour when ye think not."

Readers—we may all learn a deep lesson. We may not be living, perhaps, in *outward* sin; but we may be quite, quite as unfit to die as this young nobleman. Inward sin is quite as impure in the sight of a holy God as the most desperate outward wickedness; let us remember *that*. The Lord is no respecter of person; there is neither high nor low in His sight. "The soul that sinneth, it shall die." But what a death it is! and how suddenly it may come rushing upon us, just when we are saying, "Peace and safety!" There is *no* peace, there is *no* safety to any but those who are gathered under Almighty wings. Are *we* sheltered there? Have we fled for salvation to Him who died to purchase it for us? We are all trying to walk on the waves of this troublesome world, somehow or other; but we cannot do it long. We *must* sink, if the hand of Jesus Christ is not stretched out to save us. We may think we are just entering the heavenly port; but the breeze of hope will chop right round, readers, and dash us on the rocks, unless Christ is in the ship; unless we have a firm hold of Him; unless He is our Hope and our Salvation. Let this solemn warning rouse us to seek Him while He may be found!

THE POLAND FOWL AS RECENTLY EXHIBITED.

We may fairly assume that custom has now sanctioned the arrangement of all the regular-tufted fowls in the classes assigned to Polands, and, consequently, that the "*tufted Hamburg*" is a designation applicable only to former times. By the expression, "*regular-tufted*" fowls, an exception is provided for in such cases as the Ptarmigan, the Pencilled Game-fowl, and some others, distinguished by a lark-crest totally distinct from the full, globular top-knot of the Poland proper.

The origin of this latter breed being enveloped in so much uncertainty, the advocates of the old combless Pole must not take it amiss if the line of demarcation between their favourites and the birds known to them as "*tufted Hamburgs*" being regarded as the cause of much needless confusion, has been, by almost general consent, and by the authority of our leading Poultry Societies, relinquished and done away with. The argument for this distinction, it would appear, rested mainly on the absence of the comb, and alleged greater size of the "*true Poland*," for in respect of feather, we apprehend, their case has not been established, the Spangled birds alone having thus been termed Hamburgs. Now, with reference to the comb, there can be no doubt that the less of it the better in any Poland fowl, and that anything approaching the huge horns that sometimes disfigure these birds is highly objectionable, as imparting a degree of coarseness to their otherwise symmetrical form. But, at the same time, exhibitors would act prudently to remember, that amputation, or reduction by the knife of this appendage, is an operation always apparent to an experienced eye, and conducting neither to their owner's credit, nor to the appearance of the birds themselves. A cicatriced wound is always left, and the space occupied by the substance removed is never properly filled up by the feathers of the crest.

The *White-crested Black Polands* of 1853 were no improvement on their predecessors, but, rather, as we think, the contrary. Condition was too often absent, even when form and feather were satisfactory. The causes that have probably induced this result may embrace their delicate constitution as chickens, and their comparatively unprofitable character as mere poultry; circumstances which have given a preference to more useful and hardier fowls, few of which, however, in beauty of appearance, can claim superiority over the subjects of these remarks.

The Poland, indeed, and these observations apply equally to all their varieties, has been well styled an "*aviary bird*;"

for although greater extension of limits that would usually be implied by this term are requisite for their appearance in their best form, they are confessedly unable to rough through their existence in the same independent manner that most of our other breeds are capable of doing.

A limited portion of White has not been thought incompatible with the plumage of the White-crested Black Poland cock's tail, and has even, sometimes, been alluded to as instancing purity of blood. But to this we do not assent, considering that any fowl distinctively termed black, or any other colour, should be uniformly of that colour, any deviation, such as is here provided for by the appellation "*White-crested*," being alone excepted; bronze and red markings, in either sex, have been the just cause of many summary disqualifications. Poland "*improvers*," however, have been, of late, as busy with the top-knots, as the combs of other birds, and with precisely the same results—the disfigurement, and ignominious omission of their pens from judicial notice. The Dahlia fancier applies his curling-tongs to the petal of his much-cherished flower, and a tendency to irregularity of form is thus checked, but the abstraction of the offending portion would mar its own object. In the same way, if it is thought that a Poland's top-knot requires cleansing and arrangement in any mode previous to exhibition, no one has a right to object to this, so long as the bird is allowed to retain the full complement of its plumage, although we may gravely doubt the advantage to be thus gained if the bird is in good health; and, if otherwise, it ought not to appear under any circumstances whatever.

Those who are in the habit of thus "plucking" their White-crested Black Polands, would do well to obtain a regulative standard for their labours. As frequently every single black feather has vanished from the anterior portion of the tuft, we should be glad to learn whence their model was obtained, for we have never yet been so fortunate as to meet with any specimen of this variety, where black feathers, more or less in number, were not visible at the base of the top-knot above the nostrils.

Golden Polands have fully maintained their ground, and the fierce discussion of some few months since, "*beards or no beards*," seems, in their case, and with the Silver also, to have gone in favour of the beard. We should be curious, indeed, to learn whether the pros and cons of this knotty point, so ardently and laboriously discussed in the pages of THE COTTAGE GARDENER, influenced in any way the present general desires of the guardians of the public peace, who are now so anxious thus to adorn their chins and throats, and which municipal and magisterial authorities seem so unwilling to permit. What triumph for the advocates of the beard, if human bipeds thus become emulous of the natural comforts of this portion of the feathered race. An elaborate article for the transactions of a learned society must testify to this evidence of the value of poultry literature.

The beard, we repeat, is evidently popular with the exhibitors of the Gold and Silver Polands, and our own individual opinion certainly goes with them. For not merely do we regard the beard as in good keeping with the appearance of the top-knot, but our conclusion, from past exhibitions, would lead us to anticipate more birds of higher merit, in other respects, among any given number of Polands, than we should probably meet with among the unbearded. The main faults in this class, as of old, have been the imperfect character of the spangle; frequently so heavy as to leave little of the ground-colour visible, and nearly as often irregular and spotty. This remark, indeed, applies fully as much to the Silver as the Golden birds. The top-knots of the latter are among the points to which the breeder's attention should be carefully directed, for in the male birds they are seldom regular, and, to our eye, the intermixture of white with the rich, golden-orange is no improvement, but many good judges, we must acknowledge, think otherwise. Black top-knots, again, in the hens, do not harmonize with the general tone of the plumage; for whether the variety be gold or silver, each feather of the tuft should be clearly laced. There were some beautiful examples of this in the Silver chicken class at the last Birmingham meeting.

Much that has been said on the Golden is applicable to

the *Silver Poland* also. From the results of the past year, we should assume that it has been found an easier task to breed first-rate birds of the latter than of the former variety, especially with respect to feather. The comb, however, has here been apt to run coarse; and too many pens have been shown in such condition as could only ensure disqualification.

With the Silver birds the Poland classes usually terminated, but several Societies have now adopted an additional class for "*Polands of any other variety*," to obviate the confused medley of several fowls of undoubted Poland blood in the class "for any other distinct breed." At present, we are certainly inclined to think enough has been done for them, though their claim to this distinction was in every way founded on reason. We say this advisedly, since a specific difference between some of these sub-varieties has been positively asserted. Now, we are perfectly willing to admit, that with regard to Polands, as, indeed, to all other fowls, we have much to learn, for the confusion from which what we do know has been gradually elicited, is sufficient ground to avoid the expression of too dogmatical an opinion on matters when the premises admit of so much uncertainty. But can we assert as a fact, that these white, black, buff, and other varieties hereafter-mentioned, are, indeed, "*distinct permanent varieties*?" Careful selection, for many generations, may have done much to establish a near approach to uniformity of plumage, but as yet, we apprehend, this evidence is far from complete; and "*original distinction*"—by which is implied a separate existence from all such very remote times—will hardly, we suppose, be here asked for. The Bearded-white birds (not to be confounded with the "*Albinos*" from the White-crested black) though carefully secluded from other fowls, have thrown many imperfectly-spangled chickens; and rumours attach the same suspicion (for we have not ourselves had ocular demonstration of the fact in this instance) to the buff and black birds.

The latter, however, are strikingly handsome; and, when in good condition, are a feature in any exhibition. Comparatively few specimens have been shown; but, if we remember rightly, Leeds had an excellent pen.

The *Bearded-white*, again, have many friends, and have proved attractive objects on many occasions. The regularity of their top-knots is seldom surpassed, and they are birds of a stout vigorous habit. The point, however, in which they appear to least advantage is the contrast between their blue legs and dark bills with the white plumage. A light-coloured bird requires, in every case, a light-coloured leg, and fortunately for the white Shanghaes and Dorkings, the family colour of the extremities suits that of the plumage.

Of the Buff or *Yellow Polands with White lacings*, enough is not yet known to speak positively of their merits. In those that have been exhibited, the colours have not been sufficiently clear; and hence a confused effect. We are inclined to believe, that had the yellow been of a somewhat darker shade, the contrast of colour would have been better. But in this, as in all other instances where Polands are concerned, it would be unfair to judge of any variety merely from young specimens—form and feather continuing to improve up to the third, if not, indeed, to the fourth year.

Rumours of the reappearance of the *White black-crested Poland* have been abroad during the last year, and one or two fruitless expeditions on the part of keen fanciers were thereby induced. A pen of white birds, with dusky top-knots and hackle, were the only evidence, at Birmingham, of any efforts towards the restoration of this, seemingly, lost race. But these we allude to gain little hope of better things from the same source—the character of the hackle—even supposing the top-knot had been good in colour, being totally at variance with the object in view—a plumage of uniform white contrasting with a perfectly black crest.

There were, also, at Birmingham, good pens of the *Blue Polands with white-crests*, and some spotted, or rather mottled, birds of the same family, both shown in good condition, and deserving notice for this unusual feather. A pen of *Cuckoo Polands*, also, were there exhibited.

If it cannot be inferred, from what has now been said, that Polands, in their different varieties, have equally profited by the skill of the breeder with some other families of our fowls, we are certain that this has happened from no lack of

attention, nor want of appreciation of either their merits or their beauty. But the reason must be sought for in the difficulty that is so generally complained of in rearing their chickens, and their extremely slow growth, points which the utilitarian character of the present day will not dispense with even in the details of our Poultry-yards. As profitable poultry, we can say little in favour of the Poland; and thus we are not surprised that the anticipations of many of their sanguine admirers in the earlier part of the past year, which led them to expect greater popularity for their favourites than they have since attained to, have proved groundless. If the Shanghae, whose rapid upward course was in a great measure attributable to the idea of its profitable character, has been somewhat dimmed in its hitherto triumphant course, its competitors have been the useful Dorkings and Spanish; and birds of feather only, Polands perhaps more especially, have failed to gain the vacant place, however meritorious in the eyes of those who are attached to birds of this character.

ARABIAN LAUGHING PIGEONS.

WE have now in our possession a pair of these curious birds. The cock bird is pale blue, with very beautiful and a very strong metallic iridescence on the neck feathers. The hen is mottled blue and white, and much smaller than her mate. They are under the average size of Pigeons, and have red unbooted legs. The beak is somewhat more hooked than usual, but otherwise there is nothing in their appearance, to an unpractised eye, distinguishing them from a common Pigeon. Their varied cries, however, are certainly extraordinary. Some of the notes are those of a loud, coarse laugh; but it is, when they are much alarmed, more like a hoarse clamour.

The gentleman from whom we have received the Pigeons writes as follows:—

"Their originals I bought and sent home by ship. They come from Arabia, and cost me two dollars per pair. They vary in colour, being mostly blue, red, and white. I have bred them white, pied-blue, and mottled.

"They stand our climate tolerably well. The different sounds they make are very strange, and when breeding they utter several different kinds of cry. Indeed, any one that had never heard them would be puzzled to know what was the cause of the sounds they make, and I think you and your friends will be very much amused to hear them, as my friends have been. They would not have thought Pigeons capable of making so many different sounds. I feed them with wheat, tares, barley, and a little hempseed, ounce daily. They are fond of different kinds of greens.

"I dare say you will not hear them for a day or so, until they get accustomed to your place. In addition to this, if they are disturbed at night they make those laughing sounds, and should they see a light they immediately commence, being thus almost as good as a house dog. One night I was aroused by them, and knew that some one was in their place, and on getting up found my man had got up much earlier than usual to commence his brewing. This set them all in full cry, and in one respect they are better than a dog, for they are not so easy to quiet.

"Those I have bred in this country stood the climate pretty well, but I find that it is better to keep both them and the English Fancy Pigeons shut in when it is very cold, or very cold and wet with it. I find neither my Pigeons nor poultry stand the damp, cold weather well, especially when the wind is either in the north or east."

CEDAR OF LEBANON,

AT STANFORD COURT.

A CORRESPONDENT in THE COTTAGE GARDENER for January 26, page 328, in speaking of remarkable trees, states that in the county of Kent there are some fine old Yew Trees, and he also states there is (what he thinks) the finest Cedar of Lebanon he has ever seen, but he does not state the dimensions. Now, I would beg to inform "A correspondent" that there is growing in the kitchen-garden, at Stanford Court,

Worcestershire, a Cedar of Lebanon, which I think there are few in England equal to; at least, I have not heard of any; the dimensions of which are as follows:—Height, about seventy-five feet; circumference at two-and-a-half feet from the ground, nineteen feet; diameter of branches, one-hundred-and-twenty-two feet the one way, and about eighty-five feet the other way, and covering a circle of ground measuring three hundred-and-eighteen feet.

Although the size of the trunk may not appear very large, it must be borne in mind that is the smallest part between the root and branches, which are only five feet from the ground. The main feature of this noble tree is the enormous length of the lower branches, which are supported by strong props, the present number being twenty-five. This fine tree was planted in its present situation about the year 1749, rather more than one hundred years since; the soil it grows in is a very deep strong loam; the soil, indeed, seems to supply the necessary food, for the Cedar seems perfectly at home there. This tree would, I have no doubt, have been much handsomer, but the heavy falls of snow that we had some ten or fifteen years since deprived it of several of its largest upper branches.

I should be glad to hear, through the medium of THE COTTAGE GARDENER, where the largest and handsomest Cedar is to be found in England, together with height, width, and breadth of ground it occupies.—C. X.

[We shall be much obliged by descriptions of Trees, distinguished for their size, beauty, or local traditions.—Ed. C. G.]

DISCREPANCY IN JUDGMENTS.

GOLDEN-PENCILLED HAMBURGHES.

WILL you kindly permit me space for a few lines in your paper. I am anxious to know which is the chief point in a Golden-spangled Hamburg cock. I have asked many judges, but they have all been of different opinions; perhaps some of your kind readers will enlighten me on the subject. Last year I bred for ear-lobe and bronze-tail, with great satisfaction. I witnessed the result, and obtained first prizes at the Baker-street, and Surrey summer shows. I exhibited the same birds at a small show soon after, and was beaten for the first prize. The cock in the first pen had certainly a tail of nothing but bronze, though in every other respect was nothing of a bird; he had no white ear-lobe, a comb almost round, with scarcely any point, and had bad carriage, too. With reference to the pullets, there was no comparison. Upon enquiry why these birds had the *first prize*, one of the judges remarked—"Oh! that bronze-tail will take a prize anywhere." But notwithstanding this, my opinion is, that a bird with a good ear-lobe, a good pointed comb, tail nicely edged with gold, and perfect carriage, ought certainly to go before a tail of all bronze, if the birds be deficient in other points. No doubt, many of your friends will benefit, as well as myself, if some of your kind readers give us their opinion upon the matter.—LIVE AND LEARN.

POLMAISE HEATING.

I READ every word of your very valuable Periodical, and I never consider my week's work properly over if I omit the doing it, but absence from home prevented my seeing your number for the 8th of December, in which Mr. Golightly has come down so heavily upon my favourite Polmaise, and my attention was only called to his charge a few days ago. I am afraid Mr. G. will have begun to think that no one doubts what he has said. I am, however, glad to see, by your publication this week, that I shall not be the only champion for Polmaise.

I warm my house by Polmaise, and no one could tell that they were not in the natural heat of summer; in the Pine stoves the air may be kept at any degree of moisture, by the tank for water directed by Mr. Meek to be placed in all Polmaise stoves, and by the application of water on the floors of the chambers under the beds over the walks.

There is no smell, unless, as I admit, some accident has

happened to the flue, but that is readily cured in a few hours. If the houses are properly constructed, you may heat the bed without increasing the temperature of the house, and by admitting air by the flues beneath the bed, which should lead through the outside wall, you can have any amount of fresh air into the house, day and night, slightly warmed.

As to the scorching, singing, roasting, blistering, blotching, and curling, I am quite sure that they are not to be attributed to Polmaise. It is very strange, that houses so frequently suffering, according to Mr. Golightly, from the inroads of sulphur, should be such fruitful nurseries for red spider, thrips, and scale. I had an impression the red spider would infest an open Peach wall, certainly beyond the reach of Polmaise, unless well looked after, and I have formerly had the foliage of Peach-trees entirely destroyed by it. As Mr. Golightly and I reside in the same locality, I should much like to see his unfortunate Polmaised houses, and argue the merits of the system with him on the spot. You may, if you please, exchange my address with him for his own.—T.

PICKLED NASTURTIUM LEAVES.

In a recent article, by Mr. Fish, on the subject of Capers, he observes, that Nasturtiums form an excellent substitute for the favourite adjunct to boiled mutton. He does not, however, mention a fact of which probably many of your readers are unaware, namely, that *Nasturtium leaves* are equally available for the above-mentioned substitution, with the green Nasturtium seeds usually employed.

All that is necessary is to gather the healthy leaves at any period of their duration and to bottle them in vinegar; a proportion of these being chopped up and mixed with the melted butter, when required for use. The plant intended, is the common garden Nasturtium or Indian Cress, the *Tropaeolum majus* of botanists, and not any species of the dissimilar genus *Nasturtium*.—M. C.

GOATS.

MILK is becoming, with other necessary articles of food, dear and of bad quality; and it is desirable that labouring men with families should be aware that, where they have a little outlet, or small inclosed garden, a goat or two may be kept so advantageously as to abolish the "sky blue" and milkman's bills together.

On the continent, and especially in the North of Germany, Goats are kept to a very great extent, and they are of large size, giving a very considerable quantity of milk, which every one who has tasted it knows to be of the best quality.

I was speaking on this subject, this day, to an intelligent native of the Black Forest, and he informs me that there every poor person has a Goat, which browses on the Forest in the summer, and stays at home during the winter, in a shed, giving milk for about eight months in the year. In the summer they are driven out at six o'clock in the morning, fetched in to be milked at eleven; kept in the shed during the heat of the day; driven out again about five; and brought home and milked again about eight. In the winter they are milked only once, and fed principally upon rough hay; but in such localities the country is wild and uncultivated to a great extent, abounding with rocks and plants, to which the animal is very partial: and in such places no material mischief can be done.

This is the difficulty in an enclosed and highly-cultivated country like England, for Goats are so mischievous that they would not be permitted to be at large, and it would be most praiseworthy on your part, if you would, in a set treatise on the subject, in the columns of your publication, point out to your readers a *practical mode* of keeping and using these hardy and valuable animals, beginning with the *enclosure*, or place where they might be kept; their food and manner of treatment generally. They will bear almost any treatment, and have been known to *give milk* and thrive on board a ship, in stormy weather, when fed upon brown paper; and, as I have read in your pages, when fed upon pigtail tobacco, carpenters chips, and kippered salmon; so there is no diffi-

culty where a man has a garden. There is the *prejudice* to be got over, and perhaps that is the greatest obstacle of all; and where *servants* (?) have to milk them, I don't know what would be done; for servants, now-a-days, through learning so much, are above their calling, and can with difficulty be found able to milk cows, or fit (as Cobbett says) to take care of a cat. Indeed, in this neighbourhood, there is so much bother about education, that I verily believe the *real philanthropists* among the promoters of it think that education will alone feed, clothe, and lodge, every human being, without any thing besides. I mean their *book* education; far different from the opposite sort of education I contemplate, namely, the teaching every child to set a just value upon every object it may come in contact with, and to take care of everything they are intrusted with, either belonging to themselves or their employers. On the contrary, they are now taught enough to enable them to read those destructive periodicals which are issued in swarms from every petty shop in almost every street, which make heroes of thieves, and attractive characters of murderers; and the effect may be imagined. I am sorry to trouble you so much; I should not have done so, but from a conviction, that in your hands the subject may be made useful to the great population of the country.—THOMAS STANDBRIDGE, Edgbaston.

[Editors ought to know everything; and we do know some little about Goat-keeping; but we shall be obliged by any one sending us the results of his experience, and mode of treatment.—ED. C. G.]

TO CORRESPONDENTS.

TREES AND SHRUBS FOR A DAMP PLACE (A. S. B.).—They might have been all planted by this time had we known your wants before. The large-leaved Alder (*Alnus cordifolia*), Cut-leaved Alder (*A. laciniata*), Deciduous Cypress, Balsam Poplar, Ontario Poplar, and the so-called Black Italian Poplar, White Willow, Duke of Bedford Willow, Brittle Willow (*Salix fragilis*), and the Goat Willow (*S. caprae*), American Plane Tree, Scarlet Maple (*Acer rubrum*), and White Maple (*A. eriocarpum*), are among the very best ornamental trees for a damp place. The *Spruce Fir* grows beautifully in deep, moist soils, and in low situations, far better than on dry soils. The *Common Holly* and all the variegated ones, will also grow on your filled-up pond; and so will *Filberts*, *Blackthorns*, and *Privet*: also common *Laurels*, to an enormous size; and round the sides, *Weeping Birch* does much better than on dry soil; and the *Deodara* grows with its roots nearly in the river, on the left hand, as you enter Oxford from London, and nothing can do better—the Willows close by do not look better. The following shrubs will do with you, and look very ornamental:—The common evergreen Berbery (*B. aquifolium*), *Magnolia purpurea*, Scarlet Dogwood, Sweet Gale, *Comptonia asplenifolia*, Snowdrop Tree, Scarlet-berried Elder (*Sambucus racemosa*), common Elder, common Honeysuckle, *Calycanthus flurida*, most of the common *Rhododendrons*, *Andromeda florabunda*, *acuminata*, and others; *Pernetia macrantha*, and *Fuchsia*, all which you can get at the Nurseries; and all these names are the common nursery names by which to ask for them.

A MATCH FOR SAPONARIA (*Sarah*).—The white Sweet Alyssum is the only white annual that will match your pretty lace bed of *Saponaria catalbrica*, and flower it out till the frost stops them both. You might have a crop off both beds before you planted out the autumnal crop, say a blue *Nemophila* and *Eucardium grandiflorum*, a bright rosy-pink flower. These two might be sown next week, and they would be in flower by the last week in May, and continue a month; then, by growing the *Alyssum* and *Saponaria* in pots, sown at the end of April, they would be ready to fill the beds the day you parted with the blue and pink. There are no new annuals fit for beds that we have not mentioned in the two last volumes. The little camomile-like *Cenias*, which we spoke of, are hardly yet in the trade.

TROPEOLUM (*Ibid*).—No one can account for the roots of this plant not growing. It often lies twelve months dormant. Keep it a little moist till June, and try it again.

SOUTH-WALL (*Ibid*).—A good winter Pear is the most useful fruit; and a *Wistaria sinensis* the best flower for your wall with the east current of wind in that part of the country. *Passe Colmar*, *Winter Nelis*, or *Beurré Rance*, are among the most suitable winter Pears.

BOUNDARY BELT (*Fillingham*).—Large common Laurels, Privets, Hollies, and Tree Box, are the best to plant under large trees in a belt, through which you want to hide the view, but Portugal Laurels, Yews, Alaternus, &c., would not suffer from the drip of the large trees. Without strict attention to *two rules* it is perfectly impossible to establish a screen of evergreens under old, large, forest trees. The first rule is, that the plants be not less than four feet high; and the second is, that the planting be done in September, or early in October. Spring planting will not do were you to water the plants three times a day through the summer, and for this reason, the more you watered, the more you would encourage young roots from the foresters to rob your evergreens. When you plant in September, cut every root you find in the ground, make the hole rather larger than if there were no big trees, and plant a little deeper than usual, then mulch, and the old and new plantations, or rather their roots, will start on more equal terms next season.

BORDERIS ASIATICA (K.).—This is the name by which you must ask for the *Kushmul Berbery*. It is just the plant to keep people to the path across the field. You will probably have to advertise for it. We have not the slightest idea where it is to be sold, but every nursery in which Thorns, or Quick for hedges are grown, ought to have it on sale.

POLANDS EATING EACH OTHERS' CRESTS (T. K.).—Fowls of several varieties are occasionally addicted to the habit of plucking out, and also eating their companion's feathers. We have noticed it in Shanghaes, where the birds having been kept without a proper supply of animal food, the young feathers immediately after moulting are taken as a substitute, and the practice thus acquired is rarely extinguished. But Polands seem to be specially given to this vexatious trick, particularly in the exhibition pen, as if it were a mere diversion to while away their time. The top-knot, however, being here the favourite point of attack, some disfigurement ensues, for which, when the practice has become habitual, we know of no effectual remedy. In the cases before alluded to, the provision of the proper diet would have, probably, obviated the mischief, but the habit, we believe, is rarely given over.—W.

BUFF SHANGHAES (C. P.).—"Which bird would be the most profitable to breed from, either for sale or exhibition, a pullet, with its exterior feathers of a beautiful buff colour, but the under part of the feathers of a dark or slaty colour; but the other bird equally good externally, and also free from slatiness underneath?" We are of opinion that probabilities are in favour of the latter, grounding our opinion upon the fact that the less dark colouring matter there is in the plumage of the parents, the less is there, usually, in the plumage of their chickens. This increases the value of the latter, there being a taste for pure buff. In our opinion, however, a slight and regular necklace adds greatly to the beauty of a buff bird; and let it never be forgotten, that all good judges of poultry give the palm to beauty of form and high condition, in preference to mere purity of colour. We have known first-rate pure buff birds bred from slaty fluffed buff Shanghaes; and we have known dark birds come from the purest buffs. This arises, probably, from a dark cross in a previous generation of their ancestors.

FLOWER-GARDEN (E. H. C.).—Your geometric flower-garden is on a capital plan, and you cannot go wrong in planting it. Keep the strongest colours, as scarlet, purple, or yellow, in the corner beds, and the rest will do with plain or mixed colours, or with borders as you propose. We never saw these exact figures for corners, but they are exactly to our liking, and we think original.

FLOWER-GARDEN (A Young Gardener).—Your plan is very good indeed, and most easy to plant, and if we did but know the entrance to it, or the side next the window, or that from which it is most seen, we could help you a little, although we do not profess to plant a single bed for anyone. Supposing we enter by the centre walk, between 1 and 2, then the first two beds, 4 and 5, should be with the same plants, in mixed and subdued colours, as Heliotrope, and some grey Verberna, or Mangle's variegated Geranium, or any other variegated Geranium, with or without other mixture; recollect, the two must be exactly alike, and they must neither be scarlet, nor yellow, nor strong purple. 11 and 12 must be alike, and so must 17 and 18, also 24 and 25, and anything you please may be in all these, except scarlet, yellow, and reddish-purple. *Emma* Verberna, and any grey or light Verberna would be very proper for any of these pairs. Then the circles 8 and 21 to be of a different colour from any of the pairs or match-beds along this centre; white, yellow, scarlet, blue, or even green, will do for these two circles, and each of them must be of one colour, but the two need not be of the same colour. 3, 10, 16, and 23 should have scarlet, yellow, and bright purple, with or without borders of an opposite colour; and if you could manage the same colours, but with different plants, for 6, 13, 19, and 26, you would be perfect as far as it is possible for that figure. 14 and 15 depend on the colours in 8 and 21. There ought to be four distinct colours in these four circles—1 and 2 to be the same colour, 7 and 20 ditto, 9 and 22 ditto, and 27 with 23 ditto also. Each of these pairs ought to be of a different colour from that in each of the two large beds next to them; but, as we do not know what those large beds may be, all we can do is to say, plant all the pairs with neutrals, or dark blue, dark purple, or pure white; but recollect, all this depends on entering at between 1 and 2, or between 27 and 23. Your plan will be engraved some day.

POULTRY JUDGES (George Crocker, Plymouth).—It has been wisely determined that Judges at Poultry Exhibitions are not bound to give the reasons for their decisions, excepting only in such cases as an exhibitor, feeling himself aggrieved by the awards, appeals to the committee or managers, who, if there appear just cause, would then refer to the Judges. We cannot doubt but that in any instance of this kind the required information would be immediately afforded, but the application should be made at once. The Rev. G. Hodson was the Judge at the Plymouth Exhibition in January last.—W.

CRAMP IN CHICKENS (Miss C.).—Nothing causes this more commonly than allowing them to be at night or during the day on a brick floor. When under cover nothing is better than a floor covered with dry sand and a very little hay scattered over, and a little green food daily. Removing the chicken attacked into a warm place, and giving it half-a-teaspoonful of brandy is the best remedy.

FIRS (M.).—Those you mention are raised from seed, sown when ripe. They are too cheap to be worth your while to propagate them.

POMOLOGICAL SOCIETY (G. T. S.).—Write to Mr. Hogg, 13, Gilston Road, Brompton.

LUCERNE (J. S.).—Where this has failed you had better mix a little super-phosphate of lime with the soil, and sow afresh early in April.

RANDES' PRICE CURRENTS (F. H.).—You can obtain both the Horticultural and Agricultural Price Currents by remitting twelve postage stamps to Messrs. Randle, Nurserymen, Plymouth. We quite agree with you in thinking they contain a large amount of information. Embracing as they do cultural directions, an almanack, and advertisements, they differ essentially from a common catalogue of plants.

GAPES (Fuller).—When Mr. Tegetmeier directs for the cure of this disease that the fowl be made to inhale the fumes of spirit of turpentine

"as long as it can withstand its influence," he means until it gasps for breath, which you can perceive by raising the lid of the box in which it is being exposed to the fumes.

VARIOUS (Ibid.).—You must write to Capt. Hornby for prices. The most economical feeder is a trough placed behind a palisade, so that the fowls can reach it with their beaks but not with their feet. We have no experience of *wicker nests*. It is quite immaterial what wood false nest eggs are made of, because they must be painted white.

STURGEON'S SHANGHAES (Helen).—We believe Mr. Sturgeon was dissatisfied at some decisions where he exhibited, and, as he had abundance of laurels, he could afford to withhold from exhibiting. We hope he will determine otherwise this year, for his birds, as a whole, have never been surpassed.

BECK'S GEM (A Subscriber, Tavistock).—You will have seen what a correspondent said last week as to the restricted supply of this Pea.

ARTIFICIAL MANURE FOR POTATOES (Cantab).—You ask "which is the best for them?" Yet you do not say a word as to the nature of the soil. You might as well ask a physician what is the best medicine for you, without giving him the slightest further information. We never manure for Potatoes, but grow them on plots rendered sufficiently fertile by the manuring for previous crops. If we were obliged to manure for Potatoes, we should select a light, poorish soil, and apply at the rate of forty bushels of soot, twenty bushels of common salt, and two cwt. of Epson salt per acre.

PLAN OF MELON AND CUCUMBER HOUSES (John Carne).—"The use of this, in No. 259, is frustrated," you say, "as we are left totally in the dark as to the expense of such a building." We have given, several times, the general price of articles—beyond this we do not feel it to be our province to go. Several times we have calculated, for ourselves and others, what such and such buildings should cost, and have been frequently put out by the structure costing more or less than we bargained for; these being greatly influenced by the locality, and changes introduced by the owners. Tradesmen would do better to state what such and such sized houses could be put up for. Meanwhile, if the obliging subscriber who sent the plan, No. 2, 259, would also send an account of the expense the house as it stands cost, he will confer a great favour on many readers.

MUSCAT AND BARBAROSSA GRAPE FOR A LATE HOUSE (E. M.).—You are quite right—the *Muscata* will require more heat than the *Barbarossa*, but still we would plant one house of equal parts of both, in preference to one alone. We have set *Muscats* very well, though on the next rafter were *Hamburgs*. You may keep the *Muscats* at the warmest end, and just give a little less air there when the fruit is setting.

ORANGE TREE (W. M. S.).—We are rather doubtful whether you have raised it from seed or from a cutting, as these are called pipings by some florists. If the former, you will not easily fruit it in a window, and had better have it inarched or grafted with the Otahite, the Lemon, or any free-flowering variety. If you wish to try it as it is, give it all the light you can, sponge its leaves frequently, water with manure-water, or give a rich top-dressing, inure to air, and by the middle or the beginning of June set it out-of-doors, in a warm place, against a fence; give it plenty of water there, and house again by the beginning of October; and very likely, next spring, you will get blossoms, to be followed by fruit. The first will be delightful, the second of little use.

GLAUBER SALT FOR POTATOES (A Reader).—The ashes of the tubers of Potatoes contain about 56 per cent. of Soda and Potash, combined with Sulphuric and other acids. We know of no experiments upon Potatoes with Glauber Salt (Sulphate of Soda). If you employ it, sow it by the sides of the rows when the Potatoes are well up in the spring. Do not use more than 2 lbs. for every thirty square yards.

SCALE ON APPLE AND PEAR TREES (A. B. W.).—Yours is the Musclet Scale. Try applying spirit of turpentine by means of a hard brush.

CANCER (E.).—It is quite impossible we can publish the information you require, but if you will enclose your address in a stamped envelope directed to "The Authoress of My Flowers," it shall be forwarded to her unopened.

CANARIES' NESTS (E. G.).—Wool, dry moss, and horse-hair are best for them. We knew Canaries loose in a room that built their nest on a cornice from the thread, &c., in a lady's work-box.

BRAHMA POOTRA COCK (H. S.).—We cannot give you any "marks" whereby you may distinguish him from "Cochins or Shanghaes," because we are more and more convinced that the so-called Brahma Pootras are nothing more nor less than "Cochins or Shanghaes," with white plumage, and sprinkled more or less with black feathers. The good points of the Shanghae are also the good points of the Brahma Pootra. *Chickens* should have very slightly moistened Indian and barley meal, mixed with chopped egg, for the first three or four weeks. After that they may have varied food like the full-grown fowls.

WORK ON FARMING (A. W. W.).—Morton's Cyclopaedia of Agriculture will best suit you.

GAS TAR, OR ASPHALT (S. H.).—Flooring, or paths, made of this are not injurious to fowls.

INTENTIONS (A Cottager).—All your purposes are most excellent, and ought to succeed, but we do not see how we can advise you. We are ready to answer any specific question.

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kaladar; and Published by WILLIAM SOMERVILLE ORR, of Church Hill, Walthamstow, in the County of Essex, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—March 2nd, 1854.

RENDEL'S PRICE CURRENT.

Opinion of George W. Johnson, Esq., the Editor of the "Cottage Gardener":—

"Your Price Current, so well got up, is excellent, and full of useful information."

RENDEL'S PRICE CURRENT.

Opinion of Mr. George Glenn, the Editor of many of the leading Horticultural publications of the day:—

"THE TRADE CATALOGUE.—No documents are more interesting to the gardener than the catalogues of the trade, when such documents are original. They have ceased to be plain lists like each other, and already assume more important forms.

"RENDEL'S Price Current is a complete work, containing, independently of the lists and prices of everything, a history of the leading subjects, with directions for Culture, a general Calendar of Operations for the year, and a mass of information appertaining to the garden. The Seed Catalogue is on a plan of selection, giving assortments at various prices for large and small establishments, and there are many pages of Advertisements. It is a great improvement on the one last year."

RENDEL'S PRICE CURRENT.

Opinion of Mr. Jennings, Head Gardener to Earl of Derby, Knowsley Hall, Prescot:—

"Your arrangement of the Calendar reflects great credit on you, and must have proved a heavy task. The remarks about rotations, preparers, &c., will lead to much good. You really deserve the best wishes of all gardeners for the task you have performed in so masterly a manner."

RENDEL'S PRICE CURRENT.

Opinion of Mr. D. Benton, Surbiton, Kingston, Surrey, one of the most popular Horticultural writers of the day:—

"I have a copy of Mr. RENDEL'S Price Current for this year, and I can tell you at once that it is the most useful Catalogue and Calendar that was ever sent out from any house of business in our line, and I do not see what more you could add to it by way of usefulness. How different from the bare-bone lists to which you and I had access when we first took to the spade on our own account!"

RENDEL'S PRICE CURRENT has been already favourably noticed by the following Newspapers and Magazines:—

"Mark-Lane Express," "The Lady's Newspaper and Pictorial Times," "The Florist, Fruitist, and Garden Miscellany," "The Gardener's and Farmer's Journal," "The Agricultural Magazine," "The Plough," "Lloyd's Weekly Newspaper," "Plymouth Herald," "Exeter Gazette," "Bristol Mercury," "Western Luminary," "Somerset County Herald," "The Clerical Journal," "Cornish Telegraph," "Plymouth Mail," "Devonport Telegraph," "Somerset Gazette," "Western Courier," "Teignmouth Gazette," "West Briton," "Portsmouth Times," "Naval Gazette," "Southern Florist," "Midland Florist," "Stockport Advertiser," "Liverpool Advertiser," and several other Newspapers and Magazines.

RENDEL'S PRICE CURRENT.

Opinion of Mr. Hamilton, the well-known Author of the "Hamiltonian System of Pine Culture," &c.:—

"Your descriptive remarks in RENDEL'S Price Current, together with the mode of handling the subject, eclipses everything of the kind ever published to the gardening world in that form. It will be invaluable to the young gardener and the amateur, and every practical gardener should have it as a reference. My opinion is that it will be exceedingly useful to seedsmen, and I believe that when it is known, almost every seedsmen in the kingdom will purchase it."

RENDEL'S PRICE CURRENT.

Opinion of the Editor of the "Florist" for February, 1854:—

"RENDEL'S Price Current and Garden Directory for 1854 contains elaborate descriptive lists of vegetable and flower seeds, in addition to much other useful matter, not the least of which is a Calendar of Operations by Mr. Errington. We can only hope the information Mr. RENDEL puts before his customers may meet with a hearty response."

THE ROSE GARDEN,

By WILLIAM PAUL, of the Nurseries, Cheshunt, Herts.
"Infinitely the best work ever written on the Culture of the Rose."—*Botanic Garden.*

By the same Author, price 1s,

AN HOUR WITH THE HOLLYHOCK.

London: PIPER BROTHERS & Co., 23, PATERNOSTER ROW; and all Booksellers.
New Edition, Price 8d; or by Post, of the Author, Kelsale, Saxmundham, Suffolk, 1s.

READ'S GARDEN ENGINES, SYRINGES,

ETC.—When an article of real utility attracts public attention, IMITATORS start into the field to snatch from the inventor the just reward of his labours. It has now become a daily practice to exhibit in the windows of ironmongers and others, Syringes of the very commonest description, with the words

"READ'S PATENT,"

as an inducement to purchasers. This, as an eminent writer on Horticulture has recently remarked on the subject, is indeed "living upon another man's fame."

READ'S Instruments have the Royal Arms, with the address, 35, REGENT-CIRCUS, LONDON. Description sent post free.

RENDEL'S PRICE CURRENT.

Opinion of Mr. W. Tillery, Gardener to His Grace the Duke of Portland, Welbeck:—

"My dear Sir.—I beg to return many thanks for the copy of Rendle's Price Current and Garden Directory for 1854. As far as my experience goes, I think your Calendar of Operations excellently planned, and the Directions are judicious and quite up to the mark for the present progressive period. The remarks on the systematic rotation of vegetable-cropping are likewise excellent, and will do much good if carefully put into force.—Yours truly,

"W. TILLERY."

RENDEL'S PRICE CURRENT.

Opinion of the Editor of the "Ladies' Newspaper and Pictorial Times":—

"RENDEL'S PRICE CURRENT FOR 1854.—This is one of those publications which, from their practical utility, are sure to recommend themselves among the large class to which they appeal. Their usefulness is their great recommendation, and no one connected with gardening or horticultural operations can do without such works. The proprietors of RENDEL'S Price Current have received so much encouragement from the great success of their publication in former years, that it has stimulated them to make the present in every way worthy of the distinguished patronage enjoyed, as well as to support the high position they have gained in connection with it. MESSRS. RENDEL not only give a complete catalogue of prices of the various seeds, but much useful and practical information connected with gardening. Generally, and in practice also, we may refer to the operations of the month; the present one (January) we extract in another portion of our paper, as a sample of the useful matter contained in the work, which is heartily recommended to all our fair readers who take a pleasure in the pursuits of gardening."

RENDEL'S PRICE CURRENT.

Opinion of the Editor of the "Midland Florist and Suburban Horticulturist":—

"We had last year to praise the very excellent Descriptive Catalogue of Seeds issued by MESSRS. W. E. RENDEL & Co., of Plymouth. We have had the one for the present year just sent us. It certainly is the best of the kind which has ever come under our notice, and to proprietors of gardens, whether large or small, must prove eminently useful. Under the head of each Vegetable are enumerated the best varieties, with its native country, proper mode of cultivation, &c., combining the most improved systems up to the present time; added to which are Lists of Flower Seeds, proper modes and hints on sowing, with a very complete Calendar of Operations by Mr. Robert Errington, gardener to Sir P. Egerton, a sufficient guarantee of its excellence."

RENDEL'S PRICE CURRENT.

Opinion of Mr. James Barnes, the well-known Gardener to the Right Honourable Lady Rolle, Bickon:—

"Dear Sir.—Your Price Current has just come safe to hand, and I beg to return my best thanks for the same. It contains a great deal of useful information for all classes, more particularly for the Amateur and those who cultivate their own Gardens and Allotments.—Yours, &c.

"JAMES BARNES."

RENDEL'S PRICE CURRENT.

Opinion of the Editor of the "Southern Florist," Feb., 1854.

"This work or pamphlet, as the title indicates, constitutes a Descriptive Catalogue of Vegetable and Flower Seeds offered by the firm of RENDEL & Co., of Plymouth; but while it contains all the useful matter found in a Catalogue, copious descriptions of the newest and most approved Seeds are given, together with a mass of sound and useful information, which cannot but be valuable to the Amateur as well as the practical Gardener. It contains an Almanack for the year, a copious Calendar of Operations for each month, directions for Rotation, Cropping, &c. &c., and is stamped to go post free to any part of the United Kingdom—forming a complete newspaper of over 50 pages of useful matter."

RENDEL'S PRICE CURRENT.

Opinion of the Editor of the "Mark Lane Express":—

"An annual publication or Trade Catalogue of Horticultural Seeds, with lists and prices of sorted collections proper for large, moderate-sized, and small gardens; containing also various excellent hints and practical observations on the best modes to be pursued in the proper cultivation of general garden productions."

SUTTON'S FINE LAWN GRASS SEEDS, FOR

improving Old, or making New Lawns. Price, 1s 3d per pound, 3s per gallon, or 21s per bushel. Two-and-a-half bushels (or forty pounds) is the quantity required per acre, for forming a new Lawn.

The following is an extract of a letter received from Dr. Lindley, the greatest Horticultural authority of the present day:—

Messrs. Sutton.—We have already made trial of your Lawn Grass Seeds, and it is but justice to say they have proved the best we have sown for many years. (Signed) JOHN LINDLEY.

Horticultural Society, Regent Street, London, Nov. 9, 1853.

We are almost daily receiving similar letters to the above, and have great confidence in stating that the sorts of Grass Seed we sell in our "Fine Lawn Mixture" are the finest and purest in cultivation.

Quantities of 20s value and upwards are sent carriage free.

JOHN SUTTON and SONS, Seed Growers, Reading, Berks.

WILLIAM NICHOLSON still continues to send

out very strong well-rooted Plants of his four new and distinct varieties of STRAWBERRIES, viz., AJAX, Desert Fruit; RUBY, ditto; CAPTAIN COOK, Market Fruit; FILL-BASKET, ditto, at 15s per Hundred, or Twenty-five each of any two sorts for 10s, box included.

Post-office orders payable at Yarm, Yorkshire. For a full description, see Advertisement, *Gardeners' Chronicle*, Jan. 28, 1854.

Eggescliffe, near Yarm, Yorkshire.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 50.6° and 33.6° respectively. The greatest heat, 69°, occurred on the 9th in 1826; and the lowest cold, 7°, on the 10th in 1847. During the period 114 days were fine, and on 75 rain fell.

BRITISH WILD FLOWERS.

(Continued from page 353.)

CARDAMINE.—LADY'S SMOCK.

GENERIC CHARACTER.—*Calyx* a little unequal at the base; leaves oblong-egg-shaped, blunt, slightly spreading, de-

ciduous, two of them protuberant, in some degree, below their insertion. *Petals* reversed-egg-shaped, rather upright, undivided, tapering at the base into short claws. *Filaments* awl-shaped, simple, the two shortest with a gland at the base, next the calyx. *Anthers* small, oblong-heart-shaped, acute, curved back. *Germen* line-like, slender. *Style* scarcely any. *Stigma* blunt, entire. *Pod* stalkless, erect, line-like, compressed laterally; valves flat, without ribs, scarcely narrower than the bordered partition, bursting elastically from the base, and mostly curling back. *Seeds* egg-shaped, not bordered, inserted alternately in a single row; their stalks simple, short and slender; cotyledons accumbent.

CARDAMINE BELLIDIFOLIA: Daisy-leaved Lady's Smock; Daisy-leaved Cress; Alpine Cress.

Description.—It is a perennial. *Root* rather woody, divided at the crown. *Herb* two or three inches high, unbranched, erect, bright green, smooth. *Leaves* simple, egg-shaped dark green, entire; the root ones much shorter than their footstalks, sometimes a little wavy or angular, the uppermost nearly stalkless. *Flowers* few, flat-bunched, terminal. *Calyx* purplish. *Petals* white, erect. *Style* short and conical. *Pods* hardly an inch long, crowned with the round-headed stigma, on a short thick style, strap-shaped, blunt, and smooth.

Time of flowering.—August.

Places where found.—Many errors have occurred about this plant, *Tarritis hirsuta* being mistaken for it, but Mr. Milne found species of it wild in Scotland, and Dr. Withering, jun., says—"Of these being genuine there can be no doubt." As it is found in Lapland, and near the summits of the highest Alps, it should be sought for far north in the British islands.

History.—The first mention of it as a British plant is by Ray (*Hist. Plant.* i. 817), who, writing in 1686, says—"It has been lately found on St. Vincent's Rocks, near Bristol, by Mr. James Newton." That botanist, however, must have taken some other plant for it, as it has never been seen there since. By the old writers on plants, it was variously called a *Nasturtium*, a *Sinapis*, and a *Cardamine*, but almost always with a specific name, referring to its Daisy-like leaves.—(*Smith. Withering. Martyn. Ray.*)

The greatest surgeon who ever lived was accustomed to declare that he never approached the operation table without a feeling of humiliation, for he was convinced that the real triumph of his art lay not at all in performing operations, but in preventing the necessity for them altogether. Hunter's ablest follower, Abernethy, founded himself, as one may say, on this single axiom; and it was a perpetual theme of discourse with Macartney, another of the sens of the giant. We have recently met with the following highly suggestive remarks by Dr. Latham:—

"Prior to diseases; to their diagnosis; their history, and their treatment; prior to them, and beyond them, there lies a large field for medical observation. It is not enough to begin with their beginning. There are

things earlier than their beginning which deserve to be known. *The habits, the necessities, the misfortunes, the vices of men in society*, contain materials for the inquiry, and for the statistical systematising study of physicians, fuller, far fuller, of promise for the good of mankind than pathology itself."

The general aim, then, of this series of papers is not so very much out of the way—not so very unpractical as might at first appear. It must be remembered that all attempts whatever at writing popular medicine have failed. It remains to be of the public to cease to try to do that which the proverb "heal thyself," hints that the physician can hardly accomplish in his own case. But a philosophical and religious inquiry into the remoter causes of disease offers promise of more general

usefulness; and in the way of prevention, and deprecating the judicial punishment of many sins of omission and commission against the natural laws of Providence, every man has it most in his power (under Providence) to become his own physician.

Now the following popular directions for the management of sudden cases of incipient cholera, or choleraic diarrhoea, are, beyond comparison, the plainest of any yet put forward for general use, by authority. Yet to us every sentence breathes a protest against the necessity which required the promulgation of any such document at all. In truth, the true science of medicine is exhausted when once the cholera has been allowed to establish itself. Timely warnings have been unheeded; disastrous courses have been recklessly continued; and when the crash comes, as surely it will come, the business is just like that of winding up a bankrupt estate, and deprecating the just wrath of the creditor and the judge. The same is the case, to a less extent, no doubt, in the incipient stage. It has been found that timely removal to a higher, drier, purer air, aided by good plain food and clothing, is the only effective way to stop an epidemic of diarrhoea, and to prevent its becoming cholera. It may be kept down by incessant attention and physicking, and daily visiting from house to house among the poor, debauched, ill-fed inhabitants of low, damp, dirty, crowded places. So, with all hands to the pump, a leaky vessel may be brought into port with ever so many feet of water in the hold; but is it not far better, when there is a chance, to lighten the cargo and put the passengers on a sound bottom? J. J.

"DIRECTIONS OF THE IRISH COLLEGE OF PHYSICIANS FOR THE TREATMENT OF CHOLERAIC DIARRHŒA AND COMMENCING CHOLERA.

"As the malignant cholera is, in the majority of cases, quite amenable to treatment in its earliest period, or that of premonitory diarrhoea; and, as this being free from pain is apt to be disregarded, all cases of this kind should be diligently sought for and promptly treated. A judicious system of house-to-house visitation should be organised in the poorer districts in every large town threatened with the epidemic. The medical visitors entrusted with the care of the poor should carry with them appropriate remedies to be administered at once on discovering any case of premonitory diarrhoea.

"In addition to this system—by which the committee hope to check the spread of the disease at its first approach—it will be necessary to provide means of relief should cholera become epidemic. In that case, the city should be divided into a number of districts, at some convenient point of which a medical dépôt for each should be established, with a sufficient number of medical attendants to have one always on the spot, both by day and night, to administer medical relief, on application, without any recommendatory ticket, or other formality. Notices should be posted, urging all parties affected with diarrhoea to apply at once for relief; and each district, in the first instance, should be subjected to careful house-to-house visitation. In cases of destitution, there should also be given relief in the shape of nutritious food, as well-boiled rice and milk. The most destitute should be removed to hospitals.

"The services of physicians who have had experience of cholera should be obtained, and a staff of senior medical students organised to assist. Means of conveying patients safely to the hospital should be provided, available on the shortest notice. The patient should be conveyed in the recumbent posture, and vehicles on springs, with beds, and sides padded, with proper means of warming and ventilating, will be required.

"It cannot be too strongly impressed upon the public, that in the great majority of cases of cholera there are two distinct stages, and that precautions should be taken to deal with each of them as it presents itself. The diarrhoeal stage is, in most instances, manageable if treated properly.

"The moment an individual is affected with diarrhoea, when cholera is prevalent, let him get into bed, and take every precaution to maintain the temperature of the surface of his body and extremities by the application of warm blankets or other covering; bottles of hot water, or heated bricks, to his feet and hands; warm flannel swathes to the abdomen; and take a small quantity of whatever domestic stimulant may be at hand, such as punch, made with brandy or whiskey, warm negus, or mulled port wine; and let him send at once for medical aid. As a large proportion of cases occur at night, to avoid delay, we should advise all families to be provided with medicine to meet the diarrhoeal stage of the disease; and as such a medicine should be one which will not injure by keeping it should be prepared and kept in a dry form. The committee advise the following, to be kept in every house, to check looseness of the bowels in slight cases:—

"No. 1 Recipe.—Pulveris cretæ opiatæ, drachm. ij.; Divide in chartulas duodecim.

"Sigma. No. 1.—Twelve astringent powders. One of the powders mixed with a little milk to be taken by an adult (full grown man or woman), after every liquid evacuation, until the arrival of medical assistance.

"If the purging be sudden and violent, let one of the following pills be taken every half-hour instead of the powders:—

"No. 2 Recipe.—Acetatis plumbi, gr. xxiv.; Opii, gr. iii.; Ft. massa et divide in pilulas duodecim.

"Sigma. No. 2.—Twelve astringent pills. One to be taken every half-hour. In cases of sudden prostration, or sinking, a dessert spoonful of whiskey, or brandy, and a table spoonful of water, may be taken every fifteen minutes until the arrival of the physician. In cases of sickness of stomach, let a large mustard poultice be applied over the pit of the stomach until it produces decided irritation. Rice milk or beef tea, with or without well-boiled rice, may be taken in small quantity in the diarrhoeal stage.

"It is not an uncommon, and occasionally fatal, error for persons attacked with premonitory diarrhoea to take castor oil, or saline, and other aperients: this must be strictly avoided.

"When diarrhoea occurs in young people, the dose of the astringent powder, No. 1, must be gradually diminished, reducing the quantity one-half for a child ten years of age.

"For diarrhoea in children under ten years of age, the committee recommend for a child a year old the following powder after every liquid evacuation, taking care not to repeat the dose oftener than every hour.

"No. 3 Recipe.—Pulveris cretæ compositæ, gr. ij. Pulveris cretæ opiatæ, gr. i.

"Misca et Sigma. No. 3.—Astringent powders for children. Two of these powders may be given combined to a child from one to three years old; three to a child from three to five years of age. In a child from five to ten, this quantity might, in urgent cases, be repeated every half-hour until medical assistance is obtained. These should be given in a little milk. Where there is urgent thirst, pure milk, milk-and-water, or rice milk-and-water, may be freely given to drink. If cold water appears to produce chill, a small proportion of brandy may be mixed with it.

"Although desirous to supply information which may be readily available by unprofessional persons, the committee do not deem it expedient to embarrass the public mind with detailed directions for treatment when the disease is developed, or in the secondary state; being fully convinced that in these stages prompt and experienced medical assistance is alone to be depended on as offering any chance of recovery. They shall, therefore, only at present observe, that, in some cases, the disease commences suddenly, with symptoms of great intensity, such as shiverings, coldness of the surface, great prostration of strength, cramps, with purging or vomiting, or both. In such circumstances, while medical aid is sought for, let the patient be immediately put to bed, in a well heated apartment; heat applied to the extremities by bottles of hot-water, heated bricks, &c., while a large

mustard-poultice, or a piece of warm flannel moistened with oil of turpentine, is applied over the abdomen. At the same time the limbs, both upper and lower, should be diligently rubbed, under the bedclothes, with the naked hand or with flannel. In the meantime, any convenient stimulant, such as punch made with brandy, whiskey, or gin, in moderate quantities, or mulled port wine may be taken. The following mixture is recommended as a cordial, that may be used under the circumstances.

"No. 4 Recipe.—Tincturæ Cardamom. composiæ, f. 2 ounces; Spiritus Ammonię aromaticę, f. 2 drachms; Syrupi Zingiberis, f. 1 ounce; miscæ.

"Signa. No. 4.—Stimulant mixture. Two teaspoonfuls, mixed with five teaspoonfuls of water, to be taken every half-hour. The patient should not sit or stand up.

"The committee do not intend to dictate a specific line of treatment for the fully developed disease; yet, as these directions may fall into the hands of persons in remote parts of the country, who may, while the medical attendant is coming from a distance, be obliged, by the attack assuming the alarming character just described, to adopt more energetic treatment;—the committee recommend, in addition to the measures directed in the preceding paragraph, that one of the following stimulant pills be given every half-hour:—

"No. 5 Recipe.—Camphorę, gr. xii.; Spiritus vini rectificati min, iv. In probe conterendo nixtis, adde, Calomelanos, gr. xij.; Opii, gr. ij.; Capsici, gr. iij.; Confectionis aromaticę, gr. v.; Mucilaginis gumani acacię, q. s. Fiat massa et divide in pilulas duodecim,

"Signa. No. 5.—Stimulant pills. One pill to be taken every half-hour."

CONTINUING OUR notes upon the varieties of the garden Pea, we come next to the

PARADISE PEA.

This is a novelty of last year's introduction, which fully maintains the high character with which it was brought out. It is, as yet, very little known, having appeared at a time when the public were somewhat awakened to the necessity of caution with which new varieties ought to be received. As regards this, however, there need not be the slightest misgiving, as I have found it to be one of those which must ultimately become one of the standard sorts if preserved in its present true character. As will be seen from the accompanying figure, the pod is of very large size, remarkably well filled with a deliciously-flavoured Marrow Pea, and is fit to be gathered as soon, or at most within a day of the *Ringwood Marrow*. With such properties, therefore, every one will allow it is a variety well worthy of general cultivation.

The plant is of a strong and vigorous habit of growth, with a stem from five to six feet high, which is branching towards the top. The pods are generally single, but frequently in pairs, about four inches long, nearly three-quarters-of-an-inch wide, remarkably well and closely filled with from seven to nine large Peas, and when they begin to

ripen, they are thick-backed, succulent, and fleshy. The ripe seed is white, round, and smooth.

It was sown on the 5th of April, and came into bloom on the 15th of June; on the 20th the blooms fell and the slats appeared, and on the 11th of July the pods were quite filled and fit to be gathered. From this it will be seen that it does its work very quickly, at least much more so than some others, for although it came into bloom five days later than the *Ringwood*, it was not, even at the utmost, more than two days behind it in podding. It is far superior to *Shilling's Grotto*, being longer in the pod, better and more equally filled, and comes in much earlier. The *Paradise Pea* was introduced by Messrs. Steward and Mein, of Kelso, N. B.

(To be continued.)

R. H.

A LESS suitable period for a Poultry Show than the middle of *April* could hardly be suggested, since a large majority of hens will be at that time occupied either with their young chickens or in the work of incubation. Even with respect to the non-sitting breeds, eggs are then so valuable for hatching that the owners of good specimens of this class will surely be loath then to send them on their travels. With much surprise, therefore, we learn the determination of the *Newcastle, Northumberland, and Durham Society*, to hold their next exhibition on the 19th and 20th of that month. But it is not merely with regard to the time proposed for this meeting that we must express our dissent, for the prize-list, also, is so arranged that little encouragement is there held forth for the exhibition of some of the most valuable of our fowls.

A summary of the amount of premiums to be awarded to the different breeds will best explain our meaning.

	£	s.	d.
Shanghaes or Cochinchinas	10	2	6
Hamburgs	9	15	0
Polish	7	2	6
Dorkings	4	17	6 !!!
Bantams	3	15	0
Spanish	3	7	6 !!!
Game Fowls	2	5	0
Malay	1	10	0

Any Society offering its prizes for the avowed purpose of improving of domestic poultry will justly be required to regard their economical value as one of the most important properties, and, therefore, such fowls as rather come under the head of "*birds of feather*," must necessarily occupy a place of secondary importance. We cannot, then, see the propriety of devoting £16 17s. 6d. to Hamburgs and Polish, while Spanish and Dorkings have between them only £8 5s.; Spanish, moreover, are even placed below Bantams, to which £3 15s. is allotted, the amount for Spanish being £3 7s. 6d.

Every distinct variety of the different families should, if possible, have a separate position on the prize list, but the aggregate amount of each family should bear a proper relation to their acknowledged value. This

principle, we think, is incumbent on any Society that proposes as its object the general improvement of our poultry-yards, although, where Bantams, Polish, and Hamburgs are specially acknowledged as the main objects of attention and regard, no one would have a right to complain of such a distribution as we have now alluded to.

Besides the class for "*any other distinct breed named,*" we find one (No. 38), for "*the best and second best cock and four hens of any of the above breeds,*" involving the difficult, and, under every condition, the unsatisfactory, task of the judges being called upon to decide between fowls of totally distinct form, feather, and properties; and this in addition to the unprecedented number of hens required at a season the most unlikely to have them in readiness for their appearance.

But *Geese*, as they stand on this prize list, claim a word at our hands, since £1 2s. 6d. is all that the Newcastle Society is disposed to offer for the encouragement of this most useful and valuable bird, while Ducks have £5 5s. between them.

Ganders only, we observe, are invited, and this, doubtless, on account of the duties in which their spouses will be then engaged; but by parity of reasoning, we might expect to find cocks, drakes, and male Turkeys, as the only representatives of their different races.

Class 47 is for "*extra stock,*" but it is not stated whether fowls are here admissible, or whether Pheasants and other birds are thus designated. The former, we think, should always be limited to their regular classes, especially where a provision is made by "*any other*" class for their proper representation.

The Cottager "who exhibits the best lot in any of the above classes," has three prizes for his encouragement, but "*no entrance is required for this class!*" The meaning, probably, is, that no entrance fee is to be paid; but surely, it would be difficult to refuse admission on the morning of the show to any such persons bringing their baskets without any previous notice or entry, for the rule would fairly bear that interpretation, and how would the Secretaries be prepared with accommodation for an indefinite number of pens?

In *Pigeons* we have a most arbitrary selection. Runts, in their different varieties, a most valuable bird even for domestic purposes, while their estimation, in some instances, stands so high with the most critical fanciers, are unnoticed. The Bearded, Bald-pate, and self-coloured Tumblers the same. And although Nuns, Turbits, Pouters, Jacobins, and other fancy birds, are admitted, Owls and Archangels are summarily banished. The class for "*any other variety of Pigeons,*" lately productive of many beautiful specimens, is not in this list to be found.

How are the best eggs to be determined on? Is size alone to carry the day, or are the judges to test their quality at breakfast? at which time the merits of a "*butter,*" (of which the connexion with the objects of a "*Poultry*" Society is not quite apparent) will also, we presume, be submitted to their judgment.

These remarks, we need hardly observe, have no

origin in any desire to depreciate the efforts, or prejudice the success of the Society in question; but at this early season of the year, when numerous other prize-lists are in course of preparation, it is but just to our readers to call their attention to any such arrangements as may appear inconsistent with the judicious management of such Associations.

CAMELLIAS.

I AM not about to attempt a monograph of the *Camellia*, our space will not admit of it; although I must confess I have never seen the *Camellia* done justice to as yet in "gude black print", as the Scotch poet said. I wish merely to impress on the minds of cultivators a few important facts or features in its culture; and I am encouraged to do so, from having (people say) the finest bloom of these noble winter flowers that can be imagined at an early period; for my house has been in full blossom constantly since the beginning of December, and will continue so until the early part of April. A lady of distinction, who was here the other day, paid us a rich compliment about them. She said, "Mr. E., your *Camellias* are beyond beautiful!" and I do think she was right, for they are noble as well. I have paid much attention to their culture for many years, with a desire to ascertain how far appliances could be carried, in order to obtain the greatest profusion of flowers of the largest size with the thickest and darkest foliage; and I believe I can now scarcely push the effort any further.

These *Camellias* are all in pots, and are shifted, or repotted, about once in two or three years. On the repotting, which I never allow any one to do for me, I lay the utmost stress. I use, perhaps, more liquid-manure than most other cultivators, and I have long discovered that the man who thus practices must use composts and modes of potting *specially adapted* to that practice. Here lies one of the chief points in the general and systematic use of liquid-manures. My mode of draining the pots would, by many, be thought pushed to an unreasonable extreme; I do not find it so, but the reverse. About one-fourth of the depth of the pot, of whatever size, is occupied with drainage materials; but, be it observed, not entirely of non-absorbent or imperishable materials: one-half of these is turf.

As on the mode of preparing this turf in part depends the beneficial efforts sought to be produced, I may here state my practice. I procure what is termed strong or sound loam, as gardeners call it; that is to say, a loam slightly adhesive, such as gardeners love for fruit-trees—Melons, Pine Apples, &c. This, from an old pasture, which has lain for many years untouched by the plough, and on which there is a sward or turf, as thick and as closely woven as the best blanket, is the material, as far as loam is concerned, and the turfy portion for this drainage affair is pared about two inches thick, the rough grass, &c., being first mowed-off. This, then, is cut into small lumps of various sizes, from that of a walnut to that of a potato, and then charred, or rather steamed, by putting out the fire from a furnace, and introducing the lumps on an iron plate; at the same time stopping up the fire-hole and ash-pit-doors, and throwing an old wet sack or mat on the chimney-top. This is concentration with a vengeance. If matters have been well carried out one cooking may do; if not, why, I give it a second ordeal; sometimes nursing some slumbering embers in the ash-hole to keep the game going. These lumps, when withdrawn, are almost singed, and possess such a pyroigneous scent as to be annoying to delicate nasal organs. In this state

they become very mellow, especially if they were as they should be—tolerably dry when introduced; and here they are well shook and squeezed in a riddle, or sieve, until at least half of the mere soil tumbles out. After this, they are, what I consider, a precious article, and applicable in other cases besides Camellias; but of this, more another day.

Now, before proceeding further, let me fairly assure the gardening world that I by no means suppose that this is the only good practice in Camellia culture. I utterly disclaim all such conceit; not out of fear of angry critics (who must live, as well as other folk), but because I neither can, would, nor ought to attempt, to repudiate the practice of other men of experience. There is, indeed, no monopoly in gardening knowledge. My object is simply to show forth my own practice. I well know, that the Belgian nurseryman, who propagates his tens of thousands, as a trade affair, will laugh at it. The fact is, that in growing Camellias as trees, and to attract the notice of good judges, and those high in station, and to propagate up to selling-point, with a keen commercial eye, are two matters so widely differing (albeit the subject be the same) as to call for differing practice. But I need say no more this way. Our exhibition-men can attest to the truth of these things. These turfy lumps, then, may be presumed to constitute half the drainage system; and I thus handle them in the case of good-sized shifts. Large and curved crooks are first so placed over the hole, and so overlapping each other, as that three good outlets at least are provided for the escape of water; a very few smaller crooks fall amongst these, but not entirely cover them; and now a layer of these turfy lumps is placed over, but not so closely but that what are termed pounded crooks may be strewn over, so as to fall into every crevice; thus dividing every two lumps of turf, but not covering them overhead; this done, the whole is pressed down close with a broad-ended stick, and now a layer of smaller lumps are strewed over: on the latter is placed the ball.

I have, in repotting, had, of course, annual opportunities of watching the "wear and tear" of this drainage, and I can assure our readers that I have found it nearly as fresh after two years as when first inserted; and that there is no doubt that it will work in the most efficient manner for half-a-score years or more, if requisite care be taken that no extraneous matter gets jammed in when they are set out-of-doors, and that the manure-water be nearly as clear as good ale.

As to the compost, it is chiefly composed of the same turfy material, but chopped tolerably fine by a sharp spade when in a dry or mellow state. Three-fourths of the loam, and one-fourth of chopped, sandy, turfy, heath soil, well blended, makes a capital compost of the most enduring character; for, be it understood, it is this power of *endurance*, or, in other words, of *retaining its organic texture a long while*, on which I take my stand as to growing noble Camellias; in this respect it will be seen that the gardener's object differs from the nurseryman, who merely wants to make a smart saleable plant in little time. If the loam is very sound, very fine sand may be added to ensure porosity, or even pounded charcoal, but the Camellia seems to feel quite at home in loamy organic matter if possessing enough sand to prevent what is termed souring in the soil.

In potting, I continue cramming in turfy lumps as opportunities occur, taking care to shake a finer compost amongst them, and in all cases to secure about a couple of inches of this finer compost over the lumps to finish with; the latter proceeding I consider necessary, as it serves to divide the water equally in its passage, and, indeed, renders the surface less susceptible of sudden atmospheric changes, and provides against sudden droughts.

Now, as to this liquid-manure which I think of first-rate importance for the production of fine blossoms with a dark shining foliage. For my part, I care little about nice blossoms, unless accompanied by that deep, rich, and glossy tint, for which the Camellia-leaf under first-rate culture is so famous. I have used various liquid-manures, both singly and in combination, but I think "Gibbs' Peruvian," is not only complete in itself, but the most effective. But it must be observed, that a little suffices, and indeed so it ought, for it is somewhat costly in these times. I water my Camellias myself at all times. I like not to trust any hobnail fellow with this matter, and I therefore know full well how little will suffice if almost constantly administered. I certainly do not weigh it out; I have no occasion in this matter. I can tell instantly by the frothing of the water in the water-pot how the quality stands. But I will venture to affirm that I do not use an ounce to a gallon. But I use it almost constantly, from the period when the blossom buds are three-parts grown, until they have nearly ceased to make their young wood, when I not only cease manurial-waters, but apply a very limited amount of ordinary water.

The guano is stirred up in a vessel for the purpose, and a little quick lime added; this soon clarifies it. It is, however, necessary to rack it off two or three times, and, if any difficulty arise in getting it clear, we simply add more water, and rack it off again; clear, however, it must be. I may here observe, in order to dispel any fallacious ideas that may arise as to the use of Guano water, that in its application to Camellias, in pots or tubs—I had almost said to pot plants in general—there can be no question that a *special mode of potting* must be resorted to. After all the clarifying we can practice, all liquid-manures have a tendency to clog the soil; that is to say, to prevent that free ingress of the atmosphere which is so necessary to the welfare of the roots, and to prevent that free percolation, or egress of moisture, which creates, as it were, a demand for atmospheric action; to say nothing of the ill effects on the very texture and organism of the fibres, produced by surplus moisture too long retained, and, by consequence, become stagnant and corrupt.

I may here observe, that I this day measured blossoms of the *Camellia Rossii* at least fifteen inches in circumference, and some of the *C. elegans*, about the same size. In spite of all the fine, new kinds, what a fine thing is *elegans*? A model for a first-rate Hollyhock. It is well named *elegans*, and the original raiser ought to be proud of it. *C. imbricata*, too, is still a fine thing; and as for *C. triumphans*, with its peach-coloured blossoms, what a bouncing affair! We have one called *Alcmene*, a fine peach-coloured thing, raised by the late Dean of Manchester; that talented gentleman, so often named by my friend Beaton, in connection with Bulbs and hybridisation; this is little known. We had it from Spofforth some years since, and it is very often a most beautiful and symmetrical thing.

R. ERRINGTON.

MEETING OF THE LONDON HORTICULTURAL SOCIETY.—21ST FEBRUARY, 1854.

In my account of the last meeting, I told our readers that there would be a grand sight seen here to-day—specimens and drawings of the Duke's Tree—*Welling-tonia gigantea*; and the Society announced another grand sight which would come off at the same time and place—specimens to show the "relative quality of Deodar and Cedar of Lebanon timber, by specimens from India and from Lebanon itself." All young gardeners and governesses ought to gather "specimens" of all plants which come in their way, in

flower, in order to learn and mind the names of them, and to be able to tell such names to the rising generations: not such *specimens*, however, as the Society had on view from India, as we shall see presently.

Whether it was from a desire to have a sight of even a dried branch and a picture of that gigantic tree which is to commemorate the great Duke, or to hear of the great national advantages of planting all the knolls in England, and all the hills in Wales, in Ireland, and in Scotland, with the Deodar, I cannot tell, but I think they could not have brought together a more high or more respectable company if they had advertised that the Emperor of Russia and Omar Pacha were to play a game at cribbage in the Egyptian Hall. I never saw such an in-door assemblage of horticulturalists before. I was glad to see Mr. Appleby look so well, and so busy noting down from the Lecture on the merits of the Deodar, for his Essays on Forest-planting, no doubt; he also booked a new Orchid that was there, but he passed over an extreme novelty in the half-hardy bulb way, with a nod, as much as to say, "do not you wish you could tell the name of it?" and he turned to a collection of most beautiful Cyclamens, all crosses, and all of them all but quite new to gardeners. One pot of a new Cyclamen had 254 blooms wide open, besides buds, and those that were going to seed.

Then, as to Fruits; Her Majesty sent such as nobody ever sent before to that room, two splendid Pine Apples of exactly the same size, the same looks, and the very same weight to the split of a hair, that is, a match pair, each weighing 6 lb. 4 oz.; and the two crowns could not weigh 4 oz. between them. It was remarked of them, that if they had been made in a mould they could not come out more alike; add to this, that they were the very best kind of Pine known to us—the *Smooth-leaved Cayenne*—and that the plants which produced them were only suckers this time last year, but chips of the old stools, no doubt, rather than ordinary suckers; yet who could do so much with the best *Black Jamaica*, or the second-best, or worst *Montserrat* Pines, seeing that *Envilles* and *Providencee* Pines are out of date. After these, there were fine specimens of the best of all Black Grapes, the *Barbarossa*, and as fine dessert Pears as we ever had at this season, notwithstanding the bad season for all sorts of keeping fruit.

But let us begin with the Flowers to describe the whole in the order in which they stood on the tables. First of all, there was a large specimen of a new Orchid from Assam, sent by Mr. Veitch—this was a *Cypripedium*, in the way of the old plain-leaved one called *Insigne*, but as large again in the flowers, which are of a brighter colour; the habit of the plant is also much stronger; there were seven large flowers open on this plant and others coming. Mr. Jackson, of Kingston, sent another Orchid, as good as new, being the lovely *Barkeria elegans*, at last; the flowers are about the size of those of *Barkeria spectabilis*, or about those of *Dendrobium nobile*, a better-known plant; the colour of the sepals and petals deep lilac on the back, and lighter on the inside; all over something of that delicate tint which is seen in the lilacy portion of a *Dendrobium nobile*; the lip is large and French-white, with a broad blotch of intense purple about the middle of it; the column lies flat on this lip, advancing just to the margin of the blotch, and ending like the head of a fish—say a small pike, with two dark spots just where the eyes ought to be, and a third dark spot to represent the mouth. You could not look the flower in the front without imagining something of this sort; all the colour is like pure ivory, with these markings, and a little streaked with light purple along the back—of the little fish—altogether, it is an exquisite gem, worth, perhaps, about a guinea the inch. There was a small plant of *Barkeria Skinneri major*, also from Kingston. This I have seen in flower

since last November, and, as I said before, they find no sort of difficulty in growing and flowering these tiny Orchids, but they keep them much cooler than most growers, and they grow on nothing so well as on bare chips of wood quite close to the glass, on a north aspect; it would pinch one's fingers to hold them so near the glass this cold winter, yet a score or more of these *Barkerias* were in bloom there all the time; but the great demand for them has thinned the roof sadly.

The same firm sent an African bulb, which they bought as a new plant, but by some mistake it turns out to be what I believe is *Veltheimia viridifolia*, and which comes very near *Eucomis punctata*. I have grown the two in a front border, and found them nearly hardy; at least, I could always keep them with coal-ashes and an empty pot turned over the bulbs in winter.

Some of our readers may recollect about the new seedlings of *Cyclamens*, which I described at one of these meetings this time two years; the plants have never been touched since, and now it is hardly possible to conceive how pretty two specimen pots of them looked to-day, at this meeting, just such things as a Duchess would like to see on her work table, where they would be just at home and in keeping with all around. One pot had 254 flowers open in a diameter of twelve inches, and every one of them stood upright on a rigid stalk, and there was not the eighth-of-an-inch of difference in the height of all that mass of bloom, so that a house-fly might walk all round on the top of them, stepping from flower to flower, without ever using his wings at all. The tops of the flowers could hardly be five inches from the rim of the pot, and the leaves are numerous, but small accordingly. The colour is a delicate French-white, getting a little deeper at the eye: then, it stands as clear as anything that this is an entirely new Cyclamen; and so it is, and a real cross, too, between *colum* or *vernum* and *persicum*, and the name is *Atkinsonii*, after Mr. James Atkinson, of Painswick, near Gloucester, who made the cross, and got this, and many other fine varieties of the same family, some of which, if not all, are now on sale in London. But I must describe how Mr. Atkinson managed his plants, for I was lucky enough to get introduced to him, and once the ice is broken, there is no more ceremony about flowers and their possessors from her Majesty downwards.

First of all, Mr. Atkinson is a *practical* amateur, who has retired from the busy scene and enjoys himself—as all practical men ought to do as soon as they are able—in his own way. He has travelled abroad, and seen how the Cyclamens do in a state of Nature: and he told me that he often found them growing most luxuriantly among broken limestone and other rock fragments, where all the earth they could reach was from decayed leaves, drifted in among the stones from the neighbouring forests on the Swiss and Italian Alps; that these accumulations of rotten leaves formed a kind of cement, to fill up the fissures among the stones and broken rocks; that the bulbs, so to call them, might appear, in the hot season, to be roasting among the hot stones; but, that from the nature of the situations, the dead leaves and stones among which the roots penetrated, the latter were never dry, winter or summer; and, moreover, that in the wettest season, no more water could lodge among these roots than if they were hung up in a sieve. His practical eye saw at once how all this could be imitated at home, so far as to improve on Nature in the wilderness. He had pots made on purpose for them. These are eight inches deep, twelve inches across the top, and eight inches across the bottom. The first two inches of the bottom he filled with small pieces of soft stones, with a few clean leaves mixed among the stones; then, nearly three inches of light, rich compost of rotten leaves and good loam; then, four bulbs, at equal distances, in each pot: and,

last of all, the spaces between the bulbs are filled up with the same compost, the tops of the bulbs being just covered and no more. Perhaps it will be ten years before they want anything more doing to them, except a fresh surface, now and then, for the look's sake. He keeps them in a cool frame; and last December, the two pots he showed to-day were so hard with frost, that he could not break the surface with his finger; but they received no hurt.

Each pot, when exhibited, was plunged in a fancy willow basket, made to suit, and with two handles; the whole surface of the baskets and pots were covered with green moss, the leaves and flowers coming through as from a sward, a nice hint for how to place such plants on a lady's fancy table, or anywhere through the rooms, but for the wicker basket use glass or china vases *made to suit the pots*, not as one-half of the great folks do now-a-days, first buy their ornamental vases of all earthly and unearthly shapes, and then tease out the gardener's life about getting pots to suit their most foolish whimsies, just as half-crazy people shape their flower-beds first, and then think about the kinds of flowers, or as we in the country sometimes do, put the cart before the horse.

Mr. Henderson, of the Wellington Road, sent a collection of seedling *Cyclamens*, consisting of thirteen pots, and every one of the varieties seemed to me to be really good, new flowers; besides the varieties, there were the old *Persicum*, and the sweet-scented *Persicum*, sent probably as a ground for comparison. The whitest of the seedlings is called *Persicum album*, a very large flower, pure white all over *Pallidum*, the next whitest, is nearly white, with a pale purple eye. A very singular one is doubled in the *divisions* of the flower, there being seven divisions in each flower. Another, called *Striatum*, has a white ground and purple eye, like *Persicum*, and streaked all over with lines and blotches, like the markings on the new white Japan Lilies. The next is *Carneum*, a large flower with a blush flesh-colour all over, and a deep purple eye. After that shade comes a deep rose-coloured one called *Rosum*; and deepest of all is *Rubrum*, a large, deep blood-coloured flower, particularly rich. I think there was one, if not two, of the dwarf French-white *Atkinsonii* among them. The ladies so crowded round this beautiful group after the meeting that I could not catch all the names, but I am quite sure of all I have named.

Besides these, there was a pretty good specimen of the old *Cyclamen persicum* in a 32-pot, with sixty flowers open on it, and the bulb was entirely out of the soil, and the top of it was higher than the rim of the pot. I am not quite certain that I am right in believing that all *Cyclamens* ought to have a bulb just covered in the soil, but I think they ought, and this specimen plant did not alter my old opinion. The reason for keeping up such bulbs, and all true bulbs above the soil, is to make mere room for the roots, but what is gained one way for the roots is more than lost by the exposure of the bulbs. This I have always maintained, and Mr. Atkinson's pots came in to confirm my preference.

Thyracanthus rutilans was here again from the garden of the Society, the same plant that was at the last meeting, and in still better feather. It is a valuable thing for country gardeners. They also sent two of Fortune's *Azaleas* from China, *squamata*, a deep peach-blossomed kind, which, like the Peach, flowers before the young growth begins, a very useful tint, shape and habit to break a new strain in the old Chinese kinds, which run so much into one strain. I read of this plant as of no great account, but I never saw it in bloom till now, and I must say that some writers have too many eyes, or no eyes at all. There is a true foundation for a distinct race of garden crosses; a far better pollen parent than either *Mirabilis*, *Esquitta*, or *Optima*, and yet it

must be passed over because it wants the trouble or pleasure of the cross-breeder.

Azalea obtusa, another of the new ones sent home by Mr. Fortune, with a small crimson flower, will please many sooner than *squamata*; but it is of much less value, as we cannot effect much improvement by it, either as father or mother.

We import silk and cotton, Saxony and Spanish wools, in woolly bales of no inviting aspects; but see what beautiful dresses we get out of them! and it is just the same with wild flowers—so much raw material; we only want the manufacturers to make what kind of flowers we want, and, happily, they are becoming more numerous every season.

There were also nice plants of *Begonia manicata*, and a cross seedling from it, from the garden of the Society, together with *Epacris onosmiflora*, *Polygala Dalmatiana*, *Acacia lineata*, *Centradenia rosea* and *floribunda*; the latter much the best; *Echeveria retusa*, *Correa Goodii*, and a few others of these useful late winter-flowering, or early spring-flowering plants, which deserve a place in every collection, for the time of their flowering is when flowers are scarce.

Who would think that a Crocus in a pot could make a sensation in the heart of London? But so it was, and that, too, among ladies from the country, come up for the "season." I could not get near it for a long time. It is called *Sir Walter Scott*, and is the largest Crocus you ever saw or heard of—a pure white ground, and full of light violet bands all over. A bed of it would beat a bed of Tulips, if they could be seen at the same time. From the name, I should take this Crocus to be a garden seedling; but, as this Society does not pretend to be florists, they must have had it from some one in that line; and, let alone their giving prizes to aspiring florists, it is a good sign to see them sending florists' flowers of the first class from *our own* garden. Patience does wonders everywhere—patience turned the very Austrians to join with the "maritime powers" in a just cause. I only wish I had sufficient patience to be a florist, and I would join the best of them, hand and glove, to bring about what I can see, even on the surface of things.

Wellingtonia Gigantea—As was promised at the last meeting, there were drawings of this splendid tree, exhibited by Mr. Veitch, as well as dried specimens of the branches from young and old trees, with fruit cones, a piece of the bark, and a sample of the wood, all of which were gazed on with wonder after the lecture on it was over. Just think of a tree 29 feet in diameter, and multiply that by three to find the circumference, as we used to say at school, and you would all wonder. The drawing of this tree in the "Illustrated London News," and even the one here to-day does not give one any idea of the beauty of the *form of growth*. It is from the dried specimens of the branches only that any of us can form an idea of this vegetable wonder. I fingered these specimens over and over, and the nearest idea I can give of it, is to say, that the leafy growth on branches of old trees is very near that growth in *Cupressus flacida*, and on the young wood, more like the growth or leaves on *Cupressus filiformis*, that is, with sharp prickles to the minute leaves in the young growth, and that style of foliage on an old plant of *Cryptomeria japonica*.

Deodar.—It was, probably, from the announcement respecting the Deodar that so many of the country gentlemen assembled at this meeting. Our own Editor has shown lately that this was the Cedar with which Solomon built the Temple at Jerusalem; and those who understand the differences of different woods, who had seen the Deodar in Indian temples, bridges, and all sorts of buildings, have told us, long since, that there is no wood so good and durable as that of the Deodar; but

some great people would not believe this, and threw dust in the eyes of those who did. But if seeing is believing, any respectable person may now see what kind of wood this Indian Cedar is, by calling at the rooms of the Society in Regent Street. We had a plank of it in the room, cut from a young tree in India, it was eighteen feet long, four feet six inches wide, and four inches thick, without a knot, and hardly any sap wood; it smells delightfully when they burn it, and even when it is worked by the carpenters it perfumes the whole place. We had a series of Indian drawings showing the range of the Himalayas, the Deodar forests, with temples and all sorts of buildings made of this wood in the foreground. Those who did not know it before, or who did not learn it from Dr. Royle's illustrations of the botany of this range, may be told, that the climate where the Deodar grows to the greatest perfection is very much like the climate of the Mervan range, in Argyleshire, in the west of Scotland, only that the warm season begins two months earlier on the Indian range; but as to wet and dry, cold and dreary, snow, sleet, rain, and hail, thunder, lightning, and all, there is no difference between the Scotch hills and Indian mountains, only that the thunder is louder in India, so that wherever the Larch will grow and thrive, the Deodar will do the same, and is a much faster timber-making tree, and the wood is superior in every respect to that of Larch; but Mr. Appleby has booked all that part of the subject, and we must wait his turn.

D. BEATON.

GOSSIP ABOUT VARIOUS MATTERS.

DRYING-UP THE FOLIAGE OF PLANTS.

"I HAD a few nice plants, Geraniums, best kinds; Cinerarias, ditto; a few Epaeerises, Chorazemas, &c., and being anxious to grow them well, I spared no pains on them. In the late frosty weather the temperature ranged at night from 45° to 55°, and during sunny days I gave air as freely as kept down the house to not more than 5° higher. In fact, I do not see how you could have managed them better, and yet I am so annoyed, the hard-wooded plants look sickly and as if they were scorched with the hot air of a furnace, and many of the best and youngest leaves of the Geraniums have been scalded, as if the steam of a boiling tea-kettle had passed over them. I watered from a cistern in the house; and to my surprise, though some authorities said, "Water once or twice a-week," I found my plants dry every morning. I think there is some *little* thing wrong; do explain what it is; and then I shall not mind my present disappointments."

Most willingly. No doubt, you tried to do well, and there is always hope in the men or women who "will not give up." Bruce learned perseverance from a spider forming its web. Mungo Park gained self-reliance, and a firmer trust in Providence, by the sight of the tiny green moss in the desert. Life is an aggregate of *Littles*; not the great striking episodes of existence, but these next-to-imperceptible *Littles* alike form and demonstrate human character. The keener the observation, the more will this truth be apparent. Look at that boy! Mark with what new fledged zeal he attends these pretty window plants, watering the roots, sponging the foliage, giving them air and sunshine according to their needs. But a fresh attraction presents itself; the plants are comparatively forgotten; they meet, unprotected, the mercies of a frosty night; the wreck is huddled into a corner; gardening is abjured for an age, as other once favourite pursuits have been; and if you follow that youth into the world, you will find, that unless influenced by other minds, he will be a thing of

fits and starts for life. But glance over the way, at that lad, the owner and regulator of that sweet window balcony, that passers-by pay homage to as a gem of taste and beauty. He could tell you of the tricks of Mr. Frost; of disappointments he has known; of failures he has experienced; of bright hopes of bloom and flowers, not merely *deferred*, but scathed and blasted; but, instead of searing his mind into a sort of contemptuous passiveness, they whetted his spirit to increased intelligent effort and persevering exertion. "The boy will be father to the man." He may never be distinguished for wealth; his name may never be whispered amid the exclusive castles of society; for, even in a golden age, he may place no absorbing value on either; but, unless greatly changed by deteriorating influences, men will place the fullest reliance in his indomitable spirit and unswerving perseverance. No stick-in-the-mud will he be. No mole-hill difficulties will ever swell out into impassable mountain barriers with him.

Two *little* things would help to produce the result complained about. General rules are excellent things in their way; but they are chiefly valuable when an intelligent judgment brings them to bear on varied circumstances. The temperature referred to was quite proper for a *warm* greenhouse, and with an outside temperature ranging from 30° to 40°, no harm would have resulted from an average temperature of 50°. Even the plants would not have suffered much at that temperature in a sharpish frost, if by covering the house you so far checked the radiation of heat, and the evaporation and the loss of moisture. But as you do not speak of any protection, and whether you use flues or pipes, do not say anything of evaporating pans upon them, I can easily imagine why you found it necessary to resort to the water-pail often, with an inside temperature of 55°, and an outside temperature of from 20° to 10°. By an inordinate use of fuel, you not only dried the moisture out of the soil of the pots, but dried the air in the house, which thus sucked moisture out of the stems and foliage, and then that air—lighter from heat, and lighter from holding moisture as vapour—ascended to the roof, where the moisture was either condensed into ice, or trickled down the sash-bar, or the air thus moistened found its way out by the laps, and other air, cold and dry, found entrance. This process alone, kept up for any length of time, would not only demand frequent waterings and syringings, but, even with these would exercise a debilitating influence on the constitution of the plants.

But this would be greatly increased when the second *little* error in the circumstances was committed, (and committed very frequently by those who should know and practice better), namely, giving so much air after such a cold night, merely because the sun shone bright, though it might be freezing sharp all the time in the shade. You thus introduce a cold air, parched enough to chap and roughen your own hands and cheeks, among your nice plants that were receiving a moderate roasting the previous night. But what is to be done? The health of the plants, economy in labour, and economy as respects the fuel heap, point to one practice. Those who read what has been said about protection will see one remedy. Failing that, the plants, in severe weather, would be more comfortable for short periods at 38° than at 48°, let alone 58°. Even at that temperature some evaporating pans on the heating medium would be useful when there was an average of from 20° and onwards between the internal and external atmosphere. At this temperature there will be little drain on the juices of the plant. Besides, at this comparatively low temperature at night, the plants will stand an amount of sun heat without much or any air, which they could not do if the heating medium was hot. The less air admitted during such dry, frosty weather the better,

unless care is taken to have it heated and moistened before coming in contact with tender plants. Very little fire should, therefore, be put on such houses in a morning until you satisfy yourself that there is no likelihood of the sun shining; ever keeping in view, that the sun-heat is the best as well as the cheapest. With cool pipes or flues, little air would be required in very cold, frosty weather during the two last and the two first months of the year. If the sun should come strong, when, unawares, the pipes or flues are hot, instead of letting in great blasts of air, it is much preferable to draw the fires out. Syringe the house, paths, &c., and, if necessary, shade the house, or even throw water over it with the syringe. If the sun is likely to continue, the water may be slightly tinged with whiting. *The worst* of the latter plan would be, that as dull weather might soon succeed, the house would be darkened, and would require a little labour, or a good shower to clear it all away. With a night temperature of 40°, or, if higher, with means secured for giving moisture to the air, otherwise than from the soil and stems of the plants, the house may rise from twenty to twenty-five degrees from sun-heat, for a few hours, and the plants, in a keen, frosty air, would be better without opening the sashes than with it. But, if that must be done, and there is no way of ameliorating the air before admitting it, give but a small quantity at the highest part of the roof; and though there the air that escapes will be the moistest as well as the hottest, the air admitted will also be somewhat moistened and heated before reaching the plants, and all such scalding and burning will be avoided. Much of all the anxiety will be guarded against, so far as all greenhouses are concerned, by never allowing a strong fire-heat and a powerful sun-heat to act together. When seeing plants exposed to great and sudden extremes, and knowing the consequences that are sure to result, though some manifest it sooner than others, I have thought a good lesson would be given if the perpetrators were snatched out of their warm bed some keen night, and kept in the open air for an hour without the luxury of clothing.

PRUNING AND POTTING EPACRISES.

"I have some nice plants (*impressa*), that have just finished blooming. Should I prune off the long shoots now, or wait until I pot them? I have nothing but a greenhouse. My Epacrises are not looking healthy. The flowers have opened moderately. I think the soil is in bad order. I could give the plants a little heat in a pit. Shall I prune and fresh pot, and get them to grow freely?" The answer to both must be based on the same principle—never to give a check to roots and branches at once, if it can be avoided. Recollect, there is a constant reciprocal action going on, and, therefore, when a check or mutilation takes place in one part, there will be an effort made by the other part to replace or repair the injury. Here are two Thorn plants; you take up one, prune it down, and plant it again; the other you leave in the ground, after pruning it back in a similar manner. Have you any doubt which of these would grow the most vigorously the first season? Here are two nice Geraniums, in August or September, that must be cut in and repotted for the following year. Cut down one, and repot, by partly disrooting, and thus give the whole plant a sudden check: prune in the other; leave the strength in stems and roots full opportunity to exert itself in forming new branches; and when these are about an inch in length, shake the old soil from the roots, prune them a little, if necessary, and bring these healthy young shoots to react, in turn, upon the forming of fresh and vigorous roots. Will the result ever leave you in doubt which system to adopt in future? Just so with these Epacrises. In a greenhouse, the month of March or April will be soon enough to prune the

young shoots freely back to within a bud or two of whence they come. Then they should be kept in the warmest and closest place; and when the young shoots are growing away freely, and when from an inch and onwards in length, then is the time to repot them, merely picking out a little of the most exhausted soil, and doing as little injury to the roots as possible; keeping the plants a little shaded for some time afterwards, giving them what incentives to growth you can afterwards—for the plant possesses a high temperature and a clear sun in Australia—and taking care to have the wood well ripened in September and October.

The last inquiry I would give much the same answer to. Even although the soil was a little sodden, and a worm had got into it, I would prefer getting the slimy fellow out, by sending a small bit of wire through the ball, and re-arranging the drainage, and then cutting down, and having fresh shoots started before repotting. If, however, the soil was in a very bad state indeed, I would repot at once, very likely in a smaller, clean pot; but then I would do little to the top until the roots were working freely in the fresh soil, and then the pruning back would be effected. During the whole of this process, a little shade, and an increase of temperature, would be desirable. By this latter simple mode many a very sickly plant has been restored. By potting and pruning at once many such plant has at once gone to its final resting place. During the summer, whilst growing, the whole tribe likes heat and moisture. Hence, when there is no other house—such as a vinery, peachery, or even the cool end of a pine-stove—a cold pit, kept warm and moist after May, by giving, comparatively, a small supply of air, will suit them better than a greenhouse. Wherever grown they must be fully exposed to sun, and be saved from drenching rains in September, and be housed in October. Need I add, that fibry peat should form the constituent of the soil, with an addition of silver sand, broken pots, and charcoal, to keep it open.

LARGE GERANIUM PLANTS DYING.

"What can be the reason?" I cannot say, except it be the common result of all organised existence that do, or are made to live *fast*. I, myself, sent some queries respecting such misfortunes, but no answer came. My impression, then, is, that when we grow large specimens, in a short time they as prematurely decay. I found this to be the case when coaxing extra rapid growth by adopting the *one* or *large* shift system. I have lost some large Geraniums for several years. Several Fancies went at the collar, with heads from three to four-and-a-half feet in diameter, and they could not have been more than four years old from the cutting. The Fancies seem more liable to this than the more succulent kinds. We must just be content, I suppose, with smaller and younger plants.

LOSING PLANTS.

"Do you never lose any plants that you have resolved upon keeping? We should not feel so disheartened by our losses, did we know that you and your coadjutors experienced at times a similar misfortune?" Well, be encouraged, by all means. I, even if I did not venture to say *we*, could give you many a chapter on failures. The fact is, that there are few advices I could tender but have been dunned into my own brain by a fair spice of disappointment, from which I would willingly relieve you. Even this last winter I have not been free from them, especially in two instances. The first had reference to *Calceolaria amplexicaulis*, a favourite of mine, because of its soft lemon colour, and a free bloomer when rightly treated. I lately described how my *Calceolarias* stood on a north border, uncovered for ever so many weeks, but none suffered except this *amplexicaulis*, and of that I have not got one healthy

plant, and fear I must abjure it for a season. I knew very well it was tender, but did not know that it was so much more tender than others, most of which never looked better. My second misfortune was with a lot of beautiful plants of *Humea elegans*, that stood in a cold pit well protected. Everything else escaped, but they were destroyed. This mishap was worse than the other, as I had a place for every one of them, and the whole course of planting must be changed for the want of them. I had previously kept them in cold pits, but the plants had been better hardened-off, less luxuriant than they were this season, and the frost had been less continuous and severe. Now, this will teach me the importance of getting such plants, if possible, in another year, by the middle of November, into some receptacle where they can be kept airy and cool, and have a little fire-heat in severe weather. This is just what I intended doing this winter, but the frost came so severe and sudden that I thought moving the plants would be more injurious than allowing them to remain well-covered where they were. This double loss may be a warning to others, and, therefore, worth mentioning.

R. FISHER.

THE ANTIRRHINUM.

(Continued from page 421.)

Propagation: by Cuttings.—In last week's COTTAGE GARDENER I gave pretty full directions how to raise new and improved varieties of this charming flower. As a matter of course, whoever either raises a superior variety from seed, or purchases from a florist either new or established good varieties, is naturally anxious to increase such. They may, to a limited extent, be increased by division, but that mode is slow and uncertain; whereas, cuttings strike so easily that the grower need not resort to any other method than that by cuttings.

There are two ways by which cuttings may be rooted; first, in pots, placed in heat; and second, under a hand-light in a shady border. The first may be resorted to where the proprietor has the convenience of a hotbed with a frame set on it, or a regular propagating house. With either of these conveniences the way to proceed is as follows:—

Prepare a cutting-pot (four or five-inch diameter) by well draining it, that is, place a large crock, or an oyster-shell over the hole at the bottom of the pot, then place a few lesser pots/berds over that, and upon them at least an inch of still smaller, covering the whole with a thin layer of moss to prevent the soil from choking up the drainage: the whole to occupy fully one-half of the depth of the pot. Upon this good drain place as much roughly-sifted light compost, formed with equal portions of loam, leaf-mould, and sandy-peat, as will fill the pot to within half-an-inch of the rim, give it a gentle shake down, but do not press it hard; then fill up the remaining space level with the rim, with rather moist, fine white sand, stroking it off level with a straight edged stick; then proceed to choose the cuttings. The best are the short side-shoots produced below the spike of flowers, or weak shoots growing from the sides of the plants. Avoid strong, coarse shoots, these are apt to damp off on account of holding so much sap. Prepare the cuttings by dressing off all the lower leaves, leaving only three or four if they are small, then give a clear horizontal cut at the joint. It is advisable always to make the cuttings very short; indeed, this remark applies to all cuttings of soft-wooded plants. I, this spring, lost the greater part of a crop of *Verbena* cuttings, by my man putting them in too long, with a piece of old wood at the bottom of each. The few that struck made roots from the upper part of the cutting. Let my mishap be a warning to the propagator. There

is nothing gained by large cuttings, for if they do strike they are much longer in doing their work. If cuttings are plentiful, then fill a pot with one kind only, placing the label in the centre, and the cuttings close round the side of the pot, just allowing room enough for the leaves of each cutting to have elbow room. As a general rule, I have found for such small cuttings half-an-inch between each is ample space. My good friend, Mr. Beaton, in his excellent paper on striking cuttings, mentions that he accidentally found out that cuttings do better if put in before the sand is wetted. I agree with him on that point, having practised it for some time, that is, for soft-wooded plants only. Such things as *Heaths* and *Epacris* require the sand made fine, by watering, before inserting the cuttings of such hard-wooded plants.

To return to the *Antirrhinum* cuttings. When cuttings are scarce, and not sufficient to fill the pot, then insert a label between the varieties, so as to distinguish them at the time of potting them off. Proceed till all intended to be propagated are put in, and then give them a good watering, and as soon as the leaves are dry place them in the frame, or in the propagating-house. Shade diligently and effectually from the sun, and keep the sand moderately moist. They will soon bear the sun's rays for an hour or two in the morning and afternoon, and with this care and attention every cutting ought to be rooted in a fortnight or three weeks. The season for putting in these cuttings may be extended from April to August, but the best time is about the middle of July, because then the plants will give a good supply of cuttings, and they will have time to get well established before the winter.

Immediately they have emitted roots they should be potted off singly into three-inch pots, in the same compost. Nip off the tops as soon as they are potted, to cause them to make bushy plants. Place them, when potted, in a cold frame, shading them from the sun till fresh roots are made; then give air moderately at first, and more freely as they can bear it; they will then be ready to plant out in the blooming-bed, or, if very much valued, they may be kept in the pots in a cold pit till spring. The method of striking them under hand-lights is simple and easy:—Prepare the border for them (behind a low north wall) in the same manner as described for the pots, with the exception of the drainage, unless the border is wet, then it will be advisable to drain it also. Raise the border two or three inches above the ordinary level; make the sand smooth, and place the hand-lights upon it, to make a mark to show where the cuttings are to be planted; make the cuttings exactly in the same way as described above for those in pot; then, with a small stick, insert the cuttings in rows, within the space marked by the edges of the hand-light, and when all are planted, give a gentle watering, leaving the hand-lights off till the leaves are dry; then place them over the cuttings, and they will need no more care till evident signs of growth take place, when the hand-lights should be lifted off for two or three hours every morning, and, finally, remove them altogether, when the cuttings no longer flag with the exposure. In a month's time they may be transplanted carefully where they are to flower. This hand-light method should be put in operation as soon as ever sufficient cuttings can be obtained, because they do not root so quickly, though surely, as those in pots in heat.

T. APPELEY.

(To be continued.)

STOVE FERNS.

(Continued from page 404.)

GENIOPHEBIUM SEPULTUM (Covered).—A very remarkable South American Fern, of great beauty, and very rare. The fronds are lance-shaped and pinnate,

and, when well grown, a foot or more in length. This deserves its designation of a very remarkable Fern, from the fact that the pinnæ, or leaves, are covered thickly with narrow, fringed scales, of a light, hoary colour. These feathery scales give the plant a very distinct and beautiful appearance, so much so that I, or anybody else, may distinguish it amongst a numerous collection many yards off. I fortunately possess two plants of it, and I find it will bear a lower temperature than most other Stove Ferns. The *Adiantum macrophyllum* was quite killed in the same house in which this same *Goniophlebium* is quite healthy and uninjured. This is a remarkable fact, that some plants from hot regions bear more cold than others. I remember the day when the hardy Aucuba, because it came from Japan, was thought to require the protection of the greenhouse, and now it is found, in suitable soil, to be hardier than our common Laurel; and so, I have no doubt, many Ferns from warm climates have a constitution more hardy than we are aware of. This Fern I have increased, though slowly, by dividing the white slow-creeping root-stock.

GONIOPTERIS.

This is a well-defined genus, formed out of *Polypodium*, by Mr. Prest. The name alludes to the lesser veins running in angles, (*gonia*) and *pteris*, a Fern, or, in simple English, the Angular Fern. The species of this genus are not numerous, and grow only to a medium size, never exceeding three feet, and generally not more than one foot in height. The most interesting are

GONIOPTERIS FRAXINIFOLIA (Ash-leaved).—A Brazilian Fern, with fronds two feet long; they are pinnate, and the pinnæ (wings, or side leaves) are smooth, shining, and of a dark green. Many of these pinnæ form little buds at the end, which, in a damp stove, soon put out roots; and, if these are carefully cut off and planted shallow in a pot, under a bell-glass, they soon make good plants.

G. PENNIGERA (Feathered).—Though this elegant Fern is a native of New Zealand, it requires the stove to grow it to its greatest beauty. The fronds are of two kinds, barren and fertile; the barren fronds grow one-and-a-half feet long, are spread open, are pinnate, and the pinnæ are covered thinly with short hairs, and are of a long, narrow shape, like feathers; the fertile fronds are curled up, and grow more erect than the others. The seed vessels are placed in the middle, between the main rib, on the angle of the smaller veins. Increased by dividing the creeping rhizoma. A very beautiful medium-sized Fern, worthy of general cultivation.

GYMNOGRAMMA.

This genus has some of the most interesting and most beautiful Ferns in cultivation, containing the elegant Gold and Silver Ferns. The name is derived from *gymnos*, naked, and *gramma*, writing, because the seed-vessels have no cover. With a moderate magnifier, the seeds may be seen in the cases without any covering. All growers of Ferns ought to have a tolerable good microscope to observe their wonderful conformation. Without such an instrument the greatest beauties of tribe are lost to the naked unassisted eye.

GYMNOGRAMMA CHRYSOPHYLLA (Golden-leaved).—Emphatically said to be "one of the most beautiful exotics in cultivation." Grows plentifully in the West Indies and South America, on stumps of trees and in crevices of shaded rocks. The fronds seldom exceed a foot in height, excepting under high cultivation, in a moist, high temperature. They are bi-pinnate, or twice divided, and the pinnæ are of an oval shape, slightly cut at the edges. The great beauty of this Fern consists in the under-side being covered with a bright, golden-coloured powder. Many a time have I been delighted, on showing this Fern to visitors who had never seen it before, with the

glowing pleasure depicted on their countenances on seeing the bright yellow colour on the under side of the leaves. The upper surface being the usual colour, green, had nothing remarkable about it, but, on turning the plant upside-down, the glorious golden yellow always drew forth exclamations of wonder and delight. Its culture is easy; the only point that must not be neglected is water. This element must be regularly supplied. It seeds freely, and, in favourable circumstances, the seed vegetates as freely. These circumstances are, a constantly moist atmosphere, with a high temperature. I have had them come up, as it were, spontaneously, in the shady parts of the Orchid-house; but the more sure way is to scatter the seeds on some sand-stones, laid on a bed of moss, kept moist, and covered with a hand-light, or large bell-glass. The second seed-leaves of great numbers of *Gymnogramma* are beautifully cut into linear strips, and form almost a circle. By these they may be known from weedy, common Ferns. When they have made the third leaf they should be transplanted into very small pots, replaced under the glass, and remain there till fresh roots are emitted. After that, place them in a shady place, and treat them like their congeners.

G. TARTAREA (Infernal).—So named, I suppose, because the stems are black as ink. As a contrast to the deep blackness of the stems, the under side of the leaves is densely covered with a white powder, hence it has been called the Silver Fern. The fronds are broader at the base than the former species, often tri-pinnate; and the leaves, or pinnæ, are oval, the lowest one divided into lobes. The grand, distinguishing mark, however, is the white powder. Its culture is the same as for the preceding. These are the two species most remarkable in the genus, and the remainder I give the names of only as my space is limited.

G. culomelanas, beautiful black; a Silver Fern; *G. leptophylla* (Slender-leaved); *G. Merlensii* (Merlen's); *G. rufa* (Red Haired); *G. tomentosa* (Hairy).

There are some others, but not particularly interesting; *G. ochracea* is quite a weed in the Orchid-house, and has some little of the golden powder on the stems. It is often sold for the true Gold Fern. T. APPELEY.

(To be continued.)

NOTES ON THE ONION.

THIS useful bulb, on which I purpose making some remarks, has not always received the attention it deserves, neither in its cultivation, nor in the many uses to which it may be applied. The latter subject, doubtless, belongs to the department of some one else; but I cannot help thinking that a sort of morbid fastidiousness prevents its more general adoption at the tables of the affluent; the poor, less fettered by the trammels of society, perhaps, derive more benefit from it: and, assuredly, there is no vegetable grown more really wholesome; and when it is known that the produce, on good ground, amounts to something like the same measure as a good crop of Potatoes will turn up, it becomes a matter of economy to enquire how far it may be made a substitute for that uncertain tuber; and as the seed required for a given space is a much less expensive article than the roots wanted in the other, and the crop being sooner cleared off the ground, giving time for another one the same season, it follows that a good breadth of Onions, in a poor man's garden, is not altogether such a bad substitute for the Potato. The cooking, &c. of these, I would rather leave to more experienced hands, only I feel certain, were Onions more generally adopted, the unpleasantness (real or imaginary) arising from them would be less noticed, and a healthy, nutritious article of food (long kept in the back-ground) restored to its proper place.

In regard to the cultivation of this bulb, the late Mr. Knight held the opinion, that the English summer was not long enough to perfect this production, and that to do so the crop ought to be forwarded a little, by being sown late in the preceding season, and preserved in some way during the winter. This doctrine is, to a certain extent, true; but the inconveniences of the remedy proposed renders that almost as objectionable as the evil to be overcome; besides which, it does not always accomplish that, and Onions, the produce of two seasons growth, seldom keep well—I might say they never do. Mr. Knight's theory, however, was not by any means a vague or useless one, for Onions, forwarded by hot-beds, &c., and planted out in a favourable situation, in a northern or other bleak district, are much improved and their size much increased; while, in such places, it is almost impossible to obtain large, good bulbs, without some such aid, or adopting the biennial growth in some way or other; the most common being to sow a good breadth about the beginning of August, and by preserving them, by covering in some way until spring, to plant them out on fresh, well-prepared ground, taking care to nip out the seed-stem as soon as it appears, and to give them every advantage, in the shape of hand-hoeing, &c., which can be commanded. Another plan, resembling the last, is to select some small bulbs, not larger than Crocusses, from the stores of the previous year, and to plant them in the same way as the last; the produce will be a large, though not a solid description of bulbs: still, for use early in the season they are valuable.

Though the above methods may be advantageously adopted in many cases, and Onions sown under glass in January, and grown there till April, and then planted out, may also be applicable in other circumstances, yet the great bulk of the Onion crop is, and must be, sown when it is to be produced the same year, and, consequently, under such circumstances, ought to be accommodated with everything necessary to forward it, as good ground, well-manured, and open yet not bleak situation, and that good after-culture which tends as much to perfect this as any other crop we know of. However, we will suppose that the careful manager has long ago prepared the ground his Onion crop is to occupy, and that it has been lying exposed to the frosts and other changes of weather which benefit ground so much, and it be sufficiently dry, in the early part of March, to allow of its being trod upon without unduly pressing it; the seed must be sown forthwith, and the most usual way is to draw shallow drills, one foot apart, and to sow the seed very thin in those drills, covering them over after with the rake, sowing, perhaps, a few Radishes at random over the ground as well to draw while young.

Now, this is the best practice when the ground is not too stiff nor wet to prevent its being done at the proper time in that way; but when that cannot be accomplished, then let the ground be marked into beds, and the seed sown broadcast, and covered with soil cast out of the alleys; the result will be scarcely less abundant than by the other way, only, when they are sown in beds, they rarely are thinned sufficiently to ensure them swelling to the size that denotes perfection; but that duty must be insisted on, and the Onions, instead of being cramped together like the blades of glass in a well-bottomed piece of turf, ought to stand perfectly clear from each other, and when full grown they ought not to be touching each other in any way.

It may be worth while to remark, that in common with almost everything else, the number of varieties of the Onion have increased, or said to have increased, yet not to the extent of other things: for the good points of an Onion have not so much attracted attention as the earliness, flavour, or productiveness of Peas and similar vegetables, for the improvement of which so much has been said, if not done. Neither are our Onions dignified

with the title of anyone's name; doubtless, for the reason that they do not like to condescend to patronize an article so opposed to the ideas of poetry or politeness: be that as it may, there are sufficient varieties to select from; and the inexperienced would do well to confine himself to one or two sorts, of which he has reason to believe the seed to be good. The *Globe* is an excellent Onion, and so is the *White Spanish*, but the *Strasburgh* is said to keep better than either; it is, however, smaller. The *Deftford* is also good; in fact, if the seed be suspected, it is better to get a quantity of each, and mix them together, and then sow the mixture. The white kinds are so much alike that no particular difference is perceptible to ordinary observers; certainly, such kinds as the *Blood*, *Tripoli*, *Welch*, and *Silver Skinned* differ entirely from the general stock, and ought not to be sown with them, but the others may be sown as inclination directs. The *Silver Skinned*, being mostly used for pickling, ought to be sown thick, on some piece of poor land, and not so soon as the general crop.

J. ROBSON.

The *Spanish fowls*, part of the stock of Mrs. Lydia Stowe, sold for very good prices, at Mr. Stevens's, on the 28th of February. Lot 151, a very superior Cockerel, fetched £11 10s. The highest sum for a Pullet, was £5 10s. The thirty lots averaged about £2 17s. each.

WEIGHTS OF PEAR FRUIT.

THE different horticultural periodicals of the day frequently attract their readers' attention to the accounts they give of the weights of Pear fruit exhibited at the different exhibitions, but never having met with any accounts either corresponding or approaching to the following, I have transcribed them, under the impression they may be interesting to many of the horticulturists and fruit growers included in the number of the readers of THE COTTAGE GARDENER.

In the month of October, 1834, the Board of Management of the Royal Jersey Agricultural and Horticultural Society, resolved on sending for his late gracious Majesty's acceptance, a collection of Jersey-grown fruit, and the following is a list (with weights attached) of part of the fruit sent—

- 103 Chaumontelle Pears, 88 lbs. 3 ozs.
- 16 Duchess d'Angouleme Pears, 23 lbs.
- 35 Beurré d'Arenberg, 27 lbs. 10 ozs.
- 36 Crassanne, 20 lbs. 3 ozs.
- 2 Belle de Jersey, or *Uvedale* St. Germain Pears, 6 lbs.,
- and 12 *Passe Colmar*, not specified.

There were, also, some remarkable fine Apples sent, of the Golden Pippin, Nonpareil, Pigeonnet, and Court of Wick varieties. The two remarkable fruit of Belle de Jersey Pear, were grown and presented to the Society, for representation, by John Le Couteur, Esq., of Belle Vue, Jersey; the remainder of the fruits being contributed by different gentlemen, members of the Society, feeling interested in its proceedings.

And in 1841, another collection of Jersey-grown Pears were respectfully forwarded for her present gracious Majesty's acceptance, including

- 2 Duchesse d'Angouleme, 3 lbs. 5 ozs., or 1 lb. 10½ ozs. each.
- 12 " " selected, 17 lbs. 6 ozs.
- 1 Chaumontelle, 1 lb. 6 ozs.
- 12 " " selected, 13 lbs. 7½ ozs.
- 1 Crassanne, 1 lb. 1¼ oz.
- 12 " " selected, 10 lbs. 4 ozs.
- 1 Beurré d'Arenberg, 14 ozs.
- 12 " " selected, 9 lbs. 6 ozs.

Here, again, the two monster Duchesse d'Angouleme fruit were again contributed by John Le Couteur, Esq., of Belle Vue, and the largest Chaumontelle and Crassanne, by James Hammond, Esq., of Fantaisie, Jersey, and the remainder in

the same manner as the preceding collection, the weights of the fruits being, in both cases, attested and guaranteed by the honorary secretaries' signatures in the reports of the season.

The following remarks were also included in the Honorary Secretary's Report for the season of 1841:—"The unusually moist season has affected fruit in different ways. The stone fruits, especially Apricots, were shrivelled, cracked, and flavourless. Peaches were few and ill-flavoured. Pears were fine, and of excellent quality or flavour (especially the Crassanne and Beurré d'Arenberg varieties—a fruit, referring to the last, which cannot be too highly prized), and their keeping properties seem to have been much impaired by the humidity of the season. The Crassannes, Passe Colnars, Chaumontelles, and Bergamotts de la Pentecôte (or Easter Beurre), having mostly ripened before the fifteenth of December."

Here I should remark, that the variety of Pear recognised as the Beurré d'Arenberg is the Glout Morceau, under which name it is cultivated in Jersey. There is no resemblance between the two varieties but in the texture of the fruit's skin. The Glout Morceau, which is much the finer of the two, is easily recognised by the vigour of the tree's growth; the wood is also much darker and thorny, and the fruits are (when fine) quinquagonally divided, and elongated at both ends, with a beautiful, smooth, pale green skin; keeping from November to January, according to seasons. The Beurré d'Arenberg is smooth in the wood, paler in colour of the bark; smaller in the size of the fruit, being round at the end; at times a little russety, and ripening at the same season.

Hence, from the foregoing remarks of the Honorary Secretary, we have the gratification of learning, that the ripening season of Pear fruit is in a great measure dependent on the moistness of the season. An useful, though an antecedent corroboration of our present ideas and experience on the subject. We shall learn more about it, by-and-by; patience and perseverance will heal many of the ills arising from the conflict of opinions on this and other useful subjects.

The greater portion of the Pears included in these two short lists were grown on trees budded on Quince stocks, in moist, friable soils; a plan more profitable and preferable to any other I am as yet acquainted with.—C. B. SAUNDERS, *Cesarean Nursery, Jersey.*

THE MANCHESTER POULTRY SHOW.

YOUR notice of the Manchester Poultry Exhibition induces me to trouble you with a few remarks, which, perhaps, may be found worthy of a place in *THE COTTAGE GARDENER*, as well as useful to those in other localities who may be meditating a "first poultry exhibition." There are only about six or eight amateurs here who have paid any attention to Poultry, and being desirous of encouraging and promoting, as far as their endeavours could, a taste in this neighbourhood for "the fancy," conceived the idea of an exhibition. These few amateurs set to work, raised a guarantee fund, which was most liberally responded to by the "merchant princes" here, and in a very few days over £300 was guaranteed by sums of £5 each. That the first Manchester Poultry Show should be worthy of their city, they determined to give prizes equal to those given at other large exhibitions, in order to induce the first breeders in the country to send their birds. I think they wisely resolved not to restrict an exhibitor to one pen of any particular class, thereby giving the amateur the chance of taking all the prizes, if he could, in any particular class. One regulation, I would suggest, should be altered in future shows; it was "no person (with the exception of cottagers) could exhibit without being a subscriber of 10s." This gave him the privilege of showing four pens of birds and having two admission tickets. The reason is obvious: a subscriber of 10s., having four pens, sent inferior specimens to fill up his allowance. There should always be a fixed charge per pen as well as per ticket. Had this been the case here, I believe the committee would have found themselves better off in a pecuniary point of view. The committee are deserving of the highest praise for their courtesy and un-

wearied exertions. I know many of them were in the Free Trade Hall, each day, from the opening to the closing of the exhibition, and suffered severely in consequence of the fatigue. The Amateur Prize of £5, for the best cock of five different breeds, afforded a fine opportunity to breeders of purchasing first class stud birds, and I think is worthy of being copied at other exhibitions. The fine specimens exhibited here showed how exhibitors appreciated this prize. I think the liberality of Mr. John S. Henry, of Woodlands, Crimpsall, a member of the committee, ought to be made known: it was he who so handsomely presented this prize. Although I find he was an exhibitor amongst the Cochins, I regret that his liberality was not rewarded by a prize; but I doubt not that in a future occasion he will be more successful, as he has since purchased some of the best blood in the country. Your correspondent's remarks about the Cochins exhibited are very true; they were, indeed, with few exceptions, "a bad lot." Many of them were sold, the day after the exhibition, at auction, for the most ridiculously high prices for such specimens; and why? because they were puffed off as remarkably short-legged birds, and the produce of poultry belonging to our first breeders. One black cock, who, amongst a lot of very poor ones, had a prize here, was sold, after much competition, for £8 10s. But there is nothing like a good puff for selling fowls, as everything else. Really, Messrs. Sturgeon and Punchard's yards have been very much *drawn* upon for fine specimens and pedigrees. These gentlemen have much to complain of. If you think this worthy of notice, I shall be glad to inform you how "Manchester Poultry" progress.—J. R.

[We concur in the opinion of the writer of the above, that "pen-money" is likely to serve a good purpose in future Poultry Exhibitions, not merely as adding to their receipts, but as affording a useful check against too many entries on the part of a single individual. A graduated scale, after the manner of the assessed taxes on carriages or horses, might aid such a plan. The regulations at present in force, where this restriction is exercised, are notoriously evaded, the names of wives, relations, friends, and servants, who have no *bonâ fide* ownership in the birds, being continually employed to secure the admission of the extra number. A rule that is thus infringed with impunity becomes one of those things that are more honoured in the breach than the observance. We must congratulate Manchester on its late *debut* in the poultry arena, and have sanguine anticipations for its second season.]

HARDY BORDER PLANTS.

ERICA CARNEA.

THIS Heath of "flesh-coloured" flowers is often called *E. herbacea*, the Herbaceous, or the Early-flowering Heath.

It is a little shrubby, or under-shrubby, evergreen plant; is of procumbent habit, and still forms one of the snuggest little bunches that can be introduced into our flower borders, whether as a marginal plant to shrub plantations, a bunched to itself, or as a mixed plant with other hardy herbaceous plants. Wherever planted, it should always be a front plant in the beds from its dwarfness, its height being from six to nine inches.

It will thrive in almost any good garden soil, and in any situation; so that it might be "every one's plant;" but the soil most suitable to it is a mixture of one-half peat, well worked in with one-half common garden soil, and if with a spadeful or two of leaf-mould, all the better. This mixture should be used as a top dressing round about and in among the stems of such plants.

Though it will root from cuttings, like all the rest of its long family—the Heaths—yet, where the old-established bunches are kindly attended to once a-year, keeping their stems well top-dressed, as before said, all its stems that come in contact with the earth beneath or about them will put out abundance of roots, which enables the plant to be readily increased by rooted slips. Occasionally, an old plant taken up affords an abundant increase by division, like other common herbaceous plants.

Although this plant is a native of the Alps and mountainous parts of Germany, I have always found it to flourish best in

a cool soil, or in situations where it never seemed to want for moisture at the root.

It is certainly one of the most hardy of all plants, and one of the prettiest, too. Let the weather come as it may, during its flowering season, storm or sunshine never hurts it. Its time of flowering much depends upon the season and situation, but from the middle of January to the end of March is its usual time.

Its flowers are produced in wreath-like, one-sided spikes. Its oblong blossoms all lapping over each other in a pendulous form, and from the axils of its leaves, which are generally in fours up its numerous stems. The flowers are deep flesh-coloured, with black anthers extending a little longer than the mouth of the corolla; then the white pointal or stigma extends a little longer still, like a tiny beak through the black anthers, rendering the blossom altogether about half-an-inch in length. The leaves are line-like, smooth, half-an-inch in length, and of a dark green colour. The plant at all seasons looks neat in the borders, and at this time of the year is one of the most useful for those who require nosegays, for it is the prettiest hardy out-door plant we have in bloom at this season of the year.

This plant also seems just in its element when planted upon the rockery. Indeed, it is worthy of a place in any part of a garden, whether as an out-door, or in-door pot-plant.

It appears to have been introduced to this country in the year 1763, and is a native of Germany.

As this plant is apt to be plucked or trimmed very much in its flowering season, it rarely requires much cutting-in to keep it within a proper sized bunch to suit the spot it may be growing in, but should such be the case, this should be done as soon as the plant is out of bloom, and if not done before, when the borders were dressed off, a spadeful or two of peat-earth or leaf-mould, or both mixed together, added as a top-dressing. Thus kindly treated, snug little bunches may be seen in the same spots for very many years.

T. W.

ECONOMIC DIFFERENCES IN THE BREEDS OF SHANGHAES.

As I myself am well aware of the truthfulness of a *great portion* of the enclosed statement, and also feel every confidence in the veracity of my informant, I think the results of the trial of two different "strains" of Coehins may be perused with interest by, at least, some of your readers, more especially as I myself could not have accredited the result, had I not known it, and that a regular weekly account has been kept by their owner of the produce.

My friend's "run" embraces three-parts-of-an-acre of very dry pasture land, abounding with clover; at one end is a stable, divided equally with wire-work only, as is, also, the whole of the ground to which the two sets of birds have access; and most certainly neither lot of fowls could by any possibility intrude on the possessions of the others. Each set have nests in their own apportioned part of the stable, to which no one has access except the owner, being kept constantly locked; and as they are fed alike, their advantages are, of course, precisely similar; and, I think, perhaps, no two sets of poultry ever were so fairly tried (without any prejudice) "on their simple utility." The first day in October last, a cock and eight hens of very short-legged and well-built Coehins were placed in one division. These are as good in character, though a little out in colour, as could well be met with, even among the prize pens at most of our principal shows. In the other department, the same number of coarse, long-legged, and spare stilty birds (CALLED Coehins, and lately too generally shown as such) received the same attention. The owner alone fed these fowls, thrice daily, viz., before leaving for business, at dinner-time, and in the evening; the corn being actually "measured in a bowl to each lot." I have been thus particular, to preclude the idea of favoritism. I will, therefore, now content myself by saying, all were birds about the same age to a week or so, supposed never to have laid, being chickens of 1853. It will be seen how exceedingly different the return of eggs, and how much more the tall, spare birds seemed affected by the severe winter than their more compact fellows; whilst the very great regularity of laying of the latter, proves, I con-

ceive, the very best possible evidence that their superiority is NOT the IDEAL affair some would suppose. My friend merely kept them "to see the difference, if there was any," and never would sell either fowls or eggs.

		Well-built and short-legged birds.	Spare and stilty birds.

I am fully aware there is an inaccuracy as to the division of the weeks, but as this did not interfere any way with the returns, I have faithfully made copy of the manuscript, as lent me by the owner. The result determines their owner to use the least valuable lot for the table, and he promises me the result of a similar trial with some pretty good Spanish fowls, tested the same way, on the same walk, and from May-day to May-day following. If spared to see this result, I consider it will be very interesting, as my friend will not allow his fowls to sit, "only wishing FAIRLY to test their egg-producing qualities," and having a better opportunity of so doing than any other amateur I am acquainted with, I feel it certain the returns will be faithfully rendered.

I fear the above will be tedious, but it has been so fairly conducted, I think it conveys really USEFUL information, for which reason I have forwarded it.—EDWARD HEWITT, Sparkbrook, near Birmingham.

BEE-KEEPING FOR COTTAGERS.

(Continued from page 389.)

SECTION 3.—CALENDAR OF OPERATIONS.

INTRODUCTORY.—We will commence our Calendar with March, as then the bees first begin to rouse themselves from their winter's rest. We will assume that the first section of these papers has been carefully considered, and that something is known of the habits of bees; that it is intended to commence a new system; that some portion of the necessary apparatus is in a forward state; and that you are burning with a desire to give your neighbours a wrinkle or two before long. Instead of writing at length the times in the month when the various operations are to be performed, (b) placed before a direction, will mean that it is to be attended to in the beginning; (m) in the middle; and (e) at the end of the month: where no letter is prefixed, the direction must be attended to all through the month. The times mentioned are generally correct: in cold and wet seasons, however, the operations should be performed a week or ten days later than is directed; a little reflection on this point will be the safest guide. We should also state, that we are writing in a garden county, where food is plentiful, considerably earlier than in mountainous and grass counties. According to our original plan, the method of performing the various operations will be detailed in Section 4.

MARCH, b.—The Queen has now been laying for some time in strong hives, the hives should, therefore, be kept warm; to do this, remove pots and glasses from the tops,

and cover the holes with pieces of stout wood, large enough to overlap the holes on all sides; warmth assists the coming forward of the brood.

b. Weigh your hives; if the net weight (that is, the weight after allowing for the weight of the hives and floor-boards,) be less than 12 lbs., feed a little.

b. Change your floor-boards at this weighing; they will, by this time, have very likely become damp and dirty, particularly where condensing has not been attended to. In changing floor-boards, always carefully look for and destroy the small grubs which fix themselves at the junction of the hives and floor-boards.

b. If no water is near, supply some; the bees require it to moisten the pollen wherewith they feed the brood.

As the weather warms, and the bees begin to crowd in coming out, the entrances must be widened; should the weather change and set in cold they should be again contracted.

Look out for and destroy queen wasps; all wasps now about (or rather, that will be about before long), are queens, and the would-be mothers of thousands; kill them all, for wasps are amongst the worst enemies of bees.

Keep everything about the hives trim and clean, rout up ants nests, brush away spiders, watch for, catch, and kill, all moths, slugs, and other vermin; these directions should be attended to all the year round.

APRIL.—The directions given for last month apply equally to this, except as to the floor-boards, which need not again be changed.

The chief danger to be feared now is want of food; the supply obtained by the bees is still scanty, whilst the consumption day by day increases, and many hives that have lived through the winter perish now for the want of a little attention; if the bees in one hive be idle, whilst those in others are all busy, feeding should be at once attended to; idleness, and hanging about the entrance, are frequently attributable to weakness from scarcity of food.

e. Send hives to the bee-keepers from whom you are about to buy, or otherwise obtain, fresh swarms, that all may ready. Before doing so, singe off all rough straw from the inside; they only hinder the bees in their work.

Stock-hives may be bought as late as the end of the month, provided they be moved from a distance of three or four miles. This is, perhaps, the safest time to buy stocks, as all fear of their perishing is now at an end. Care should be taken, in buying stocks, to select prime swarms of the last summer: they may be known by the combs being lighter in colour than older stocks. It will be prudent (unless you can trust the man from whom you are about to buy) to seek the advice of some experienced friend in making a purchase.

(To be continued.)

SEA WEEDS.

(Continued from page 386.)

4. GRACILLARIA. *Grev.*

FROND filiform or rarely flat, fleshy-cartilaginous, continuous; cellular, the central cells large, empty, or full of granular matter; those of the surface minute, forming densely packed horizontal filaments. Fructification 1. convex tubercles (coccidia), having a thick pericarp composed of radiating filaments, containing a mass of minute spores; 2. tetraspores imbedded in the cells of the surface. Name signifying *slender*.—*Harvey*.

1. GRACILLARIA MULTIPARTITA (Much-divided).—A rare and handsome weed, found on our southern shores, very like some of the Rhodymenia in appearance. From four to twelve inches high. Colour a rather deep dull puce or purple.

2. G. COMPRESSA (Flattened).—"Very rare, and thrown up from deep water;" sometimes growing on coral. It has been found by Mrs. Griffiths, at Sidmouth; Mrs. Gulson, at Exmouth; and Miss Turner, in Jersey. When fresh the substance is very tender, but becomes tough in drying. Colour dull red. Frond from six to twelve inches long.

3. G. CONFERVOIDES (Conferva-like).—Not uncommon; growing on rocks in the sea. More than a foot and a half

in length. Colour deep red, and substance cartilaginous; and it does not adhere to paper on drying. The plant may be distinguished by its tubercles, which are large.

4. G. ERECTA (Upright).—On sandy rocks near low water; bearing fruit in winter. Fronds numerous; one or two inches high; of a red colour. Very rare.

ORDER 12.—CRYPTONEMIACEÆ.

"Purplish or rose-red sea-weeds, with a filiform or (rarely) expanded, gelatinous or cartilaginous frond, composed, wholly or in part, of cylindrical cells connected together into filaments. Axis formed of vertical, periphery of horizontally radiating filaments. Fructification 1. conceptacles (favellidia) globose masses of spores immersed in the frond or in swellings of the branches. 2. tetraspores variously dispersed."—*Harvey*.

1. GRATELOUPIA.

Name in honour of Dr. Grateloup, a French algologist. "Frond flat, pinnate solid, and dense in structure."

1. G. FILICINA (Thread-like).—Very rare; growing on rocks and stones in the sea. Colour dull purple, sometimes greenish. Fronds of British plants seldom more than two inches high. In appearance very like *Gelidium coraceum*.

2. GELIDIUM.

"Frond, between cartilaginous and corneous, plano-compressed, distichously branched, branches pinnate or bi-pinnate, pinnae spreading or horizontal, obtuse capsules spherical, immersed in the extremities of the ramuli."—*Greville*.

1. GELIDIUM CORACEUM (Horny).—In rocky pools, and on rocks in the sea; very common. A most variable plant, so that Dr. Greville, in his "Algæ Britannicæ," enumerates twelve varieties.

2. G. CARTILAGINEUM (Gristle-like).—"A very doubtful native."

3. GIGARTINA.—*Lamocer*.

Frond cartilaginous, filiform (irregularly divided) purple, or deep red; fructification of two kinds: 1, external tubercles; 2, tetraspores scattered through the surface of the frond."

1. GIGARTINA PISTILLATA (Pistilled).—Growing on rocks near low water mark; very rare; "coast of Cornwall and Jersey." Dr. Landsborough, in his "British Sea Weeds," says, "It is a remarkable plant; the tubercles are large; generally near the point of the branch, which projects like a horn, the colour is a dull purplish or brownish-red; it does not adhere to paper."

2. G. ACICULARIS (Needle-like).—Rather like the preceding, but not so stout; of a dull purple, becoming pink in fresh water; rare in the south of England. I have had specimens from Jaffa.

5. G. TEEDI (Teed's).—"Frond membranaceous, flaccid (horny when dry), flat, linear, repeatedly pinnated with slender, horizontal, distichous, subulate ramuli; capsules globose, on the ramuli."—*Greville*. On rocks; very rare; fronds from two to five inches high.

4. G. MAMILLOSUS (Nippled).—On rocks in the sea near low-water mark; common fronds from three to six inches long, cartilaginous; the capsules on little stalks, scattered all over the frond; colour dark purple. Sometimes used in the same way as the Carrigeen or Irish Moss.

4. CHONDRUS.

Frond cartilaginous, dilating upwards into a flat, nerve-

less, dichotomously-divided frond, of a purplish or livid-red colour.—*Grer.* Named from a word signifying cartilage.

1. *CHONDRES CRISPUS* (Curled).—Very common, and of a very variable form. "Turner figures ten, and Lamouroux thirty-five varieties." "At one time it was much in repute for furnishing gelatine, a light, easily-digested food for invalids; and as the chief supply at first came from Carrigeen, in Ireland, it was called Irish Moss, or *Carrigeen*. The market-price, at one time, was as high as 2s. 6d. per pound; had it continued at that rate, it would have yielded more to the industrious inhabitants of the sea-shore than even a crop of their favourite potatoes. The fashion, however, has gone out, and the price has fallen; but the food prepared from it is as good as ever, and they who have tasted it will need no coaxing to partake of it a second time."—*Rev. Dr. Loundsborough.*

2. *C. NORVEGICUS* (Norwegian).—A rather rare and pretty plant, chiefly found in the south of England and Ireland; fronds from two to three inches high; "colour a deep, rather dull, blood red."

Though so early in the year (February), marine plants have already begun to grow; and I have had a specimen of *Delesseria sanguineum* sent to me with lovely pink fronds, more than an inch long, and also a specimen of the pretty *Ulea lactuca*, of the most bright and delicate shades of green, together with *Porphyra lacusata*, glossy as a satin ribbon, bright and beautiful, and full of promise of what is to come. Like the Turtle and the Swallow, these plants, hidden as they are from our sight by the waves of the ocean, know their appointed time, and once more appear to gladden the eye with their exceeding beauty. How wonderful is the diversity of the works of God, the endless variety, and the provision that is made for every one! How the land plants require fresh water for their support, and the sea plants salt water for theirs; so that what is refreshing to the one, would be death to the other, and the reverse. The more we study the works of God, the more shall we be inclined to declare that His wisdom is infinite, and His power almighty! And surely His loving-kindness is also great, thus to refresh us with so many beautiful objects, and to give us some faint glimpses of Himself in His works. Both the earth and the sea are full of them! S. B.

(To be continued.)

POULTRY-YARD REPORT.

SPANISH P. SHANGHAEES.

I PURPOSE, during the present year, instituting a comparison between the Shanghae and Spanish races. Mine, of the latter, are Minorca, a breed which has received at the hands of the great Spanish breeder merited praise, and from what he says, I presume we may calculate the laying powers of the Minorca as equal to those of their now aristocratic relations.

Subjoined is the report for the month of January.

JANUARY.

Stock SHANGHAEES, 9 pullets of 1853. Of these two laid in December, and then became broody. One laid in January, and is now sitting; one is very ill; only three laying.	Stock MINORCAS, 3 old hens, 4 pullets of 1853. Of these only one of the old hens has laid, and that only during the last few days of the month.
Eggs during the month 36	Eggs during the month 4
lbs. oz. dms.	oz. dms.
Weight of eggs.. 3 13 2	Weight of eggs..... 8 6
Highest weight of single egg .. 0 2 0	Highest weight of single egg 2 3

I calculate the eating powers to be about equal, and I cannot say that I have found the Shanghaees so voracious as some give them credit.

I may state that the house is the same, the partition being of lattice-work; it is warmed by a stove; the Minorcas have the warmer position.—H. B. S., *Monmouthshire.*

NEW BULB.

THE Messrs. Lee, of Hammersmith, sent a most beautiful new half-hardy bulb, in full bloom, to the last meeting of the Horticultural Society, which bulb was "sent out" by Mr. Backhouse, of York, who introduced it from Caffraria. It was labelled, *Imatophyllum sp.*; but Dr. Lindley has named it, provisionally, as *Vallota miniata*. I told Mr. Lee it was a *Vallota* the moment I saw it; but I asked him, particularly, to save me one or two of the seed-pods, as it is only by the seed and pod that most of the plants in this section of Amaryllids can be made out from one another. *Vallota*, itself, is a true *Cyrtanthus*, or the latter is a true *Vallota*, with curved flowers, as I have myself proved by crossing. There is not the least dependence, for generic distinctions, to be placed on the length, shape, size, and directions of the style and filaments, or on the way the filaments are attached to the parts. In some of the *Cyrtanthus*, the filaments, or stamens, are joined nearly their whole length to the inside of the tube. In the old *Vallota* they are only joined one-third of their length, and there is hardly a tube at all to the flower. In this new species the filaments are wholly free, and the six divisions of the flower are free of each other also, throughout their length, which is more curious. The plant, without the flower, would pass for a *Clivia*; and the flowers, without the plant, would suggest *Vallota*.

There is another turn to the question. If the scape is hollow it cannot be a *Clivia*; if it is solid, the plant is not only not a *Vallota*, but does not come into the same section as *Vallota*. I very much doubt if it is a true bulb at all, but only a strong, fleshy-rooted plant, like *Agapanthus* or *Clivia*. Yet I know that Mr. Backhouse sold a dry bulb to Mr. Jackson, near me, which we supposed would turn out to be the same as Mr. Lee's plant; but that bulb is a true *Teltheimia*. All this, however, belongs to the true naming of the plant, and has nothing to do with its value as a most desirable addition to our bulbs.

Here is my home description of it. A strong, fleshy-leaved bulb; the leaves embrace each other at the bottom, and form a column; the largest leaves are fifteen to eighteen inches long, curving out a little from each side of the centre of the column; they are longer, more smooth, and less blunt at the points than those of *Clivia nobilis*, but in that style; and there are six of them on each side, or twelve leaves to the whole plant, and some more coming up in the centre. The flower-scape is from ten to twelve inches high, flattened on two sides. The flower-heads, or umbel, holds twelve flowers, which spread out all round on peduncles, or flower-stalks nearly two inches long; seven flowers were open and five in bud; the opening of the flower is two inches across; the six divisions stand free of each other all the way from the bottom: the three which correspond to a calyx (sepaline segments), are a little shorter and more narrow than the other thin or petaline divisions; the colour is soft orange-scarlet, or vermilion, getting lighter into a lemon-yellow down in the neck of the flower—the stamens are inserted at the very bottom, and are otherwise free, they are not quite so long as the flower; the anthers are attached below the middle, and are full of good pollen: the style or stigma is slightly three-cleft.

As a warning to the owners of this valuable plant, I may remark, that it is very possible the seeds will be ripe long before the pod has turned colour, and if so, they will assuredly sprout before the pod bursts, and they are then as good as lost; if we are right in the name, the pod will burst open near the bottom—not across the top as is more usual. Some of my crosses in *Cyrtanthus*, and the pollen of *Vallota* will come very near to this plant, but the flowers will be almost sessile, as that part may take after the mother. D. BEAUX.

BRAHMA POOTRA FOWLS.

As there has been considerable controversy of late as to the Brahma Pootra fowls which have been imported from America being a genuine breed, I thought it might not be uninteresting for your readers to know that I have just received a very fine Brahma cock *direct* from China; a pair were taken on board the vessel, but unfortunately the hen died on the voyage. The bird I have received is a noble fellow, with a beautiful arched neck, and a bold round chest, compact body, and very broad behind, tail short, and slightly inclined, well-feathered, short yellow legs. His head is very perfect, he has a good, upright single comb, with short yellow beak, and a good sized regular wattle. The colour of the bird is much darker than the American Brahmas; his neck and back hackle are of a lightish grey pencilled with black, the whole of the body, with the exception of wings and tail, is a light grey barred with black, each bar shaded with green; wings black and grey shaded with green; tail black, and shaded in a similar manner.

I am partly induced to trouble you with this, by way of proving to the author of "The Poultry Pentalogue" that all Brahmas are not manufactured in America. I am not surprised that that gentleman should express such an opinion, when I know, that by reason of the scarcity of these birds in this country, that they have been crossed with all colours of Shanghaes. How frequently have we seen of late a pen of Brahmas, at an Exhibition of Poultry, having almost as many buff feathers in their plumage as a pure-bred buff Shanghae, and some very much like a Partridge. Such birds are, undoubtedly, the result of a cross with Shanghae fowls, and are not by any means entitled to be called Brahma Pootras. Last summer, I crossed a Brahma Pootra cock with a buff Shanghae, the result was, that the young birds plumage turned out a mixture of brown, grey, and black, and not one of them came like the old Brahmas. By breeding in the right strain, in every instance the young birds came exactly like their parents to a feather; this is a good proof of the breed being genuine. I consider the pure bred Brahmas to be decidedly the most handsome fowls that have been imported.—J. S. BRAND.

P.S. A friend of mine, who has been trading between Shanghae and Hong Kong for the last ten years, assures me that he has taken a great many Brahma Pootras from the former to the latter place.

[The controversy respecting "*Brahma Pootras*" or "*Grey Shanghaes*," we apprehend, stands thus, "Are any specimens of the birds thus designated a distinct original breed?" Now, the mere fact of importation, on which so much stress is often laid, of itself proves nothing with regard to this proposition, but leaves it still an open question as to whether these are only a variety of the Shanghaes, or the result of a cross, either of which conditions may be perfectly compatible with their importation. The P.S. to Mr. Brand's communication would even strengthen the former supposition, since Shanghae is there referred to as one of their habitats, a locality, be it remembered, far away from the districts watered by the river Brahmapootra, whence the distinctive name has been assumed. What we require as proof of the distinctness of any breed of fowls, would comprise permanent points of distinction in form, habits, or character, for colour alone, granting that that feature could be here established, would only place them in the Shanghae list, and the former position, we imagine, has not as yet been made out for them.—W.]

"ON A NEW METHOD OF PROPAGATING PLANTS."

BY E. J. LOWE, ESQ., F.R.A.S., F.G.S. & C.

"THE author states that the experiment of a new method of propagating plants has been so successful, that he has taken the liberty of forwarding to the Royal Society this short paper upon the subject, for the guidance of those who are interested in the advance of horticulture.

"It had occurred to him, that if a cutting of a plant were sealed at the base, so as to exclude the moisture of the soil

from ascending the stem in injurious quantities, the method of striking cuttings of most species of plants would not be so precarious a process as at present; and accordingly some collodion was obtained in order to make the experiment.

"With respect to this new process, he states, that immediately upon the cutting being severed from the parent stem, the collodion was applied to the wound, and then left a few seconds to dry, after which the cuttings were potted in the ordinary manner.

"To test the value of this new process mere effectually, duplicates of all the species experimented upon were at the same time similarly planted, without the collodion being applied to them.

"Experiments were carried on in two different ways; one batch of cuttings being placed on a hotbed, whilst a second batch was planted in the open ground, without even the protection of glass.

"*First Batch.*—All of which were placed on a hotbed on the 1st of September, and examined on the 1st of October:—

Stove Plants.

Number of cuttings with collodion applied.	Name of Plant.	Number of cuttings which took root.	Number of cuttings without the application of collodion.	Number of cuttings which took root.
1	<i>Ixera coccinea</i>	1	1	0
1	<i>Tacsonia manicata</i> ..	1	1	1
3	<i>Franciscea Hepeana</i> ..	3	3	0
3	<i>Franciscea Pohliana</i> ..	3	3	0
2	<i>Gloxinia Maria van Houtte</i>	0	2	1
2	<i>Begonia incarnata</i> ..	2	2	1
8	<i>Achimenes patens</i> ..	7	8	6
2	<i>Hoya bella</i>	2	2	1
2	<i>Rondeletiaspeciosa</i> ..	2	2	1
2	<i>Allamanda nerifolia</i> ..	2	2	1

Greenhouse Plants.

6	<i>Boronia serrulata</i> ..	5	6	0
3	<i>Polygala dalmaisiana</i>	1	3	0
6	<i>Polygala grandiflora</i> ..	3	6	2
6	<i>Verbena luna</i>	6	6	6
1	<i>Chorezema cordata</i> ..	1	1	0
1	<i>Epacris pallida</i>	0	1	0
2	<i>Leschenaultia formosa</i>	2	2	1
1	<i>Swainsonia astragalifolia</i>	1	1	0
1	<i>Swainsonia galegifolia</i>	0	1	0
2	<i>Abelia rupestris</i>	2	2	0
4	<i>Plectranthus color, picta</i>	2	4	2

"*Second Batch.*—Planted in the open ground on the 1st of September, and examined on the 1st of October:—

Hardy Plants.

Number of cuttings with collodion applied.	Name of Plant.	Number of cuttings which took root.	Number of cuttings without the application of collodion.	Number of cuttings which took root.
12	<i>Garrya elliptica</i>	5	12	1
12	<i>Erica vagans</i>	7	12	4
18	<i>Bupleurum longifolium</i>	6	18	0
12	<i>Laurus fatens</i>	10	12	7
6	<i>Rose, Souvenir de la Malmaison</i>	4	6	3
12	<i>Taxus baccata, golden leaved var.</i>	8	12	4

	Total number of cuttings to which collodion was applied.	Number of cuttings which took root.	Total number of cuttings without the application of collodion.	Number of cuttings which took root.
First batch	59	46	59	23
Second batch	72	40	72	19

"The experiment, the author considers, speaks for itself. Notwithstanding the season being too far advanced for the full benefit of the process to be thoroughly observed, still twice as many cuttings took root treated by the new method as had rooted by the old. The mortality in the open ground was increased by slugs having eaten off above the soil some of the cuttings; those thus damaged were examined after they had been in the ground a month, and it was found that the collodion was quite as sound as when first applied. It would therefore appear that the collodion seals the wound of the cutting, and protects it from the fatal effects of damp, until roots are prepared to force through the covering of gun-cotton. It is further stated, that the application of this solution has been found to be exceedingly beneficial in the pruning of such plants as *Euphorbia speciosa*, *Impatiens latifolia*, *Impatiens latifolia-alba*, *Hoya bella*, *Hoya imperialis*, &c., the cut branches being prevented from bleeding.

"It is the author's intention next spring to follow out this experiment, in budding and grafting, as he considers that it will also be useful in this branch of horticulture.

"Gutta-percha, dissolved in ether, was in some instances substituted to heal the wounds caused by pruning; yet owing to this solution not drying as rapidly as collodion, the first, and sometimes the second application was not sufficient.

"The effect of these solutions upon cut flowers was very marked. Two branches were gathered as nearly alike as possible; to the flower-stalks of the one, collodion was applied. These flowers were placed in vases filled with water; those coated over with collodion began to fade in thirty-six hours, and many were quite dead in three days; whilst the flowers merely placed in water in the ordinary manner remained fresh and healthy. Those that faded soonest were *Reseda odorata* and *Tropaeolum majus*, and those which were least affected were *Tugetes erecta* and *Senecio crubescens*."

"ON THE ACIDITY, SWEETNESS, AND STRENGTH OF WINE, BEER, AND SPIRITS."

BY H. BENICE JONES, M.D., F.R.S.

(1) "THE acidity of the different liquids was determined by means of a standard solution of caustic soda. The quantity of liquid neutralized was always equal in bulk to 1000 grs. of water at 60° F.

"The acidity in different—

Sheries varied from 1.95 grs. to 2.85 grs. of caustic soda.			
Madeira	"	2.70	" 3.60
Port	"	2.10	" 2.55
Claret	"	2.55	" 3.45
Burgundy	"	2.55	" 4.05
Champagne	"	2.40	" 3.15
Rhine wine	"	3.15	" 3.60
Moselle	"	2.85	" 4.50
Brandy	"	0.15	" 0.60
Rum	"	0.15	" 0.30
Geneva	"	0.07	"
Whisky	"	0.07	"
Bitter Ale	"	0.90	" 1.65
Porter	"	1.80	" 2.10
Stout	"	1.35	" 2.25
Cider	"	1.85	" 3.90

"Hence the order in which these wines may be arranged, beginning with the least acid, is Sherry, Port, Champagne, Claret, Madeira, Burgundy, Rhine, Moselle.

"(2.) The sugar was determined by means of Soleil's sac-

charometer, which at least gives the lowest limit to the amount of sugar.

"The sweetness in different—

Sheries varied from 4 grs. to 18 grs. in the ounce.			
Madeira	"	6	" 20
Champagne	"	6	" 28
Port	"	16	" 31
Mahnsy	"	56	" 66
Tokay	"	71	"
Samos	"	88	"
Paxarette	"	94	"

"Claret, Burgundy, Rhine, and Moselle contained no sugar.

"Hence the order in which these wines may be arranged, beginning with the driest, is—

Claret	Champagne
Burgundy	Port
Rhine	Mahnsy
Moselle	Tokay
Sherry	Samos
Madeira	Paxarette.

"In a dietetic view, assuming that the sugar becomes acid then the mean results as to the acidity of the different fluids examined, beginning with the least acid, is—

Geneva	Champagne
Whisky	Cider
Rum	Port
Brandy	Porter
Claret	Stout
Burgundy	Mahnsy
Rhine wine	Madeira
Moselle	Ale
Sherry	Tokay
Madeira	

"(3.) The alcohol was determined by means of the alcoholometer of M. Geisler of Bonn

"The strength of different samples of—

Port varied from 20.7 per cent. to 23.2 per cent. by measure.			
Sherry	"	15.4	" 24.7
Madeira	"	19.0	" 19.7
Marsala	"	19.9	" 21.4
Claret	"	9.1	" 11.1
Burgundy	"	10.1	" 13.2
Rhine wine	"	9.5	" 13.0
Moselle	"	8.7	" 9.4
Champagne	"	14.1	" 14.8
Brandy	"	50.4	" 53.8
Rum	"	72.0	" 77.1
Geneva	"	49.4	"
Whisky	"	59.3	"
Cider	"	5.4	" 7.5
Bitter ale	"	6.6	" 12.3
Porter	"	6.5	" 7.0
Stout	"	6.5	" 7.9

"The Burgundy and Claret have less alcohol than was found by Mr. Brande forty years ago in the wines he examined. The Sherry is now stronger, the Port is not so strong, the Marsala is weaker, the Rhine wine is the same strength, the Brandy is as strong as formerly; the Rum is nearly half as strong again; the Porter is stronger, and the Stout rather stronger than formerly.

"Lastly, the specific gravity of each liquid was taken. As this however chiefly depends on the amount of alcohol and sugar present, and as these were directly determined, the specific gravity may be taken as a distant control on the amount of sugar present.

"Thus, in those wines in which the amount of alcohol was the same, the specific gravity was found to vary with the amount of sugar found by the saccharometer."

[Proceedings of Royal Society, VI. No. 101.]

RICE MEAL AS PIG FOOD.—COST OF POULTRY FEEDING.

ONE of your Correspondents, who signs himself T. L., asks for information respecting rice meal as food for pigs. At the

latter end of last year I purchased some rice in the grain (slightly damaged), and which, with the addition of a little Indian meal all boiled together, I fed a pig for home use, and I must say I never saw one thrive better; for in about seven weeks he increased in weight from about 160 lbs. to 285 lbs. With regard to the quality of the bacon, I must state, that I do not think it equal to some which I had previously from pigs fed upon oatmeal. It is, however, sweet, and of good colour, but rather overdone with fat.

You have occasionally requested Correspondents to furnish information respecting the keep, &c., of Poultry; and as I have taken some pains to ascertain the cost of mine, I must state, that I think young poultry, especially cockerels, eat more than full-grown birds; whilst of the latter, laying hens eat considerably more than either cocks or hens which are not at the time producing eggs.

I have, at present, twenty-one hens and pullets (Shanghaes) with the exception of two black Spanish and two Shanghae cockerels, and their consumption weekly is as nearly as possible—

	s. d.
8lbs. of Barley Meal, at 1½d. per lb.	0 10
4lbs. of Bran, at ½d. per lb.	0 2
17lbs. of Grain*, at 1d. per lb.	1 5
	—
	2 5

Averaged, 1½d. per week each.

They have, also, the peelings of Potatoes boiled and mixed with the meal. They are kept in a yard about fourteen yards by eight, and have also the run of a grass plot. They are in good condition (in fact, I lost two hens a couple of months ago from over-feeding, and was obliged to lessen the amount of food given them), and I have had from forty to fifty eggs weekly since the beginning of the year, although some of my pullets have not yet commenced laying. I quite agree with the remarks you made a short time ago, as to the superiority of Shanghaes, on the whole, over our other kinds of fowls.

I last year had Game, Dorking, Black Spanish, and Shanghaes. The two former I have given up, as the Game I found to be poor layers, and there was no keeping the Dorking within moderate bounds. My Black Spanish lay large eggs, and about five in a week each, but for about two months during moulting time I had not a single egg from them, whilst some of my Shanghaes were laying when they were almost destitute of feathers.—T. S.

* Consisting of Indian Corn, Barley, Oats, and Wheat sweepings.

TO CORRESPONDENTS.

. We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of The Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

THE PIP IN POULTRY (H. M.).—As I have stated elsewhere, there is no such disease as Pip in fowls; the dry scaly tongue is always caused by febrile disturbance, arising from over-feeding, stimulating food, or some other cause. It constantly occurs in any inflammatory disease of the respiratory organs, as the irritation caused by the worms in gapes, in catarrh, roup, &c.; it should always be regarded as a symptom, never as the disease itself; the dry tongue occurring in human patients is precisely similar. If the scale of membrane is loose, it should be removed, and a little borax may be dissolved and poured into the mouth. Should there be no evident cause, a dose of alterative medicine may be given, as a teaspoonful of castor oil, or one grain of grey powder.—W. B. ZEIGEMEIER, Willemsden.

PIG-FATTING (T. L.).—The best mode of fattening pigs is to combine roots, meal, and any milk slops attainable. We think the value of the roots, comparatively, stand thus:—1st, Parsnips; 2nd, Mangold; 3rd, Swedes; 4th, Carrots. The comparative value of the meals, thus:—1st, Barley; 2nd, Oats; 3rd, Indian Corn; in addition, the various dressings from Wheat, such as Pollard, &c. Some use damaged Rice. As a general principle, it is well to mix these things. The roots hoiled, mixed up with meal, and given warm. Feed three times a day, give as much as they can eat.

INDIAN GAME FOWL (J. T., Cirencester).—The Indian Game Fowl is a bird of greater weight and more compact figure than our English breed, but inferior in symmetry and carriage. They vary in respect of colour. The Golden Spangled Hamburg Cocker must have a full but firm rose comb, tapering back to a point, which is slightly curved upwards.—W.

WEEDING THORNS (Excelsior).—You can obtain them of any nurseryman who advertises in our columns. *Filberts* the same, and you may plant them now, if they are moved carefully, but this should have been

done in November. If you refer to previous volumes you will find several essays on their culture. It is quite impossible to give such essays in answers to questions.

CUTTINGS (Easton Court).—You will have seen that we have adopted your suggestion. We are always obliged by any hints.

CUCUMBERS (W. W.).—The bed on the flue will be a failure; it will bake the soil, and scald the roots of the plants.

HERACLEUM GIGANTEUM (W. E.).—Messrs. Hardy and Son, Florists, Maldon, Essex, always keep a stock of this plant; but we should think you might obtain it of any extensive florist.

HAMILTON'S CATALOGUE (Effie).—You will be as sure of getting good Balsam Seed from Mr. Hamilton, Margaret Street, as you would from any other equally respectable seedsman. As far as we have noticed, his arrangement of the *Roses*, both as to colours and classes, is quite correct, and the selection very good.

A HILL AND ITS BASE (A Reader).—The bill is of this shape—

and you ask, if "this bill of one acre in surface will grow more than if the land under it in a horizontal line were sown? The soil in both cases being equally fertile." Of trees, or corn, which can only grow perpendicularly, the horizontal line forming the base of the hill would grow as much as the semi-circular outline; but of grass, or other plants that creep over the surface, the semi-circular would bear the largest quantity.

INTRODUCTION TO BOTANY (W. Johnston).—We prefer Hensley's *Rudiments of Botany* to any other to begin with. It is very cheap.

SWELL-LESS EGGS (Penelope).—Do not feed your hen so stimulatingly. Leave off the meat entirely; mix bran with the ground corn, half-and-half, and give her, at intervals of two days, three pills, each pill containing one grain of calomel, and one-twelfth of a grain of tartar emetic. Give her Cabbage-leaves, and any other green food you can obtain.

WILLIAM ADAMS (C.).—The ten shillings has been gratefully received.

RIE-MEAL FOR POULTRY (A Regular Subscriber).—It is very good given alternately with corn or other more stimulating food. We should mix it half-and-half with barley-meal. We know of no mode whereby broody hens can be prevented going into nests where they are not welcome, except the effective mode of shutting them up in a place by themselves.

GOLDEN-PENCILLED HAMBURGH EGGS (W. Dyer).—Some such as you require have recently been advertised in our columns.

GOVERN (G. P. H.).—This shedding its fruit, is either grown in an unsuitable soil, or is a tender variety, and is not grown in sufficient heat. We cannot say more without further particulars.

WHITE ON COCHIN COCK'S COMB (A Constant Reader).—This is called "the White Comb." It is easily removed by rubbing it with an ointment of cocoa-nut oil, with a little turmeric powder added. If you cannot get cocoa-nut oil, use citrine ointment, rendered very soft by adding a little sweet oil, and then mixing a little turmeric powder. Two or three applications will effect a cure.

AUTUMN BROCCOLI (E. Faax).—Sow *Early Purple Cape*, *Walcheren*, and *Green Cape*, the first week in April. The plants will not require a hotbed. Sow on a warm border, and keep them well watered.

PEARS (Omicron).—Both the *Jersey Gladioli* and the *Jean de Witte* will do well in the situation you refer to. *Van Mon's Leon le Clerc* is a Pear in use during November and December.—H.

ANDROSACE LANUGINOSA (M. C., Dublin).—It is very pretty; a native of the Himalaya; grow it in a pot; soil, peat and sandy loam; water it carefully; and keep it in a cold frame during the winter. For a *Pencilled Hamburg Cocker*, apply for particulars to some of the advertisers in our columns. List of *Verbenas* next week. *Silver Pencilled Hamburgs* and *Bolton Greys* are the same race of Poultry.

SPARROWS (S. S. S.).—Traps and a gun are your best remedies.

GRAPES (Snowdrop).—We should prefer the *Barbarossa* to the *Charlesworth Tokay* for your late viney. They are both excellent grapes. Your "flowering Gooseberry" is one of the ornamental *Ribes*, but, unless we saw a cutting of it we could not tell its specific name.

SWOLLEN FACE OF A FOWL.—"B. H. E. has in her possession a black Spanish hen, which has not laid for some time; she has an enormous swelling on one side of her face, and the eye on that side has been watering, and is still partially closed; otherwise she appears perfectly well, is lively, and eats and drinks as usual. Her face has been frequently fomented with warm milk and water, and warm camomile-tea. She has been given one Plummer's pills, and pills of Cayenne pepper, ginger, barley-meal and flour, and plenty of warm, nourishing food; the swelling has been twice opened, without improvement."—The swelling, in this case, probably arises from an accumulation of solid secretion in the cavity of the nose on the affected side. I have seen it occur in Spanish fowls more than once. If this view of the case is correct, the only remedy is a free opening below the eye, and the extraction of the secretion; but to accomplish this successfully requires some knowledge of the anatomy of the parts.—W. B. ZEIGEMEIER.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 51.2° and 34.6° respectively. The greatest heat, 69°, occurred on the 19th in 1836; and the lowest cold, 16°, on the 17th in 1845. During the period 126 days were fine, and on 63 rain fell.

BRITISH WILD FLOWERS.

(Continued from page 433.)

CARDAMINE IMPATIENS: Impatient, or Irritable Lady's Smoek; Noli-me-tangere; Quick or Impatient Cress.

Description.—It is an annual. Root small, tapering. Herb

erect, slender, pale green, smooth in every part, except the *stipulas*. Stem one-and-a-half or two feet high, generally a little branched, leafy, angular, hollow, often zig-zag. Leaves of numerous opposite lance-headed leaflets, with an odd one; all equal, more or less notched, rarely entire; pale beneath. *Stipulas* lance-headed, acute, bent down, clasping the stem, all finely fringed, and evidently *stipulas*. Flowers numerous, in erect spikes, extremely small. Petals white, but very transitory, and occasionally not present. Pods erect, very slender, composing long clusters, and discharging their seeds with a crackling noise, and great force, on the slightest touch or concussion, by means of the valves rolling back suddenly. The whole plant is disagreeably bitterish and pungent.

Time of flowering.—May to June.

Places where found.—Mountain pastures by the sides of rivulets, on moist, rocky, or stony places, in the north of England.

History.—Johnson, in his edition of *Gerarde's Herbal*, speaks of this species under the title of *Sium minus impatiens*, and says that it was "kept in divers of our London gardeners, and was first brought hither by that great treasurer of nature's rarities, Mr. John Tradescant. The nature of this plant is such that if you touch but the pods when the seed is ripe, though you do it never so gently, yet will the seed fly all abroad with violence, as disdaining to be touched, whence they usually called it *Noli-me-tangere*, as they, for the like quality, name the *Persicaria siliquosa*." Soon after Johnson wrote it was discovered to be a native of England, for Parkinson says it was found "in our own land." Ray, but a few years later, says it is to be observed "among the stones under the sears near Wherf, a village some three miles distant from Settle, in Yorkshire." He also states, in his "Historia Plantarum," that he found it near Halsted, in the spring of 1685, in a ditch by the road leading to London.—(Smith. *Withering*. Martyn. Ray. Johnson's *Gerarde*.)

The prize-list list for the sixth great Annual Poultry Contest at Birmingham announces Tuesday, the 12th of December, and the three following days, as appointed for that Exhibition.

The Committee of Management, we doubt not, have given the fullest consideration to the expressed wishes of those numerous exhibitors who desired some curtailment in the protracted period of their fowls' confinement in Bingley Hall; and if that body now find themselves unable to grant all that has been asked, the enormous expences attending an exhibition of this magnitude must be accepted as their sole motive in declining to comply with the suggestion. We are not, however, without hope that it may be found compatible with their arrangements to close at an earlier hour on the Friday, so that the birds farthest from home may be sent off on that evening. This would, undoubtedly,

be a great boon, many pens having often previously suffered from the intervention of Sunday, and the more limited means of railway transit on that day. Additional confidence may also be felt by exhibitors from the care bestowed on the birds at the last Birmingham meeting, with regard to the feeding, and management generally. The supervision of the former department having been confided to Mr. E. Hewitt, his well-known experience and constant attention prevented the usual proportion of invalids, and very few, if, indeed, any birds, that arrived in health, left the worse for their abode under his charge. At the same time, there are many instances before us of "four days exhibitions," where these essential precautions were sadly neglected; and there are, moreover, few, if indeed any, cases where an equally liberal expenditure with that of Bingley Hall calls for the same indulgence.

The general arrangement of the classes varies from that of previous years, the *Hamburgs* now commencing the list. Convenience in assigning the birds to the situation best suited to the different classes has probably induced this alteration, since there is no appearance of an alphabetical, or other systematic classification.

The prizes for "the best cock and one pullet," formerly allotted to Dorkings and Spanish, are now withdrawn. But we are glad to notice a fourth class "*for any other variety of the Polish fowl*," thus doing away with the inconsistency of compelling the entries of birds of undoubted Polish blood among the miscellaneous fowls.

Spanish come next; then *Dorkings*, coloured and white; after these, *Shanghaes* or *Cochin-China*, in their four varieties; and these are again followed by *Brahma Pootra* fowls; so here the oft-disputed, and still far from settled, question of the distinctness of breed in these birds from the *Shanghae* appears to be sanctioned. We do not, however, think that fault should be found with this resolution of the Birmingham committee, though, in our opinion, a class as *Grey Shanghaes* would have better suited them, at any rate until an enumeration of proved specific distinctions had taken the place of mere vague assertion.

Game fowls are as before, as also *Malays*, and the class for *any other distinct breed*, and *Bantams*. In respect of the latter, we would have suggested, for the guidance of exhibitors, some notification with respect to the admissibility of "*booted and tufted*" specimens, to the White and Black classes, a recent decision at an important meeting rendering this desirable. *Geese* still stand as a single class, though we think they might have been divided as "*Emden*," "*Toulouse*," and "*Pied*." *Turkeys* have premiums for both old and young birds. *Ducks* have undergone no change, but *Guinea Fowls* are passed over unnoticed.

Pigeons are admirably arranged, the fancier of these birds having every inducement to exhibit without the complicated sub-divisions that oftentimes confuse this class.

The amount of the several prizes has been increased throughout—first prizes for fowls standing uniformly at £3; second at £2; and the third at £1. But might not those of the more important breeds, such as Spanish, comprised in a single variety, and Dorkings in two only, have had some increase above the *Hamburgs* and Polish, to each of which, in their four varieties, no less a sum than £48 is assigned, while Dorkings have only half this, and Spanish but one quarter: even less than Bantams? No one could have fairly objected, if in the instance of Polish and *Hamburgs* the prizes had been reduced a pound, and the saving carried to increase the premiums of such birds as claim greater encouragement on account of their higher character, as not merely ornamental, but likewise economical poultry.

The Pigeon prizes are increased from 10s. and 5s. respectively, to 15s. and 10s.

We will now proceed to notice the points in which the regulations have been altered from those of last

year. And here we find that cottagers will now compete separately, and gratuitously, with the promise of "*liberal premiums to deserving specimens*." This is assuredly well done, for it cannot be doubted, from the peculiar character of this great exhibition, such persons had the odds greatly against success under the former principle of common competition.

The clauses of two months *bona fide* ownership, of the selling price to be affixed, are both retained, but the following is a wise addition, not merely saving time to the officials, but checking any tendency to act upon information obtained after the entries are closed. "*No alteration whatever can be made in the certificates after they are received by the Secretary*."

The rate of subscription is raised to £1 for exhibitors; but the number of their pens is now limited to four, of which there may not be more than two in the same class; but "*exhibitors of Pigeons 'only'*" may enter six pens, but of these not more than two to be of the same variety. The rules by which the restrictions of the number of pens has hitherto been enforced has been so constantly evaded by the entrance of birds in the names of persons having no real *bona fide* ownership in them, that we shall be curious to observe how such infractions of the regulations will be guarded against now that the limitation has become still more stringent. A fine of three shillings will follow the omission of not sending birds that have been duly entered; had this been of even larger amount, such a penalty could not be objected to, on account of the great inconvenience that carelessness in this respect entails upon those who are entrusted with the management.

A strict rule also provides for the exclusion of all persons from Bingley Hall before the opening of the Exhibition on the Tuesday morning, those only being excepted who may be actually engaged on official business within the building.

The points have now been mentioned on which the classification of the birds, the amount of premiums, and the regulations of the present year, have undergone an alteration from those of 1853. The notification, however, that "seven silver vases, of the value of six guineas each, will be awarded, instead of money prizes, for the best pen of Pencilled *Hamburg*, Spangled *Hamburg*, Polish, Spanish, Dorking, *Cochin-China*, and *Game fowls*," betokens a degree of liberality on the part of the committee that will be generally appreciated. The competition for these vases will be open to both the adult and the chicken classes in each of the above breeds.

Had space been at command for a class of single cock birds of the different families of any age, one great object of Poultry Societies, the attainment of stud birds of the highest excellence, would have been still more readily attained; but, while saying this, we are not forgetful of the reasons that probably forbade its institution, for every inch of even the extensive area of Bingley Hall has, doubtless, many claimants for its occupation.

Though in some few particulars now alluded to possible improvements in this prize-list have occurred to us, we most gladly recognise its general excellence, and the obligations of the poultry-keeping community to these gentlemen who have carried the Birmingham Society through the many difficulties of its earlier years to its present unexampled prosperity and influence.

NEXT in our list of PEAS comes

FAIRBEARD'S SURPRISE.

Synonymes.—*Surprise, Early Surprise.*

This variety, and the *Champion of England*, were raised from two peas found in the same pod; the former being round, and the latter wrinkled. They were selected by Mr. William Fairbeard, of Green-street, near Sittingbourne, from a crop of *Dwarf White Knight's Marrows*, a plant of which having exhibited a more than usual early character.

The *Surprise* is a very excellent early Marrow Pea, somewhat earlier than *Champion of England*, but not more so than a day or two, at most. The plant is of a free but not robust habit of growth, and always with a simple stem, which is about five feet high. The pods are produced at every joint, beginning at about three feet from the ground, and number from eight to ten on each plant. They are generally single, but sometimes in pairs from three-and-a-quarter to three-and-a-half inches long, and three-quarters-of-an-inch broad, slightly curved, but not quite so much so as *Champion of England*, and *Champion of Paris*. They contain from seven to eight peas in each, which are of a good size, but not so sweet as those of *Champion of England*. The ripe seed is some-

what oval, and of a pale olive-green colour. The seed was sown on the 5th of April, and the plants bloomed on the 15th of June. On the 21st the blooms dropped, and the slats appeared, and on the 9th of July the pods were quite filled. At first the pods are so flat as to give the idea that the peas are not sufficiently grown, but notwithstanding this appearance they are quite fit to be gathered.

Though an excellent Pea the *Surprise* is one which may easily be dispensed with. If there was no *Champion of England*, then we might retain the *Surprise*; but I give the preference to the former.

FAIRBEARD'S CHAMPION OF ENGLAND.

When I first saw the *Champion of England* Pea, the

whole stock consisted of a few rows in the nursery ground of Mr. Fairbeard. It was on the second day of June, about eleven years ago, and I well remember the interest with which I viewed a wrinkled Marrow Pea ready to gather so early in the season. As I have stated already, this and the *Surprise* both came from the same pod, the produce of a plant found in a crop of the *Dwarf White Knight's Marrows*. The best indication of the superiority of this variety is the rapid progress of its popularity, and the universality of its cultivation. It belongs to the class called "*Knight's*" or *Wrinkled Marrows*, and is, without doubt, one of the most valuable acquisitions which have been obtained for many years.

The plant is of a strong and luxuriant habit of growth, with a stem from six to seven feet high, which is often simple, but also very frequently branching; the laterals are produced within about eighteen inches of the ground, and sometimes assume as vigorous a growth, and attain as great a height as the main stem. They produce pods at the first joint above the lateral, and are

continued at every succeeding joint to the greatest extremity of the plant, amounting in all to from twelve to nineteen pods. The pods are generally single, but very frequently in pairs, from three-inches-and-a-quarter to three-inches-and-three-quarters long, three-quarters-of-an-inch broad, slightly curved, and terminated abruptly at the point. When they begin to fill they are rather flat, but soon become more narrow and round; the surface is quite smooth, and the colour light green, till they begin to ripen off, and then they become paler and shrivelled. They contain from seven to nine very large peas, which are very closely packed and compressed, over half-an-inch long, nine-twentieths broad, and seven-twentieths thick. The ripe seed is wrinkled, [and of a pale olive-green colour. The seed was sown on the 5th of April, and the plants were in bloom on the 14th of June. On the 20th the blooms began to fall, and on the 10th of July the crop was fit to be gathered. It is very prolific.

R. H.

(To be continued.)

SEASONABLE NOTES.

LET me again remind our readers of the importance of *retarding the blossoms of Fruit-trees*. I am quite aware that it is too late to talk of this as to some kinds, but not as to all. The fact is, such a host of important matters press at this season on the mind of those who undertake to teach the unknowing in gardening matters, that they are puzzled to know what to select. Our

readers, however, need never be at a loss, for a reference to back volumes will soon set them right, be the case what it may. The basis of this retardation principle, which I was the earliest to get recognised by some of our first-rate men, stands thus:—every week we advance into the Spring as to the unfolding of the blossoms, the air becomes progressively milder, and any recurrence to frost of necessity assumes a moderated or qualified character, through the warmth of the soil, walls, or, indeed, any contiguous body. I urge this as certain on general principles; it is of no use telling me of exceptions. Many people allow themselves so to be terrified by these that they never carry out anything by system, but squander away their time in indecision. Verily, the world at large must appear a chaos to such characters.

The foregoing is not all as to the setting of the blossoms; the ground warmth at the roots is a most important consideration. I hope, that by this time most of our readers recognise the propriety of endeavouring to culist the action of the root whilst the development of the foliage is taking place; and are aware that all our best foreign gardeners instantly aim at this as the fundamental principle in forcing. Indeed, common sense alone will point to the propriety of sustaining, as far as possible, a reciprocal action between root and branch; and it must be remembered, as to our fruit-trees from warmer climes, that in all probability the soil in many of those climates never becomes so low, in relation to atmospheric warmth, as in Britain; in the ordinary phraseology of gardeners,—those climates possess more “bottom heat.”

Such being admitted, it will also be readily conceded, that if by any kind of handy-work we can arrest the development of the blossoms and foliage, whilst the soil where the roots are situated is advancing several degrees in temperature, through the steadily advancing character of spring temperature, we are gaining the point most favourable both to a hearty and unchecked development of the foliage, as well as increasing the chances for a crop of fruit.

I will now take it for granted that these doctrines are sufficiently sound to recommend themselves to our readers; and I may just point to a practical application of the principle, or, at least, show forth my own practice in this respect. It is very simple where canvass can be applied; it consists merely in reversing the protective principles, *viz.*, in warding off all sudden excitement through sunshine during the day, and in exposing the trees to the night air, to cold winds, &c. One caution alone is necessary here—when the trees actually begin to unfold their buds the retardation principle must gradually merge into the protecting principle, and this will consist in avoiding severe night frosts and cutting winds. Where, however, people are obliged to use fir, or other boughs, for protection or retardation, the case differs considerably. Here they are not capable of adaptation to emergencies, but once stuck in they must remain for weal or woe; any attempt to cover and uncover through these things would seriously affect the latter question, which, indeed, is likely to become the most serious question of the day.

Next, let me remind our readers of the propriety of looking sharp after the eggs of that pest of the Apricot, the *Red-bar Moth*. I may again state that the eggs adhere to the principal branches as though pasted on, and are of an oval character, like a large parsnip seed dotted over. These will begin to hatch by the time the foliage is unfolded, and their ravages soon become manifest, for each little rogue of a caterpillar selects a group of leaves connected with the spurs of the future year, and making up his mind to have comfortable quarters for many weeks, he rolls them instinctively round his person, and thus provided with a canopy which bids defiance to rains, &c., he sallies forth at the command

of his voracious appetite on marauding expeditions. In no case is the old adage, “a stitch in time,” better verified than in the destruction of these eggs; it needs but a sharp eye and a good thumb nail, and they are annihilated; the gelatinous issue from their ruins will pretty obviously attest to the amount of vitality in this apparent patch of dry paste.

Come we next, in this wandering paper, to the *Peach-trees*, now, of course, pruned and trained, and I hope my presumption may be pardoned if I turn catechist for a moment. Have you dressed your wall or your trees, I would ask? Again let me repeat that such a course is indispensable. The best time, as I think, to perform this, is the moment the trees are nailed or trained; and I find it the simplest and most certain course to apply the mixture with a half-sized painter’s “dusting brush.” The following is my favourite mixture, but, doubtless, other practical gardeners have recipes, differing, of course, it may be, but, perhaps, as efficient: this is, to repeat the matter,—soft soap, four ounces to a gallon; sulphur, six handfuls; and as much thick clay water as will make the whole into a regular paint; this applied between every two branches, in fact, to every naked portion of the wall. With this application the red spider has never proved of any particular moment to me, although I have occasionally been honoured with visits from him. I prefer this before any other doctoring, for, indeed, as the summer advances, we generally find enough to do in disbudding, stopping, and the other minutiae, which ought to be had recourse to.

I may here advert to a novel mode of *protecting bush-fruit* from the attacks of birds. It is well-known by Gooseberry-growers that the Finch family, Tomits, and others, are particularly partial to the buds of Gooseberries, Cherries, &c., when in the act of germination, or in what, perhaps, may be termed a *malting* condition. So great are their ravages at times, that I have known most of the bushes in a given garden three-parts destroyed by them,—for it is not only the loss of the season’s crop that we have to lament, this severe disbudding process breaks-up the very constitution of the tree; and all that is needed to complete its utter destruction is a visitation from the caterpillars and red spider subsequently. Some people hang strings or threads over their bushes; some suspend fragments of glass, in pairs, to tinkle with every puff of wind, like an Æolian harp; others run the string through potatoes at given distances, and stick feathers in the potatoes to represent hobgoblin birds, &c. It is pretty-well known that they do not care a fig for either after the novelty has passed, which is in about three days, for they may be seen to alight on the very strings; and as for the music, I am not sure but it soon proves attractive.

After a very hard winter these birds are most voracious, I suppose, in consequence of the great destruction which ensues amongst other kinds of food to which they are attached; and the Gooseberry-grower may always look sharp out in the beginning of February.

It has often occurred to me that much might be done in preventing the *ravages of insects, birds, &c.*, by using some application that would render the taste of the object to be protected nauseous to the marauder’s palate; and that such, if in a fluid state, might be most economically applied—as to labour—by the syringe. With this view, as soon as I found war was declared by the birds against the Gooseberry buds, I cleared out a reservoir holding nearly an hundred gallons, and commenced brewing, although neither March nor October. The materials and proportions were about as follows:—Soft soap, two ounces to a gallon of warm water, well beat; two quarts of soot, added to the above, with three handfuls of flower of sulphur, and as much clay mud, well strained, as would make the whole into

as thick a mixture as could be delivered by the syringe without clogging it. The whole being kept stirred, one man took a couple of pots full, and the syringe, and a second took a vessel full of fine fresh slacked lime, quite cooled down. The syringe-man having well battered his tree, the lime-man powdered heavily on the heels of it, until the whole was as white as lime could make it. And now, I may at once say, that out of a hundred bushes done this way, not a bud has been taken since, as far as we can discover; and I consider the invention ought to be placed on a par with the famous recipe of the famous Forsyth, and to be a fitting matter for the consideration of our Parliament; who, however, I much fear are too busy to think about Gooseberries.

But jesting apart, let me advise cottagers and others to try it in another year; for my part, I think I shall always do it before a bud is taken. Let me here remind our friends of the propriety of our annual top or surface-dressing, to Gooseberries and Black Currants especially, be it ever so little. By these means, surface fibres are constantly added, and the injurious effects of drought prevented; old thatch, rotting litter, leaves and a little manure blended, will accomplish the thing. We have proved the practice for many years. R. ERRINGTON.

WHAT SHOULD AND SHOULD NOT BE DONE IN THE SPRING.

If I were to say that we should take sufficient time to do everything in the right way, and that we should not hurry over anything we did in the spring, it would justify this heading of my letter; but I must go farther, although I cannot name one-tenth of the jobs that press for immediate attention, nor restrain the fast doers, who care not how the world goes round, provided they get every job through hand as fast as anything, no matter how *scamping* the work is got over, if you can put a plain surface on it for the time.

I was coming down the road, one day last week, and met a gentleman,—a great gardener, not far off,—and he asked my opinion on pruning some *Hybrid Perpetual Roses* that were planted last January, and also about some *Rhododendrons* which were planted five years since. These were old plants when he had them, and they were very bare at the time; but he was told they would soon take on in his new garden. New gardens, new brooms, and new dresses, do wonders, now and then, but not always! at least, all the time this garden was new these *Rhododendrons* took on nothing but barefacedness. After seeing there were no flower-buds of any account on these plants, I advised to have them cut down about the end of April; there are lots of sucker-like shoots, young enough and healthy enough, at the bottom of all the bushes, and that is a sign that the bare branches got too dry and hard to let up the sap, rather than any unhealthiness in the roots to hinder their part, and on that account I ordered all the branches, young and old, to be cut down to near the bottom sucker-like shoots, which are only from six to ten inches long, and I mention this to show a reason for an opposite course, which is given to-day in the part for the private correspondence, and also to let a cat out of the bag, where the poor thing has been for a long time.

If there were no shoots coming from the collar of these bare *Rhododendrons*, and that the tops looked green and healthy enough, one would conclude the bareness was caused by the plants being too close together at a former period, that the roots were all right, and that the bare part of the branches did not get into that hind-bound state which nothing cures so soon as cutting right down to the bottom; then there is no

fault in any of the parts, and it seems a pity that a plant without any fault at all should be cut down to the ground; no gardener of any note would do such a thing till he tried and failed with all the plans he could think of—so the healthy, but bare, *Rhododendrons* were ordered to be cut down to different heights, from five feet to within eighteen inches of the ground, they standing just now full seven feet high. But the puzzle is, why do they advise to have all the small shoots cut-in so many inches about the beginning of April, while the large branches are not to be touched till the second week in May, or to a later period, if they are worth keeping till they are getting out of bloom? The puzzle is no puzzle to gardeners, however; at least, not to some of them, for it is on the right application of the rule, or principle, which concerns this puzzle, or no puzzle, that one gardener exceeds another who has more advantages; and the rule runs through every branch of gardening in which plants are concerned, and yet no one writes about it; but the best way to break the ice about it is first to mention an opposite rule.

Early next June, if all is well, Mr Errington will put us all in mind of stopping the breastwood on wall-trees at such and such lengths; and, to do that as it ought to be done, he will be very particular in advising to have the top part of the trees, and all the "robbers" in any part of the trees, stopped first; in nine or ten days after that, he would have us go over the trees again, and stop the next strongest shoots, leaving the small fry and those about the bottom for some ten days longer; and the reason he gives is as good as the rule, that the small shoots may receive extra help from the supply which has been stopped higher up. Before his own vigorous growth stopped—I mean the growth of his body and limbs—they used to summer-prune all parts of a wall-tree the same day; but that made bad worse, the strongest shoots would push stronger than before, and the little ones got weaker and weaker every season, and when they came to the worst, people began to improve their ways, by stopping the supplies gradually, and what the strong lost the weak gained, and the more they gained, the fewer you could see of the very strong. Thousands of plants, besides fruit-trees, go through this style, or rule, of pruning every season; every strong shoot which is stopped during a summer's growth comes under the rule; and here, the rule of thumb is right after all—the finger-and-thumb-pruning during a growth being of the very best kind.

Now, what would half the world say if one were to recommend exactly the opposite way of pruning? To begin first to cut the smallest twigs on a tree, or bush; next, the intermediate ones; and, last of all, the very strongest? Why, without giving it a thought, they might reasonably say, that would be worse than no pruning at all; but just think over it awhile, and, if I mistake not, I shall prove to you, and all the rest of them, that this side of the question is the right one, nevertheless; and showing the opposite rule, in the case of fruit-trees, will enable me now to make you understand my meaning. I do not say that two rules can both be best; but each rule, though the very opposite to the other, is best in its own season; the first rule is the best in all summer-pruning with all plants; and the second is just as good, and fully as much called for in winter-pruning; yet we seldom think on this, and never write about it; therefore it was necessary that some one should make a direct experiment, to prove this winter rule, before the whole body should be asked to put faith in it on the authority of any one, and having little else to do, I thought I might try the experiment first. I have done so, and it is as clear as anything, and of universal application.

Against the west end of a retired cottage, on the

banks of the Thames, grows a beautiful plant of the Rose *Blairii*, No. 2. It was planted in 1841, or 1842, and now reaches fifteen feet high, and spreads accordingly. I received full permission to do with that Rose, and other strong climbers, just as I chose. Well, in November, I pruned all the young small wood along the bottom of this Rose to one inch, and I saw, that if I pruned the rest that day not one out of ten of these hard one-inch pieces would ever push again. I should have the old story of *Blairii* and bare bottom over again, and of that there was enough already. I went home, and never saw that Rose again till the middle of February, when I made a second turn at pruning, by cutting the second sized shoots all over the plant; these were cut to different lengths, of from six inches to two feet, and a few a little longer, where there were open places on the wall to cover: by this time, most of the top shoots, and the strongest, were nearly opening the top buds, and the little inch spurs I left in November as hard as an old bone had buds on them that I could just perceive, and no more, so I went off again without cutting any of the strong shoots. I left them to the first week in April, when everyone of them was more or less in leaf; the buds on the inch pieces had made some progress also in the meantime, and the buds on the shoots which were pruned in February were getting full also; now was the turn for shortening the strong shoots, and you would be surprised to see how few of the buds below half their lengths were swollen. All, except the last six or seven buds near the top of each shoot, seemed not to feel the influence of the season yet, and when I cut them to different lengths, taking away all the forward buds, what buds I left on those strong, luxuriant shoots were not then nearly so forward as those on the little spurs at the bottom of the wall, and some of the buds on the intermediate shoots were actually in leaf some days before the very top buds on the plant.

If you understand the force and value of having the buds on the weak lower branches as forward in the spring as those at the top of the tree, be it Rose, or Apple, Pomegranate, or *Polycarpus*, if there is such a tree, you will agree with me what shoots of a tree ought to be pruned in the spring, and which ought not to be pruned in the spring; also what trees and bushes ought to be pruned in just now, and what bushes, and trees, and plants ought never to be left unpruned till the spring. A weak, scurfy, scrofulous, or puny scrub of a tree, whether a Rose, Ribes, or Rosemary, whether for fruit, flower, or fume, should never be left unpruned after the middle of November in each year of its sickly life, and if pruned six weeks earlier than that the sickness is the more likely to vanish. A young, healthy, vigorous-growing tree or bush, ditto, ditto; or an old one which threatens to run out of bounds, ought not, on any account, to be pruned till late in the spring; never in the autumn; and as almost all trees exhibit parts that are neither strong, vigorous, or thriving, as did that very strong *Blairii*, No. 2, it follows as naturally as day follows the night, that there are very few trees indeed, within the garden, which ought to be pruned all over the same day, or the same week or month. In short, to keep in keeping with my text, I hold it to be sound philosophy to prune parts of a tree in the spring; and I affirm it as bad practice to leave the weak parts of a tree unpruned till the spring; and this rule or law holds good through the whole kingdom of trees and bushes, and through many of the smaller states lower in the scale; as, for instance, take a good specimen of a Scarlet Geranium, from which you wish to make cuttings just now, and if you understand the drift of my argument, does it stand to reason that you can improve it in shape, or equalise the strength, by taking off all the

tops, weak and strong, the same day or the same week. All the shoots are on the move now, and the strong ones will burst into new growth after cutting much sooner than the little shoots, and so sure as they do, the little ones will have a still less share of the rising sap, and besides being little, as they are, they will get crippled into the bargain, and die at last, if you do not cut them off by way of saving appearances.

It was only the other week that we had a new Geranium with two weak shoots and a strong one; this strong one flowered, and cuttings were made from the other two till we had them stumped nearly to the quick, six weeks before the strong one was out of flower, and cut down in its turn. Now nobody could tell, next August, if the whole three were not cut the same morning. You may very naturally inquire now, if that be so, how is it that they do not cut the large Geraniums which we see at the shows on the same plan, which they never do. There is no trouble in telling that. Nothing is so plain as *their* reason. Their plants, and all plants, never have all the shoots of the same size or strength—this is how they do it; they cut the smallest shoots much lower down than the strong ones, and they allow of only one, or, at most, two new branches to come from the bottom of the little ones, the rest are rubbed off; but on the bottom of the big shoots they allow five or six new shoots to come; then it is just like all the world over—a strong man will find as much difficulty in fighting against five ordinary men, or in providing for their keep, as a little man with narrow shoulders would find in pushing against, or in favour of, one or two; so it comes to the same thing, at last, with many trees and flowers, but never with Roses and most trees which require much looking after.

ROSE-CUTTINGS IN THE OPEN AIR.

The A B C of striking Rose-cuttings in the spring is to get forward little shoots, or, at least, short ones in a forward state of bud, and even if the top bud is in leaf it is all the better; this soft top is cut off very carefully, but not to the old wood; the rest of the swollen buds are broken off also, and what is left round the bottom of the broken buds may not be seen, but, rest assured, there are many little buds round most of them, and they will come in their turn. I could not see a single bud on the little spurs I left on *Blairii* when I pruned in November; but I could more than see them in February—I could then feel them; then you see, that by pruning off swollen buds of Roses in the spring you put the cuttings back, as it were, to November; and yet they are full of spring sap, and this sap must go somewhere, up or down; part of it will go down and make roots if the cutting is in a right way, and part will go to push the invisible buds into daylight. The cuttings are put into small pots, and close round the side in a firm compost of half sand and any light earth that comes in the way; the pots are plunged to keep them moist, for that is all that Rose-cuttings require in the spring. If they were put into sand, or soil, without pots, they would be either too wet or too dry, and when a Rose-cutting is full of spring sap, the least dampness will kill it in three days; if it is too dry it soon shrivels, so that there is a good deal of nicety about the thing, and may fail with them for awhile, till they get into the right way. But is it not the same in everything else? Who could make hooks-and-eyes for a dress at the first start? And the man who makes the needles could no more hem a silk handkerchief than I could, on the first or second trial. It is so with cuttings, and particularly so with cuttings of Roses in the open air at this season; but that they can be done is beyond all question. They must not have too much rain, even in pots, or too much sun, or too much easterly winds. When they are well-rooted by the end of May, they must be turned out of the pots

for the season, without disturbing the balls, into little holes in the border, which must be filled all round with as rich and light compost as one can make, and in October they are fit to be taken up and done anything with.

COTONEASTER MICROPHYLLA.

WHAT a pity that nobody takes this plant in hand to grow it in the right way; or, at any rate, to train it in a way that it would tell so much better than trailing along on the ground. It will come from cuttings of one-year wood if they are put in any week in the year, and one can always take them with heels. This month and to the 1st of May is a very good time to put them in. They will root in any light garden soil, which ought to be pressed hard round them. It does not matter much whether the bottom leaves are rubbed off or not, but, as it does not look workman-like to put leaves in the ground with any sort of cutting, we had better say, rub off the bottom leaves for a couple of inches, and press the earth hard to them. Cuttings of any length will do, and three inches is the right depth to put them in the ground, and other three inches out of the ground is the right length above. Then, if your cuttings are just six inches long, you are right, and, if longer, cut the tops to that length. If you can get a shady place for them they will hardly ever want water. Next winter or spring they will be rooted enough for moving anywhere. They make a beautiful hedge in a geometric garden, planted six or nine inches apart in this young state, or a foot from plant to plant if they are bigger; and the way to train is to put a row of pegs in the ground, along the line, about ten or twelve inches apart, and a foot high out of the ground; the branches are then trained or watted in and out between the sticks, as close as if you were making a hamper—this is to get a body for the hedge. Every other year you must put in longer and longer sticks, to get up to what height you want the hedge to be, and each season you wattle the shoots as before, and also cut-in the side-shoots from the bottom, on both sides. The hedge should be about a foot thick, and square on the top, or it may be sharp, like the ridge of a house. Nothing makes a neater or more architectural looking hedge than this plant; and with its red berries in winter, it looks as gay as a bed of *Skimmia japonica*.

Another most ornamental way of using this plant is, to make choice of an old plant, which has stood many years in the border, or rock-work, and to cut this plant down to the ground about the middle of April, not leaving one morsel of it above the ground. The strong roots will soon throw up a bunch of shoots, like a stool of Raspberries, and quite in a different way to the old plant—more like a young Oak or pollard Willow cut down in the spring. Choose five or six of the strongest of these, and cut back the rest, put in a stake, five feet long, and train up the shoots to it, just like a pillar Rose, and you never saw such a pretty pillar-plant in your life. I know one which is fifteen feet high, or might be, but the pole is only ten feet, and the shoots hang down from the top most gracefully. The sides of the pillar should not be pruned in too close, the more feathery it is the more graceful, and the more berries; but cut back all suckers for a good handsome pillar.

It is also a good wall plant if you once get it to run up; and by pruning it so as to have horizontal side branches, like a Pear-tree, it looks uncommonly well.

D. BEATON.

COMPARING NOTES.

SMALL GREENHOUSES ATTACHED TO DWELLING-HOUSES.

It is now getting on for two years since I had the last

gossip with Mr. Beaton. At that period he had been enclosing part, at least, of the back yards of some new houses with a roof of sheet glass, so as to give the tenants the convenience of shelter, and the luxury of a conservatory at command, a very fair per centage of additional rent being expected for the outlay. In suburban districts, and small country towns, the system, if more generally adopted, would, I believe, be profitable to landlords, and a source of great pleasure to tenants, and few, if any, could better than our friend give the subject such an importance and notice as to command attention. At that period he had also been visiting some sawing establishment at Brentford, where sash-bars, &c., were prepared with something like lightning rapidity. As a vast number of questions respecting the cost of small houses are continually put, which these, like myself, living in the country are unable suitably to answer, locality and circumstances, as to materials and carriage making such a difference, it might be interesting to know for what good greenhouses, lean-to's, and detached, of various small sizes, could be built for, using the best material of all kinds, and everything well finished; and what the difference would be with inferior glass, &c. Many have quite scouted the idea of a five pound greenhouse, an account of which appeared in THE COTTAGE GARDENER some time ago, but they forget that the whole materials were of the commonest description, and the most of the work superintended, if not done, by the owner. If it would be desirable to give more definite information on this subject, our metropolitan coadjutors would be the most suitable persons to supply it.

The other day I was in one of a whole row of miniature greenhouses which interested me very much. A few weeks previously, when coming out of a merchant's house, in the same market-town, I was accosted by a young lawyer, who wanted to know a great deal about the treatment of an Orange-plant. Questions on his side were so met by the activity of the inquisitive bump on mine, as to the position and the circumstances of this Orange-plant, until the discovery was made that it belonged to a young lady, who prized it highly, and that she kept it in her greenhouse. On one thing he was wholly deficient in information—he knew nothing of the heating of the house, and yet he knew that the severe frost had hurt none of the plants. I was just at the point of passing a joke about the consultation fee, when the thought that there might be a hidden mystery about orange-blossoms kept me silent. The knowledge of an additional plant-house, however small, was to me interesting, as I thought I pretty well knew something of all the plant-houses in the town. But in this I had reached conclusions without a due knowledge of the facts and premises.

A great deal of building has lately been going on, and the house in which I was the other day was one of a considerable number facing a continuation of a new street, built by and belonging to one landlord, and all uniform. The houses are small, and, in every sense, self-contained; the yards or gardens being all distinct and divided from each other; they are two stories in height, I forget whether with or without attics. On entering the street-door, the passage takes you past the doors of the front and back parlour, and rounding the staircase into the kitchen; this is a separate building, joined to, and about half the width of, the main house; but the gable end, containing the fire-place and chimney, standing at right angles with it. Keeping this in view, it will at once be seen, that between the kitchen of one house and the kitchen-wall of the next a space opposite the window of the back parlour would be left of something like eight feet by fourteen. This window has been changed into folding glass doors, the space is roofed with glass, and a glass door and end lets you out

into the neat little garden. There is a door, of course, in the kitchen for the same purpose.

In the small house in which I was the other day (March 6), there was a narrow walk from the parlour, down its centre, to the door in the end, with a neat border on each side. Mignonette had been growing in these borders all the winter, and was nice and green, but did not flower very well, owing, as I suggested, to a want of air, and to being such a distance in the dark months from the glass roof. Several strong Geraniums, of the *Giant Scarlet*, were growing vigorously against the wall. Fuchsias, and variegated Geraniums, were quite healthy in the borders; a Passion-flower was green and flourishing, and growing vigorously against the wall; and two Vines were just bursting their buds. The intelligent owner said, they never thought about the frost, though he regarded all with that zest which the enthusiasm of tending plants and flowers with our own hands alone can inspire. The situation of the kitchen chimney, in the centre of one of the boundary walls of this miniature house, had kept the frost entirely out during the late cold weather. In hot weather there are plenty of means for admitting air, by sliding one or both of the sashes, as far as I understood, and opening the end door. I found out that the owner of the Orange-plant referred to lived in one of these houses. I have been thus minute in the description of this block of houses, as these miniature greenhouses would cost but a small sum in making, or keeping, and would be much coveted by all who could spare a few hours from the hurry and bustle of business.

A few hints and remarks may be added in conclusion.

1. From adopting such a plan for small houses, all the bother of *heating* is avoided; if the houses were *wider*, it is questionable if the chimney from the kitchen would be sufficient. Even in cold nights, when a little clear fire was kept in the grate on retiring for the night, a damper placed in the chimney so as to allow a small opening, to prevent the air of the room being contaminated, would prevent the heat freely escaping at the top.

2. The house having light admitted merely at the roof and the end, low plants on the border will not thrive nearly so well as those more elevated to within three feet or so of the glass, either by means of small stages, baskets, or vases.

3. Tall standards of such things as Tea Roses, Fuchsias, Scarlet Geraniums, *Salvia splendens*, &c., would make an interesting appearance, allowing their heads to occupy the most of the space above the head-room next the parlour door.

4. Vines would require to be taken up the wall, and then trained, either longitudinally or cross-wise, about fifteen inches from the glass, but if allowed to monopolise the roof the room would be made too dark. Blue and purple Passion-flowers, suspended in festoons from arches, would also have a very pleasing appearance.

5. Camellias and Oranges would also do well, either as tall plants, or as trained over and covering the walls. The greatest part of the *Cactus* tribe would also answer well. How nice, for instance, would *Speciosa Jenkinsii*, &c., do on one wall, and *Speciosissima* and its varieties on another; while strong shoots at the top could be grafted with *Mallesonii*, *flagelliformis*, &c., and look nice dangling from the roof.

6. One thing necessary to success would be the *aspect*. North should be entirely avoided; it would only be fitted for Mosses, Ferns, and keeping plants, bought in bloom from a nurseryman. The south, south-east, and south-west would be the best, but we would not throw cold water altogether on either *east* or *west*.

7. The modes of planting and managing such places would be endless, and the greater the variety not in one place, but each different, the better. The peculiar circumstances of large cities, in which a man knows no

more of his next-door neighbour than if he lived in the wilds of Australia, has not yet thoroughly penetrated our country market-towns, though there be a tendency in this direction from every great increase of houses and inhabitants. There is still a considerable spice of neighbourly feeling, and a desire to cultivate the social virtues. Any apparent want of this proceeds not so much from any inherent feeling of exclusiveness as the want of a good excuse for breaking in upon the privacy of our neighbours. Now, what a fine opportunity do these miniature greenhouses, furnished differently, afford for breaking in upon the icy coldness of a genteel, stilted reserve. I, myself, have often got into kind, sympathetic speaking terms, by going to see and expressing admiration of a plant in a window. Well, on my word, there goes Mrs. Prudence, having summoned-up courage to knock at the door of Mrs. Thrifty!! A distant nod was all their previous recognitions! "I have ventured to ask the favour to see your beautiful Camellias." "O, most welcome; most welcome;" and away the ladies go, talking about flowers, as *only* ladies *can* talk, feeling a stronger and stronger mesmeric sympathy getting hold of them reciprocally; and if the interview does not actually end in sipping together the "cheering cup that not inebriates," Mrs. Thrifty has received and promised to act on the invitation, by-and-by, to see the splendid Fuchsias of Mrs. Prudence, and so the kindly, social feeling, based on intelligent perceptions of the beautiful in vegetable nature, spreads from one house to another. I know nothing of the builder or owner of the block of houses referred to; but I believe the idea will be successful, whether viewed in its remunerative, ameliorative, or pleasure-imparting aspects. R. FISB.

THE ANTIRRHINUM.

(Continued from page 442.)

Cuttings in Pots.—As I have said that Antirrhinums should be exhibited in pots, it is but right that I should describe the way they ought to be grown so as to show them off to the best advantage.

Soil.—The first thing to provide is the soil. Whoever grows florists' flowers will be always on the look-out for good loam, and I need scarcely maintain that the best is the turf from an upland pasture, taken off about two or three inches thick, carted home, and laid up on a heap for a year, to cause the grass roots to decay and mellow the soil. If this heap is chopped and turned over four or five times during the year, it will be sweeter, and better pulverised, and in finer condition for use. Of this loam take three parts, and of well-decomposed leaf-mould one part, and sandy-peat one part. If the grower has no leaf-mould he may use the same quantity of hotbed manure, but in that case it must be exceedingly well decomposed, in fact, reduced to a fine black mould. Taking into consideration that the Antirrhinum grows well on old brick-walls, a small portion of old lime rubbish, slightly sifted, will be of service to the plants mixed amongst the compost. All these matters being duly prepared in sufficient quantity, let them be brought under shelter to dry some time before the potting season.

Pots.—The second article to provide is the right sized pots. I have grown and bloomed them very tolerably in what are called large 48's, which are 5½-inches diameter; but for exhibition purposes, or to grow them finely for private pleasure, they ought to be planted in 8-inch pots; and as these plants have strong roots that run deep into the earth, the pots should be of the deepest size made.

Potting.—The proper time for this operation is early in March. The plants should be then just beginning to push up three or four strong shoots from the base of

the plants. These must be taken great care of, for they are to produce the flower spikes. Drain a pot well, and place a little moss upon the drainage to prevent the soil from choking it up, then fill the pot high enough for the ball of the plant to be nearly level with the rim of the pot. Turn the plant out of its present pot, and remove the old drainage carefully out from amongst the roots. Open these out without breaking them, and work the fresh soil amongst them. Fill the soil up round the ball level with the rim, covering the ball about a-quarter-of-an-inch, then shake the soil down by striking the pot smartly on the bench, and the potting of one is finished. Proceed thus with all the rest, and when all are finished give a good watering, and place them in a cool pit or frame. Protect them from severe frosts by a covering of mats or some other material that will keep it off, but open the frames every day, as early as the weather will permit to keep them cool. This is a grand point; for if they are drawn up into weak growth there will be no fine bloom. Should any of the plants produce one or two strong shoots, these ought to be stopped, to cause them to produce more shoots. Every plant should have at least five shoots for bloom. When these strong shoots have made some progress, and have a fair proportion of leaves, then all the small, weak shoots should be cut clean off. They make the very best cuttings.

After-culture.—As the plants grow they must be well supplied with water, and when the pots are filled with roots a weak solution of dung-water will be serviceable. The great thing to aim at, is to produce a strong, healthy, bushy plant before the flower-spikes appear. It may be necessary, where the shoots of any variety are weak, to place small green sticks to support them, or prevent the wind from breaking them; though I abominate sticks, and would never use them, except in cases of necessity. It might happen that some varieties cluster their shoots together, and, in such a case, sticks must be used in an early stage—place a stick to each shoot to spread them out, leaving the tallest in the centre.

As the season advances the plants should be placed in the open air, on a bed of coal ashes, in a situation sheltered from the wind. Just before the blooms begin to open cover the plants with an awning of canvass to shelter them from the sun and heavy rains. To produce a number of fine blossoms at once, nip off the very tip of each spike whilst they are growing. This will encourage the blooms greatly, and bring out a greater number of fine blooms at once, and thereby ensure a finer exhibition.

No flower will travel better, when in bloom, than the Antirrhinum, yet, when the distance they have to be conveyed is considerable, it will be safer to place a stick to each spike, placing them at such a distance that the blooms will not rub against or touch each other. They should be packed in a box, and each pot secured so that it cannot move, space being allowed between each so that the plants do not touch each other. The front of the box should open, and the plants then can be taken out easily and safely. Any country carpenter may make such a box easily. When the plants reach the place of exhibition, take them carefully out of the box, remove all unnecessary sticks, and trim off any bruised leaves or flowers, and, if necessary, give them a little water to keep them fresh through the time of the exhibition. They must then be left to receive the adjudgment of the censors. I can confidently predict, that whoever will bestow all the above-described attention will be agreeably surprized with the fine appearance the Antirrhinums will make.

(To be continued.)

T. APPLEBY.

SCRAPS FROM MY NOTE BOOK.

HEATON PARK is near Manchester, and the seat of Earl Wilton. This place, though within the reach of the smoke of the great cotton factories of that town, always exhibits marks of good gardening. I visited it during the great snow storm in January, and found due preparations for producing early crops of forced fruits. The *Cherries*, especially, were promising, being full of blossom-buds; and to prevent, or rather destroy, the red spider and the black aphides, Mr. Shuter had painted all his Cherry-trees with lime-wash, and said he always made that a practice, with complete success. In the *Pine-pits* I observed several fine fruit of the variety *Black Prince*. This was raised, I believe, by J. Entwistle, Esq., at his place near Roehdale. It is a noble fruit, and worthy of general cultivation, though some say that it ripens unequally.

The excellent method of having double fronts to the *Vineries* is here practised to a great extent. By thus isolating the Vines the houses can be made use of for plants requiring heat, such as Pines and stove plants. The outside front windows are so contrived that they can be opened to keep the Vines cool and at rest; the inner windows are kept close, to prevent the heat from reaching the Vines. This is much superior to the old method of twisting the Vines out of the front windows and exposing them to the cold and wet of the winter. When I was gardener at Horsforth Hall, for the Rev. James Armitage Rhodes, we had to turn out the Vines through the front windows, and often had the misfortune, yearly, to twist one or two off just where the roots commenced. The hothouses here were formerly heated with rows of very small iron pipes, on the principle invented and patented by the late Mr. Perkins. The great fault of this system is the great attention it requires, and the danger of the pipes bursting. It is now pulled down, and the ordinary four-inch pipes substituted, which are found to answer much better, requiring less care, and giving a more equal temperature.

There is a very fair collection of my favourite plants the *Orchidaceae*. There is not only a goodly lot, but they are in good vigorous health. The following were in flower:—*Lycaste Skinnerii*, a good variety; *Leptotes bicolor*, with its pretty spotted flowers; *Oncidium ornithorhynchum*, several spikes of sweet-scented flowers; *O. Bauerii*, many spikes; *O. pubes*; *Phaius grandiflorus*, strong, with many spikes; and several plants of that useful winter-blooming plant, the *Stenorynchus speciosus*.

PENRHYN CASTLE.—This is near Bangor, North Wales, and is the residence of Colonel Pennant. The gardens here have been greatly improved within the last seven years, and are still making progress. In early crops, my Note-book says—Grapes, very forward; some in pots, were so far advanced (Jan. 6th.) as to have been once thinned. In one house, the Vines on the rafters were just coming into bloom, and showed plenty of bunches. I was much struck with the rich dark green colour of the leaves; I never saw a finer colour at any season of the year. I ascribed the colour to the clear glass and the narrow ribs between it. There were some excellent Pines, and some large fruiting plants, in excellent health. They are grown in low houses, and are planted out in the Hamiltonian method.

But the point in gardening that pleases me most here are the Espaliers covered with *Pears*. They are simply formed with iron uprights, and five or six iron rods stretched through holes in the iron posts. The trees are trained horizontally, every shoot as regular as possibly can be conceived, and furnished with blossom buds throughout. In all my travels, I never saw anything like them, so even, perfect, and regular.

In the Pine-stoves, on the curb-stones I noticed several plants in full flower of that pure white blossom, the *Balsamina latifolia alba*, a plant of great beauty at this season of the year. It is a good addition to our winter-blooming plants, but requires plenty of heat and moisture to keep it in health and bloom.

In a cool Peach-house I noticed a great quantity of bedding-out Scarlet Geraniums. These, Mr. Burn, the gardener, informed me, had been propagated in a very simple manner. The cuttings were taken off in August, stuck thickly in pots, and set on a gravel walk, behind the espaliers alluded to above. They were never watered, but just took what fell from the clouds, and every cutting grew, and those that I saw were the stock thus, I might almost say, carelessly stuck in.

RUFFORD HALL, near Ollerton, Notts, the seat of the Earl of Scarborough; a fine old place, with a good garden. The wall trees are uncommonly well managed. The Seymour system of training the Peach consists in not allowing any shoots on the *under* side of the main strong branches. It is a beautiful regular mode of training, and is much practised in various places in Yorkshire; but Mr. Chapman, the gardener at Rufford Hall, has adopted the singular mode of not allowing any young shoots to remain on the *upper* side of the main branches; and he assured me, he found the sap more regularly distributed, and the young shoots more equal in strength, than by Seymour's method. The fruit was regular and ripened equally throughout the tree. Peach-growers may try this, and thus prove whether there is any advantage in it. T. APPLEBY.

CARROTS AND THEIR CULTURE.

THERE are few things more precarious, as a garden crop, than the Carrot, as, from a variety of causes, a good crop cannot always be commanded on ground that seems capable of producing most other things in great abundance, for though there is every reason to believe the parent of the cultivated variety is indigenous with us, yet the high state of cultivation to which it has been brought, by breeding in and in, has so far diminished its hardihood, or made it less accommodating in its habits, that we often see it refuse to grow on ground that other crops flourish upon. This state of things is certainly, in a measure, owing to the improvement effected on certain parts of it which require a certain amount of food of just such a kind as all land does not possess in the requisite quantity, and though there be a superabundance of a contrary kind, still the habits of the plant, or rather its constitution, refuses to benefit by it. Another reason of the failure of the Carrot crop arises, not unfrequently, from the attacks of enemies against which it is not always sufficiently robust to protect itself; this occurs more often in old gardens, or grounds rich in manure and other compounds of a like nature, but it may be seen in newly broken up grounds as well. However, we occasionally see good crops in circumstances similar to both the last named; and it is not always that the eye of the experienced can pronounce whether a soil pointed out to him is a good Carrot-bearing one or not, for it often happens that the most unpromising do well, while the better-looking one falls off sadly. Nevertheless, if we look to the best districts where Carrots are produced in quantities, we shall glean a little of the reason "why they do so."

I believe I am right in saying, that a great bulk of the Carrots used in the great Metropolis are grown on the southern part of Bedfordshire and its adjoining county, Herts. These roots are grown on land, which, at all seasons, does not present such a fine, mellow surface

as other lands elsewhere, which are not favourable to this crop, the soil being a light hazel loam, rather than that sandy or gravelly soil with which we are too often wont to associate the name of Carrot. Nevertheless, a certain amount of good working and good management is requisite in all cases where good crops are expected. Now, as every garden does not possess a soil so nicely balanced to the growth of the Carrot as that of which I speak, it may be well to mention a few of the "points" which tend to secure a crop, noticing, at the same time, some of the causes of failure.

In the first place, we shall suppose the only eligible site for a Carrot-bed is in an old garden, which has been under crops of various kinds for many years, and received a liberal allowance of manure in the ordinary way. This soil, rich in humus, which, doubtless, grew excellent Cabbage, Lettuce, and similar crops, is not exactly the one for Carrots, it being too rich, and most likely abounds in the enemies so much to be dreaded in the Carrot crop. Now, the only way to manage this well, is to consider some time before-hand where the Carrot-bed is to be, and have the ground trenched in the autumn, burying a considerable part of the top soil at the bottom, and mixing some of the bottom with what remains at the top: this is done, of course, only in such places where a sufficient depth of soil is to be found, and must not be carried out too far, neither must it be delayed until just before sowing time, otherwise there will not be time for the earth to get thoroughly pulverised by the action of the air, as well as rendered sweet, and capable of germinating and supporting delicate seeds like the Carrot. Now, in addition to the trenching just spoken of, it would be prudent to take advantage of two or three favourable occasions when the top of the ground was dry, during the winter, and dig it all over, one spit deep; the last digging might only be a sort of stirring, the top side remaining as top side again. This movement of the soil is best done when a slight frost allows the ground to be trod upon without pressing it, while the tool of the operator is still able to work. It is almost needless to say, that at the last the ground ought to be made very fine, and advantage taken of a fine day to sow the seed; the crop may be fairly expected to be good, the season being favourable, and all vermin kept at bay. But it would be wrong to say that it would assuredly be good, for old gardens are not always the best places for Carrots. I ought, also, to mention, that it would be well (where a choice can be made) to have the Carrot following some other crop than one of the Cabbage family, for they generally leave behind them a train of enemies which prove fatal to the Carrot. Nevertheless, there may be instances where this may be necessary; in such cases, more energy in preparing the ground, so as to free it from such impurities, accompanied by a favourable season, will generally effect a cure; lime, of course, being also an ingredient not to be dispensed with.

The *Early Horn* variety of the Carrot is supposed to contain the best table qualification, but it is smaller than the other; the *Orange* is, perhaps, the next best, the *Altringham* having, of late years, appeared so hard and unpalatable; but much depends on the season, the kind of soil it is grown upon, and other conditions, that I have no doubt the *Altringham* may be a favourite when the other kinds are condemned. In one respect it differs from many others—there is a much larger portion of it out of the ground than there is of the others.

In summing up this subject, it is proper to observe, that when all means of securing a good crop of Carrots from wire-worm, &c., have failed, a partial one may be found by sowing this root with a crop obnoxious to the vermin spoken of; as I can well remember, in my younger days, seeing *Carrots* and *Leeks* sown in alternate rows; the latter produce, being offensive to the wire-worm,

formed a sort of protection to the Carrot, which grows pretty well under such treatment. A similar plan was in practice, about the same time, of mixing Carrots and Onions together; but the latter were speedily overgrown if the latter did anything like well. Still, it was remarkable to notice the fine, healthy Carrots on an Onion-bed, while scarce one was to be seen on the plot allotted to themselves alone; but it is needless to say, that when sown in an Onion-bed they greatly mar that crop, and not unfrequently all but destroy it.

It would be as well here to caution the inexperienced against allowing his Carrot-bed to remain too long unthinned, for the roots penetrating deeply leave long conical holes in the earth, which the enemies to the crop find a convenient lurking place; in addition to which, allowing a superfluous plant to remain beside the permanent one, depriving or robbing it of much of that food so necessary to its existence, cannot be otherwise than hurtful; and we all know that vegetation of all kinds has a much greater dislike to follow in the immediate footsteps of itself, or its next of kin, than to that of a stranger. It is, therefore, imperative on the cultivator to have the crop freed from all incumbrance as early in the season as possible, and though they need not at first be thinned-out to the full extent, they ought never to remain so thick as to elongate their leaf-stalks in such a way as to cause them to fall down when the thinning day does come. I may add, that for garden purposes, drills, fifteen inches apart, will do for the *Early Horn*, but the larger kinds may be a little wider, if necessary. Weeding, surface earth-stirring, and the like, I regard as such generally well-known maxims, that I do not repeat them in every instance, but in this, as well as in all others, it is an imperative duty where a successful result is anticipated. J. ROBSON.

ECONOMY OF THE FARM-YARD.

(Continued from page 436.)

WHILST I am treating of the appropriation of old Farm-buildings, and their better adaptation to improved management of the manure, &c., the accommodation for Farm-Horses must not be overlooked. Even at the present day, in different parts of the country, may be seen the cart-horse stables so constructed that the urine which flows from the stalls passes away into the open yard, and only contributes in a slight degree towards the value of the manure therein. To remedy this waste, I propose that a tank be sunk at one end of the stable, the dimension of which should be four feet wide, four feet deep, and eight feet long; this will be sufficient for a stable of six to eight horses, and may be made with bricks faced with cement, and with lifting coverlids, and the drain from the stalls should be constructed with fall sufficient to take the urine away quickly. The tank should be occasionally supplied with ashes, or other loose earthy materials, which, as fast as they become saturated, may be removed, and held in reserve as manure for ordinary purposes, or, in case it is desired, the contents of the tank may be used as liquid-manure for grass and meadow land.

There is yet another mode of accommodation for Farm-Horses, which I have adopted in my own stables for several years, and which I continue up to this time, finding, as I do, that it answers well, both in securing manure, and preserving the health of the Horses. When

I commenced the experiment, I had the old stone floors of the stalls taken up and relaid at a depth of fourteen inches below the level of the passage behind the stalls; the depth of fourteen inches across the stalls being gradually diminished until it met the old level of the floor in front, but the depth being continued, with little diminution, until it reached the footway behind the stalls. I then filled the stalls up to the level of the passage with loose loamy earth, and kept it well covered with straw, which was removed daily, and fresh litter supplied as cleanliness required, in the same manner as is usual in stalls with pitched floors. The earth is allowed to remain until it becomes saturated with urine, and begins to throw off the ammoniacal vapour. In the summer months, when the Horses eat green food, the earth requires to be changed about every six weeks, but in the winter, when the animals live on dry food, it may remain from eight to ten weeks. The advantages of this plan are, that the most valuable and volatile portion of the urine is completely absorbed and deodorised by the earth, and preserved for the purpose of manure; and this, at the same time, greatly purifies the atmosphere of the stables, and effectually removes the obnoxious vapours always existing, in a greater or less degree, in stables having pitched or paved floors, and which is found so prejudicial to the health of the animals. The out-door portion of the pens for Cattle, Pigs, &c., alluded to previously, should be made to incline towards the centre, or that part of the yard where the manure is kept, as it were, in store, in order that the drainage may circulate amongst and improve the general mass. When the manure is removed to the field, either from the yard or from the heap, it is desirable that the earth should be equally mixed with the straw portion of the dung, in order that the effect upon crops should be equal throughout the field: for I hold the opinion that a cart-load of earth which has been saturated during the accumulation of dung upon it in the cattle pens, will be found to contain more than double the amount of ammonia than the like quantity of straw-made dung.

The whole of the foregoing part of this paper has relation entirely to the making of old and ill-shaped yards and buildings as advantageous as possible, in cases where circumstances preclude any rearrangement, which would incur a considerable expenditure of money. I now propose to consider the comparative advantages of some of the most modern and best constructed Farmsteadings. Within the past seven or eight years a great number of modern homesteads have been erected in different parts of the country, and although most of them differ in design and arrangement of buildings, &c., yet one great feature prevails in all, and that is the desire to adapt the buildings, yard, &c. to the requirements consequent upon the general improvement in farm practice, in relation to the feeding of animals, preserving and preparing corn, and the manufacture of manure. The immense improvement exhibited by some of these recent structures over the old farm buildings is very striking, and one of the chief and most advantageous arrange-

ments connected with them, is the facilities for box feeding, which is adopted in the feeding apartments for Cattle, Pigs, &c. In some of them I have noticed a mixed system of management, some animals being stalled, others kept in yards with shed attached, and in all cases where stalling is practiced tanks are used to receive the liquid drainage.

The use, however, of the liquid-manure after it is obtained, and the manner in which it should be applied to the land, has been for some years a matter of much dispute between some of the most enlightened agriculturists of the period. My own opinion on this subject is, that whilst we can purchase guano, bones, &c., at the present prices, it does not pay for the labour to mix ashes, and other dry materials with the liquid, for the purpose of converting it into a drillable state, nor do I think it answers to apply it to grass land in a liquid state, unless it is highly-diluted, in which case, the quantity being so much increased makes it desirable to use it near the Farm-stead, where but little cost is incurred for carriage; it may, however, be used with advantage in this diluted state with the liquid drill. The mode of littering the boxes is important, both for the health of the animals, as well as making manure. The plan of cutting the straw has been tried, and found not to answer, unless cut into unusually long lengths, either for Pigs or Cattle; the former rout it up, and the latter, from their weight, sink into it in the act of moving about, both these causes being sufficient so to disturb the manure as to keep it in a fermenting state, which taints the atmosphere of the boxes, and proves prejudicial to the health of the animals, at the same time setting free the ammonia, the most volatile, yet the most valuable, portion of the manure. These disadvantages are completely avoided when the boxes are kept supplied with a moderate quantity of straw in the ordinary state. The method of feeding animals, and allowing them to lie on hoards, or grating, whereby the manure is dropped on ashes, &c., has not met anything like general approval, yet the idea, I think, should not be entirely discarded, for in pasture districts, where little or no bedding can be procured, large quantities of good manure may be obtained, and the accommodation thereby furnished is certainly preferable to the old method of stalling, whereby nearly all the manure was lost, and the animals allowed to lie down in their own excrement.

The best mode of management of the manure when moved from the stalls, boxes, or sties, has been variously advocated even by scientific men, and by those who have designed modern farm-yards, &c.; some deem it best to keep it in the dry by a covered pit, into which the liquid-manure is allowed to run from the stalls, &c.; others advocate the open and uncovered pit; but I entertain the opinion that it should be carted to the heap, and the horses and cart allowed to pass over the mass with each successive load, it will then be firmly pressed, fermentation will be diminished, and it may be covered with earth when the heap is completed.

JOSEPH BLUNDELL.

(To be continued.)

THE CONTRAST.

By the Author's of "My Flowers."

"REMEMBER thy Creator in the days of thy youth, while the evil days come not," is a solemn charge to the sons of men. Terrible is it to see the hoary head, when it is not "found in the way of righteousness;" and beautiful, glorious is it to see the youth giving his earliest and best ways, the first fruits of life and strength, to the service of Him, who has so emphatically said, "My son, give me thine heart." The following sketch is from the pen of our kind friend who has so often helped us to pleasure and profit.

"There now reside, in a flourishing town in the midland districts, two mercantile men, whose progress in life has been very similar, inasmuch as they have both risen from small beginnings to be men of large worldly substance. One, however, is a very aged man, and the other in the prime of his days, who, though healthy, is not nearly so rich as the elder. The rise of the younger, whom we will call Mr. Smith, has been most remarkable. His grandfather was well known in the town as a vendor of refreshments, which he carried in a basket on his arm among the market people on a Saturday night; and his peculiar cry, by which he attracted the attention of his customers, is well remembered by many to this day. By the help of some friends; his grandson obtained admission into a local charity school, where he received an education sufficiently liberal to enable him to be fitted for an apprenticeship to merchants in the same place, at, I believe, a small weekly salary. Being a steady, industrious youth, he gained the confidence of his employers, and was engaged by them, at the expiration of his apprenticeship, as an assistant, in which situation he saved money enough to enable him at last to commence business on his own account.

"Mr. Smith was a God-fearing man, and felt, as all real Christians must feel, that money is a talent which will have to be accounted for at the judgment day. Instead, therefore, of wasting his gains, he spends them to the glory of God, and the good of his fellow-creatures. I have now lying before me the prospectus of a plan for the execution of the building of an establishment, which he has already, for some years past, supported on a humbler scale, at the cost of several hundreds per annum. The prospectus referred to is headed by this benevolent individual with a subscription of £1000. This is only a single instance of his many public benefactions; his private charities to the poor, and for religious purposes, are upon the same liberal scale. He is, indeed, a pattern of Christian philanthropy, and has gained the veneration and esteem of rich and poor: "When the ear heard him, then it blessed him: and when the eye saw him, it gave witness to him. Because he delivered the poor that cried, and the fatherless, and him that had none to help him. The blessing of him that was ready to perish came upon him, and he caused the widow's heart to sing for joy."

"How painful is the contrast exhibited by old Mr. Evans, the other merchant referred to! a man of treble the wealth of Mr. Smith. Alas! where is the poor man benefited by his benevolence? or the public charity enriched by his contributions? Echo must indeed answer, where? His residence is situated about a mile-and-a-half from his place of business, in the midst of a pretty rural village. The house itself is large, and would be handsome, if there was not a bleak, cold look about it, indicative of the man who dwells within. The garden is only half cultivated; the gates and fences are in a broken and tottering state; iron palisades have their heads twisted off; hinges have given way, and gates swing and bang about at the mercy of the wintry blast. All this is a matter of little importance to old Mr. Evans, for his eye only rests occasionally upon them, and then only on a Sunday afternoon, or very early on a summer's morning, or very late on a summer's day. Business is all he cares about; can he but get gold, he cares for nothing else. It is true he sleeps at home, but that is all; he invariably leaves it at a very early hour, both in summer and winter, without seeing any of his family, except the servant who prepares his breakfast; and returns at night after all are gone to rest, except the same domestic who sits up to let him in. For weeks together, his daughters (he is a widower) have only seen him on a Sunday, and alas! then only on a part of the day; for as one sin leads to another, as a natural con-

sequence, so has covetousness, in his case, led to sabbath-breaking. On the early morning of that holy day, old Mr. Evans may be seen vending his way to town, generally along a bye-path, for he seems somewhat ashamed to meet the gaze of the church-going inhabitants. His letters have to be read, and his ledger, very probably, examined, before he feels at liberty to inhale the fresh breeze of his country residence, or to bend the knee at the Throne of Grace. So pass his days, morning, noon, and night, coveting after gold; and having gained it, holding it with a clutching grasp which nothing can loosen; no other matter seems to engage a moment of his thoughts.

"Penurious in the extreme, he has gained a nickname, significant of his character, by which he is universally known. As he passes along the street, clad in an old Macintosh, which has apparently borne the brunt of weather for an indefinite number of years, as he never on any occasion indulges in the extravagance of a carriage, whether chaise or cab, the mother turns round and points him out to her child as miserly Mr. Evans; and the young man throws out a jeer and a joke to his companions at his expense.

"In a few months—years it can scarcely be—days, it may, indeed, be, and Mr. Evans will be gathered to his fathers; sighed over by the thoughtful, sneered at by the scoffer, and lamented by none. Where then will be his riches, and what his answer to an offended God?"

Where, and what, indeed! Readers, a solemn and instructive lesson is laid before you. Here is the man who heapech up riches; who layeth up bags of gold; who hastes to rise up early and late takes rest; who pulls down his barns to build up greater ones; who shuts up his bowels of compassion to his "poor brother," whom the Lord has given into his charge; who makes "gold his hope," and says "to the fine gold, Thou art my confidence." Even in this world he has no reward; his riches profit him nothing; he has the curse and not the blessing of the stranger and the fatherless; even men do not speak well of him. But what shall the end be? "Thou fool, this night thy soul shall be required of thee!" Consider the end of him whom the Lord himself calls a "fool." Consider the fate of him to whom the Lord himself says, "Inasmuch as ye did it not to one of the least of these ye did it not to me!" What labour it is for the meat that perisheth! If we laboured thus for that "which endureth unto eternal life,"—think of the peace and joy we should have now! think of the rest and security we should have, even while on earth, and "the end, everlasting life!"

Let the contrast between the two merchants satisfy us which is the path of pleasantness and peace, as well as safety. Godliness has "the promise of the life which now is, and of that which is to come." Godliness, springing from faith in Christ, as a blossoming branch from "the root and offspring of David." Think of the one scattering, yet increasing; think of the other, "withholding more than is meet," yet poor, and unblest, and solitary! Remember, works cannot save us! They cannot buy eternal life; nothing but the blood of Jesus Christ did that, or can insure our everlasting safety; but they follow us, and rend us in pieces, when we are not clothed in the wedding garment, which saves us from every accusing adversary. Readers! may we be found in the way of holiness, for that only is the way of peace. "He that trusteth in his riches shall fall; but the righteous shall flourish as a branch."

THE GARDEN PEA AND ITS CULTURE.

I FEEL so much delighted with those excellent, useful, and interesting papers by Mr. H., on the merits and demerits of the Pea, that I hope he will not stop when he gets to the end of its varieties, but continue onward, as opportunities may offer, through all our culinary varieties of vegetables. It is of the utmost importance to us practicals to have such really trustworthy information placed before our eyes at such a cheap rate as THE COTTAGE GARDENER does it.

I admire the plan of Mr. H. in giving us the synonymes of these various varieties, and, of course, we know, and duly appreciate, that it gives the writer much pains-taking trouble, and that it saves the reader much of disappoint-

ment and trouble. To show the value of synonymes being published, let us remember the old blue aprons knew an evergreen as the *Cupressus disticha*, for so it used to be called in the books; then some other author christened it *Schubertia disticha*, and the plant was dispersed about by this name, and by the time it became familiar to us it was changed again into *Taxodium distichum*, and the young gardener knows it by this name, but never, perhaps, heard of the other designations. On the other hand, the old gardener knew it by one of the other names, but never heard of its being changed into a *Taxodium*! Then, no wonder at the old gardeners and the young beginners being heard so often contending as to which is right about the names of plants. Both, of course, are right and both wrong, for the want of knowing more.

Now Mr. H. saves all this trouble, as far as the Pea is concerned, by giving us all the names that each variety has been popularly known by, and very nicely describes its merits and demerits.

I quite agree with him with respect to the value of the *Ringwood Marrow*. This pea I have grown for many years, and have taken many a first prize for it at our horticultural shows. When I first grew it, I used to save my own seed of it, fearing I might not be able to depend upon getting it true in our seed shops; but now, finding I can do so, I have discontinued this practice of saving seed.

Seed-Sowing. I always sow two, three, or even four kinds of Peas at my first sowing, but for years have placed the greatest confidence in the *Ringwood Marrow*, but also I sow a few of the *Early Emperor*. This year I have sown the following kinds:—*Ringwood Marrow*, one quart; *Bellamy's Green Marrow*, one quart; the *Emperor*, one pint; having two other kinds recommended to me, caused me not to sow so many of the *Emperor*, namely, *Daniel O'Rourke* one pint, and *Dane Croft Rival* one pint. These two were promised to excel the *Emperor*. The *Bellamy's Green Marrow* I have seen growing, but have never grown it before this year.

Of course, Mr. H. has already satisfied me as to the merits of the *Dane Croft Rival*, and had I seen his statement before I had sown it, I should not have given it even a trial.

Of course, the before-mentioned kinds are intended to form the first crops; were all sown at the same time. It is true, I never have taken notice how many days difference there were at the picking season of the different kinds I might have sown with the *Ringwoods*, but this I remember, being obliged to leave the *Emperor* in its prime to pluck from the *Ringwoods*, as being so very much a better pea.

The time of sowing the earliest crops, for the last twelve or fourteen years, has been, as nearly as possible, about the last day in December, or the first of January, as the weather would permit. We, like others, have had, in bygone days, fine rows of peas up at the above-mentioned time to show our friends; and what could often be said about them by the end of February or by the middle of March! A few March winds, the violent changes from mild to cold weather, the birds, slugs, and mice, left but a few ragged bits of rows, which the gardener was ashamed to be seen sticking, yet must not pull them up, for fear of losing an early dish of peas. As I said before, we always sow our earliest crops in the open quarters (which may be a little screened from the north winds by trees in the back ground) as near as possible to the first of January, having the soil up in good condition, and sown all in the same day.

The rows are measured out as wide apart as the pea grows in height. The peas are sown not sparing the seed at this season. A slight covering of sifted coal-ashes sown along each drill, which is somewhat disagreeable to the slug, &c., then the rows are nicely covered up with a spade or shovel, in the tidest and neatest manner, no labour is spared, and if any doubt exists about the presence of mice, traps are set immediately, never waiting for them to begin the rows of peas first, but we are on the alert for them in time. As soon as the pea begins to make its first appearance through the soil, a string of worsted is strained from end to end of each row, the worsted being strained about six inches above the pea; this is a protection from the birds.

When the peas are all fairly up, advantage of a fine day is frequently taken to stir the earth well up, and among the peas in the rows, and a dusting of quick-lime is frequently applied of a fine evening or morning, as a donation to the

slugs; and on the appearance of severe frost setting in, if the peas are a little above ground, a top-dressing of charcoal dust is sown over the rows. If we have not sufficient of this article, a barrowful of leaf-mould, or the like, is run through a coarse sieve, and sown over the rows. This is done in a tidy, workman-like manner, being strewed along with the hand from a basket. This is not confined to one dose; but these sort of dressings, lime-dustings, earth-stirring, bird's-frightenings, and looking-out for the mice in time; this, mixed-up with thoughtfulness, watchfulness, and feeling a little delighted and determined to have whole rows of early peas for sticking, and although the sticks form a little protection to the pea, as well as supporting them, we always defer this as long as we can, for the purpose of being the better able to keep the earth frequently opened, and attending to the lime-dusting to destroy the slug. Previously to sticking, the earth is well forked-up between the rows, and then, with a spade or shovel, they are nicely and neatly basined-up, without bringing the earth too close up to the stems.

Since we have adopted the early spring sowing, and determined to sow our first crop of peas about the 1st of January into the best prepared soil, and the after-attention, I do not remember a single instance of disappointment; but we have always had the best of crops, and, for ought I know, quite as early as any of our neighbours.

T. WEAVER.

THE SPANISH FOWL, AS RECENTLY EXHIBITED.

THE coasts of the Mediterranean sea have long been noted for the quantity of fowls kept by the inhabitants of those countries; and the traveller, whose observant eye has not disdained to notice their peculiarities, has readily distinguished certain connecting links between them, leading to an inference of their common origin, however manifestly illegitimate might have been their immediate parentage.

These points of resemblance may be concisely stated as a full development of comb and wattles, in both sexes, with a large white ear-lobe, of which colour the face of the bird is seen in a more or less perfect state. Now, the modern fancier has rightly considered that this latter feature, the white face, is not merely highly characteristic of the Spanish breed, but likewise presents the most effective combination of colour. It is required, therefore, that a good specimen should have the whole face, including the ear-lobe, formed of a carmelated pure white skin; to this is added an uniform plumage of glossy black, with a comb rivaling the brightest coral. But, who has ever attempted to breed the Spanish fowl, as described above, without being speedily convinced of the extreme difficulty of retaining the entire white face free from any tinge of red? The most convincing answer to this question would be a reference to the Spanish pens at an exhibition, where, as a general rule, the prizes are awarded to those which are least deficient, rather than to those which are most perfect in this respect. The exceptional cases would be limited to the produce, comparatively speaking, of a very few yards; and where triumphs have been most frequently achieved, the number to be selected from has been an equal element of success with the inherent excellence of the strain.

A larger proportion of first-rate chickens might be extracted from any other race of fowls than we should hope to see from Spanish. We must not, however, be misunderstood as to the purport of these observations. No discouragement is designed to those with whom these beautiful birds have so justly gained favour; but, on the contrary, if their past efforts have not hitherto been so entirely satisfactory as they would have desired, perseverance, based on the recognition of the difficulties, should instigate to further exertions.

But what is the character of the majority of the birds exhibited as Spanish? The face (and this is the point we are now concerned with), and even the pendent ear-lobe, is commonly stained more or less with red, so that the fowls are frequently not to be distinguished from good specimens of what are called "*Minoreas*," which have the ear-lobe, and sometimes even a considerable portion of the face, of a

good clear white. Hence the question so often put in these columns as to the difference between the *Minorea* and the Spanish.

The comb and wattles of the former are as fully developed, their plumage of as rich and refulgent a black, and their form, where attention has been bestowed, is as good; although, perhaps, as their general character, of a somewhat shorter and more compact description, but insufficient in itself to authorise a distinction. Thus, when *Minoreas* are shown in the class for "*any other distinct breed, not as specified above*," their position is not justified by the facts of the case. Close relationship plainly exists, evidenced, moreover, by several other common properties. Adherence, however, to our present system seems to require the definition of the Spanish fowl, after the enumeration of the other needful points, as having the skin of the face, as well as the ear-lobe, of pure, unstained white.

The *Minoreas* are not the only fowls that exhibit traces of family connection with the aristocratic Spanish, properly so called; although, from the similarity of feather, they are those mainly concerned in the matter we have just referred to. The pied and speckled birds known in the Western districts of England as *Anconas*, and the blue *Andalusians*, are manifestly offshoots of the same stock, and being possessed of economical properties fully equal to their white-faced black cousins, deserve, in our opinion, some recognised position on the poultry-list. Competition with these latter is out of the question, lacking, as they all do, more or less, the peculiar characteristic of excellence in the bird to which this name Spanish is now, "*par excellence*," applied. But since, as they are really valuable fowls, might it not be possible to give them the encouragement of a class for "*Spanish fowls of any other variety*," entitling the former as "*White-faced Black Spanish*?" There would be no subtraction from the acknowledged merits of the present exclusive holders of the designation, that would, indeed, of right, be shared by any other fowls of Spanish origin, and that the *Minorea* and *Andalusian* families would thus claim admission, will not be contested. We have no desire whatever to place *Minoreas*, *Anconas*, or *Andalusians*, in competition with the white-faced Spaniard, for they would assuredly suffer by the comparison; but the legitimacy of the latter does not necessarily infer the mongrelism of the former. The quality of the face of the Spanish fowl being all-important in the eye of the judge, other points are not to be less strictly scrutinised; and prize pens have frequently appeared with this feature alone meritorious, while figure and condition have been viewed in too favourable a light. Let us have the white-face, by all means; but this must not be regarded as compensation for the presence of any manifest defect elsewhere.

Although the principal honours of the Spanish pens of 1853 fell to a previous victor, yet it will, we think, be admitted, that the quality of the birds has generally improved; there were fewer decidedly bad pens, and the Judges' labours, therefore, were not so readily performed. Many of the best birds, however, moulted late, and it required every exertion to get those that were intended for Birmingham in proper form before the appointed day for their *debut* in Bingley Hall. Some specimens imported from Spain were there shown, verifying the general opinion that not a single bird of really high merit has recently been obtained from that country. Holland and Belgium, too, have been ransacked for Spanish; but however careful the selection, they still failed in placing their owner's names at the head of the awards.

But the terms of commendation that are so justly due to the birds of this class that have usually taken prizes at the more important exhibitions, must not be extended to many of the provincial meetings, where a most meagre collection of Spanish has usually been present. Judges, it is clear, have again and again been of this opinion, where we read, "first prize withheld; no sufficient merit." And when birds are manifestly deficient in any one important point, we rejoice to see such righteous sentences boldly pronounced, nothing being more injurious than affixing a false value to really bad birds, by assigning them a prize simply from the fact of no competitor of higher merit having then and there entered the lists. The injustice of complaints on such grounds has only been

equalled by the absurdity of the arguments by which these murmurs, loud and deep, also, have been supported. An unfortunate bystander is forcibly carried off to some scarlet-visaged pen, and told how unfair the decision that refused them a prize—"Bred from _____'s best birds, I assure you; cost _____; therefore, is it not clear that I ought to have won with them?" If the conclusion is not always so plainly uttered, nine times out of ten it is uppermost in the mind. Talk to them of an imperfect face, bad condition, foul feathers, malformation of the comb, or any other blemish, however apparent, the fact of their descent alone is still regarded as the one important point for consideration. If twelve eggs are purchased, it seems to be thought a most unluckily mischance if twelve first-rate chickens are not produced and reared. What has been already said as to the patience requisite for the production of prize Spanish, would assuredly save much disappointment in this respect.

There has been more than one instance, of late, where Nature is thought to have done her work so imperfectly that art is called in to complete it. We allude, especially, to such Spanish birds as have a good face, but the line of feather above the eye is thick and continuous. This defect has suggested various operations by the tweezers, and even the razor would seem to have been thus employed. Such practices, we need hardly say, are readily detected, and are most justly punished by the immediate disqualification of the birds thus tampered with. If the face has become anyways dirty, washing with cold water is all that is needed, and anything beyond this is far more likely to do harm than good.

A dark, heavy line of feather between the eye and the base of the comb certainly mars the effect of a good face, and the breeder should seek to get rid of it, though by means less objectionable than those just referred to. Many a bird otherwise good in face is thus disfigured; for we know not if we could lay our hand on a single specimen without one feather on this part. But with the example before us of what has already been effected by Spanish breeders within the last few years, we are certainly justified in looking forward to improvement in this particular.

The Spanish chicken classes frequently require more careful treatment at the judge's hands than their seniors; the latter, in a mature state, stand or fall according to their present form; while the former, pullets more particularly, would petition for some prospective consideration. And this, stern advocates as we have ever been for judging all birds "*as they are*," we think them entitled to. The difficulty is to read their present looks aright.

Poultry books abound with recommendations of the Spanish fowls to the inhabitants of cities and large towns, alleging their sable plumage as an imperceptible recipient of dirt and smoke. From the condition of many pens, we must suppose that this advice has been very extensively acted on, and that they had thus supplanted the very perker in the possession of his sty. But the refulgent character of the bird's plumage soon vanished under such unfair treatment, and no denizen of our yard does greater credit to the enjoyment of a good healthy run.

A pen or two of *White Spanish* are occasionally exhibited, but, like the parsnip that was described as a "*sick carrot*," they are poor, meagre-looking birds, destitute of all the charms that commend the black Spaniard to our notice. Many of these are, probably, "*albinos*," like the white birds bred by black Polands, and, consequently, of the same constitutional weakness. But others that now present themselves in a white garb may have once been differently clothed, for a strong family link between the various fowls that have been spoken of as of Spanish origin is the extensive metamorphosis that they are apt to undergo during the process of moulting. Spanish, Minorcas, and Anconas, have continually come to our notice under such circumstances, and the Andalusian, we are told, is no exception to the rule. The black becomes a mottled, and, sometimes, though rarely, even a perfectly white bird, and subsequent moults have, at times, restored the bird to its former garb, while in other instances the change has been permanent.

There is every reason for believing that the Spanish classes for the coming season will bring out numerous competitors, and thus, wherever the honours may fall, the victory will be proportionately more glorious. As to the

adult classes, the exhibitions even past will afford a tolerably clear indication of the names that are likely to appear as winners, saving always the case of newly-imported birds. The chickens, however, from the immense numbers of eggs and birds that have now been distributed, forbid any such anticipations, but in both one and the other we are sanguine as to the breed retaining its present high position.

SUGGESTIONS FROM THE GARDEN AND THE FIELD.

By *Cuthbert W. Johnson, Esq., F.R.S.*

ORGANIC CHEMISTRY, AS ILLUSTRATING THE WISDOM AND BENEFICENCE OF THE CREATOR.

THERE are certain trains of thought into which we are all pretty sure to be led by the scenes in which we are placed. Our curiosity is excited, our attention directed to the phenomena around us. We naturally become desirous of information, and are insensibly led towards that point at which our knowledge ceases. No person sees more of such inviting objects of inquiry than the farmer and the gardener. They daily witness mysteries upon mysteries, all full of interest, which the chemist aids them to only partially understand. Let us accompany an intelligent cultivator around his fields, and when we are partaking of his pleasures in the inquiry after knowledge, let us store with him a few of the wholesome reflections which may present themselves during our walk.

A very early impression will suggest itself as we commence our observations, that from the moment that God ordained that man should be formed in his own image, should have breathed into him the breath of life, from that moment commenced, in his case, a series of chemical phenomena, all made subservient to his comfort and to his happiness; in which the wisdom of the design is only equalled by the beneficence with which it is realized. In furtherance of the object of this essay, let us merely glance at these mighty arrangements. In a single great instance or two, let us consider only some small portion of the chemistry displayed in the formation of our bodies, our breathing, and our food; and in so doing, let us not attempt to exhaust the subject by closeness of analysis foreign to the objects of this little sketch, but rather let us adhere to those more prominent, and easily understood, facts, which every plainly educated person most readily understands.

The creation of animal life was preceded by certain preparatory events, which laid, as it were, the great foundation for those which so speedily followed in their train. The pasture was first prepared—the banquet was already spread on the earth's surface—food was created for other organised beings before animal life first tenanted the globe—the wants of animals were foreseen, their comforts attended to by the omniscience of Omnipotence in a manner which demonstrated, at the very commencement, His care for their future welfare, His regard for their happiness.

Vegetables were the first created of all organic substances (Gen. i. 11); the creation of plants preceded that of animal life, and as it would seem almost of necessity, since they were destined to be the food on which the animal tribes were alone to subsist. The sacred historian, therefore, as soon as he has described, in his sublime language, the creation of heaven and the earth, and of light, and the separation of the earth from the water, next tells us that God ordained that the earth should bring forth *tender* grass, the herb yielding seed, and the fruit-tree yielding fruit. This was the first grand step towards the creation of animal life; it was the preparation of the pasture in which a still more perfect class of organized beings were to dwell; and these, too, under every imaginable form and variety, and in countless profusion. Every leaf was intended to contain its animalcule, every blade of grass its tenants. On these leaves, and on these grasses, the superior classes of animals were to feed, to rest when weary, and to seek in ill health for the cure of their diseases.

It was necessary, therefore, to adapt the chemical composition of these grasses to the digestive powers of the animals, which were immediately afterwards created, and

which were to subsist upon them. It is evident, that if they had been formed devoid of the sugar, the oil, the fat, the starch, the vegetable albumen, and other nutritious matters in which they all abound; if, for instance, they had been composed entirely of earths or metals, that then these could not have served as the food of animals. This is not entirely an imaginary case; only consider those plants in which the earth Silica in unusual proportions abounds, and note how nearly devoid of nutrition they are. Take the *straw* of Wheat for an example, in which it is found in considerable proportions (while it is absent entirely from the *seed*); or the Dutch Rush, in which it exists in still greater abundance. In these, it is true, the Silica is fulfilling a very useful purpose, by imparting to the stems the requisite degree of hardness and strength to support the seeds; but how nearly devoid of *nourishment* they are, every poor beast wintering in a straw-yard by his very appearance indicates.

The marvellous difference between the chemical composition of the seed of the Wheat, and the straw which supports it, can only be explained in one way—by the contrivance and the beneficence of the Deity. It is idle to say that it is all the offspring of chance; chance never yet accomplished anything so remarkable as even the formation of a common piece of mechanism. No one ever regards the possibility of the chance formation of a water-mill, or a steam-engine, even if eternity is imagined as allotted for the operation; and yet the contrivance and the wisdom displayed in the construction of these machines is just nothing when compared with the operations going on in a vegetating plant of Wheat.

The chemist detects many of these, even to him, mystic operations, by the examination of vegetable chemistry. He finds in the flour of the Wheat only three or four substances, such as carbon, hydrogen, oxygen, and nitrogen, so that there is little reason to complain of the number of the ingredients; but how these three or four substances are united together, so as to form vegetable substances, he cannot, by any chemical reasoning, explain. He sees that the union is accomplished, that the gluten and the starch of the Wheat are produced with unvaried regularity, but it is a process far beyond his powers of imitation. It is true, he can readily decompose them, and separate the elements of which they are formed, but it is in vain that he attempts to recombine those elements, so as to form the animal or vegetable substance in which they previously existed. Those marvellous combinations are the works of a Divine Author, and of Him alone.

(To be continued.)

DORKINGS, AS RECENTLY EXHIBITED.

THE writer of the article in your last number, under the above heading, is so conversant with his subject, and the whole article is so well written, it is the more necessary that some stricture should be placed on points in which he appears to be in error. The observations on comb and colour are so correct, and well stated, they cannot fail to produce benefit, and will, it is to be hoped, have an effect beyond their apparent intention of giving a helping hand to the judges in their decisions; aiding their well known desire to cast to the winds all priority arising from these accidental appendages. If the great object we have in view be the improvement of the various breeds "of domestic poultry," it should clearly be our desire (especially in this class of the "Farmers' Fowl") to induce every exhibitor to bring before the public, as "Models," the best birds in his possession. But under the present system of *practically* requiring, in the same pen, hens and pullets of the same comb and colour. (good matches as the phrase goes), I appeal to the experience of every exhibitor of any note, whether for the sake of this object he does not frequently leave at home, not merely his *second* best, but frequently sends his sixth, or it may be, his tenth best bird for the sake of effecting the "match." Nor does the evil rest here. Young Amateurs are constantly applying to eminent breeders to supply them with fowls, and either fail in their object altogether, or obtain a disparity in quality, because, following the error of the exhibitions, they are content only to secure "good

matches!" Now, as sisters of the same clutch frequently vie with each other in all points of excellence, and differ only in those of comb and colour (a fact acknowledged by good breeders), I ask, whether it is not desirable to discard these contingent and imaginary qualifications?

With respect to weights, also, the writer correctly observes, that vast improvement has been made in the last year without the sacrifice of symmetry. But he must permit me to consider him greatly in error, and unwittingly misleading the public, in stating that "ten pound cockerels, and eight pound pullets have been no uncommon productions in the exhibitions of the last year." That such Dorkings have been exhibited, I can myself testify; but it is far from the fact that they have been common. And there is this important consideration attached to the error, that Tyros applying to prize winners for fowls, feel disappointed, and, perhaps, something more, in finding the birds sent fall far short of the standard stated to be "*common*," on such good authority. Let any one doubting the above appeal to that best of judges, Mr. Baily, and the writer will readily succumb to his decision.

There is one other mistake to which I must also allude in reference the Reigate Show. That the limitation of this Exhibition to the three adjoining counties was an error, is admitted by the gentlemen who took the active part in its formation and management, and will be rectified for the future. But how far the "*limitation tarnished the laurels that were there won*," may be decided by the following facts. All the first prizes in the Dorking class were taken by a clergyman in Kent; and the same fowls, in the same month, took all the first prizes at Hitchin, where one pen of chickens was claimed for fifty guineas; and the same fowls were exhibited at the Metropolitan, in January, and there again earned the first three prizes. In classes five and eight, by the Rev. J. Boys, the exhibitor on the two former occasions; in class six, by Mr. Smith, the gentleman who claimed these birds at Hitchin. As these are the only occasions in which these fowls have been exhibited, I confidently appeal to the candour of the writer of the article in your last number, whether they have not amply redeemed the laurels which the limitation is said to have tarnished."

[In reference to the above remarks we readily admit, that if the expression of an opinion that "cockerels of 10 lbs., and pullets of 8 lbs., have been no uncommon productions," could be construed as equivalent to an assertion that such specimens were *common* objects of every day experience, the statement would be inaccurate. The sentence in question, however, merely implies that birds of these weights have been shown on several occasions, and, consequently, that they may justly be held forth as models for the breeder's imitation, although a degree of skill and judgment beyond that of the novice will certainly be found requisite for the attainment of this result.

The allusion to laurels won at Reigate being tarnished by the limitation of exhibitors at that show to inhabitants of the adjoining counties, refers simply to the credit of the prizes there gained. No disparagement whatever of the birds themselves was thereby designed, nor any inference conveyed as to their appearance, favourable or otherwise, at any other exhibition. It will hardly be questioned but that a premium, even with unrestricted competition, reflects higher honours than the championship of a single district.—Ed.]

VEGETABLES AND FRUIT OBTAINABLE IN MARCH.

THERE is so little to be got in addition to those mentioned for last month (p. 365), that it seems a waste of time and space to repeat them. Many things, such as Cucumbers, Beans, Strawberries, &c., will just be getting more plentiful. I hope the sanguine will keep the preliminary remarks in that page in mind. I shall mention one or two matters to which my attention has been directed.

1. **BLANCHED TURNIP TOPS.**—I have had these in use for a number of years. I did not, however, invent the dish, but saw it mentioned as a good one, if I mistake not, in an almanack published by the proprietors of the "Illustrated News." Most people relish turnip tops when in a green state after they begin to grow in spring, and that is just the

time when it would be useless to attempt to blanch them, as the top would rise too quickly, be apt to be stringy, and on the whole not so good as the green-growing top out-of-doors. In winter they are preferred by many even to Sea-kale. Darkness, and a heat from 50° to 55°, produce them in great perfection, such as in a slight dark hotbed, a mushroom-house, &c. Nothing more is required than to get the turnips from the field, with the top uncut, and when stuck among soil or litter the head will soon push, and should be cut when about six inches long. A second or third crop may be taken, but the first is always the strongest and best. Besides, if long cut, the turnips are robbed of their nourishment, but if cut only once, the turnip is little more injured than it would be in the field by the end of March or the beginning of April. I have tried various kinds, but all others are either bitter or insipid, except Swedes. Their blanched tops, as a winter dish, are really delicious.

2. BLACK PRINCE STRAWBERRY.—I mentioned, in an article, last autumn, how well this did for a late crop out-of-doors; how scarce I was of it for an early crop; and how I shifted some, potted them, plunged them in a little heat, keeping the tops cool, hoping that thus time might be gained, and that these plants might be induced to bear an early crop. In this I have, to a certain extent, been disappointed. My *Keen's Seedling*, potted early in small 48's, have beat them hollow. I intend, therefore, to give them a fairer chance next season, by early potting, as that I have long found to be the great essential, along with early maturing of the bud, for early forcing. Besides being less fruitful with me than *Keen's Seedling*, they seemed more tender, and more liable to insects. All this I mostly attribute to their late potting, and mean to give it another limited trial, as some of my friends have had good crops since the new year. I mention this chiefly to show that no doctoring of the plants in autumn will compensate for the want of early potting and early maturation of the buds. At this season, and onwards, plants will do pretty well when lifted and potted, and put with or without pots into moderate hotbeds. The extra heat, in these cases, should, for the first ten days, tell chiefly on the roots, by allowing a stream of air to pass over the tops. On the whole, though I value the *Prince*, unless for an early crop, I would never think of substituting it for *Keen's Seedling*.

3. TOBACCO.—Thanks to sulphur fumigations, these Strawberries are the chief thing on which an insect presented itself. I sent for some strong shag, and they sent me what I believe they call *bird's eye*, and it seems to be pretty well "all in my eye," as far as the fat flies are concerned, as they look just about as stupidly comfortable next day as a man who has half smoked himself blind. Now, if two smokings, at most, will not make them all tumble from their perch, a person would extirpate them cheaper by using his fingers and soot and lime-water from a syringe. I cannot say I have been thoroughly satisfied with any substitutes for tobacco. The question, however, is well worth a friendly ventilation; first, as to the materials that have been successfully used as substitutes; and, secondly, as to the best and cheapest tobacco for the purpose, and where that is to be conveniently obtained; a hint not unworthy the tobacco manufacturer, as an article that would quickly destroy insects, and not hurt the plants, would meet a most extended sale; what is sold as shag in the grocer's or tobacconist's retail shops being so different in its quality. All beginners should use it rather weak at first.

CAULIFLOWER.—This was mentioned last month, but it and *Snow's Brocoli* will now be getting on the wane. The latter is one of the best helps the gardener ever had. Sown in March and April it will produce beautiful, white, firm heads from the end of October. The frost came upon me sooner than I expected, and I covered it up where growing with litter and refuse hay, and I have had a good supply to the present time.

5. RHUBARD AND SEA-KALE.—Where there are no means of forcing these out-of-doors they may easily be forwarded by taking the roots up and placing them in soil in any dark place, with a temperature ranging from 50° to 60°; and these roots, cut to pieces and planted out in April or May, will be fit to force again in the second season. R. FISH.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.—DEC. 1853.

The following donations were announced:—

1. Seeds of the 'Cabbage oil,' and blue dye plants of the Chinese, and seeds of four varieties of Melons. Presented by Mr. R. Fortune.

The following is extract of Mr. Fortune's letter respecting the above seeds:—

"The *Cabbage oil plant* forms one of the staple productions in the Provinces of Chekiang and Keang Soo during the winter and spring months, and is highly valued by the Chinese. I believe the Chinese kind is considered more productive than any of our European varieties, and it is possible it may be better than those at present cultivated in India. At all events, I send it round for trial, and venture to suggest its being sent to a district where oil of this kind is produced. The "*Tein Ching*" (*Isatis indigotica*) is the plant which produces the Shanghai liquid Indigo, a substance largely used in this part of China, where blue cotton cloth is in great demand amongst the masses of the people. The four varieties of *melon* are also sent for experiment. They are valuable in China, not so much on account of their flavour as their productiveness, and they grow luxuriantly without that care which it is necessary to bestow upon English melons introduced to this country. In the summer months the markets are abundantly supplied with these fruits, which are, in fact, the apples of the country, and are eaten by the natives much in the same way as we see apples in country towns at home."

The following communications are also submitted.—

1. From W. G. Young, Esq., Under Secretary to the Government of Bengal, furnishing extract of a letter from Mr. R. Fortune, dated 18th July, seeking more precise information regarding the Chinese green vegetable dye, to which the attention of the Society was called by Mr. Henley, in March last.

2. From R. Fortune, Esq., dated Chusan, 18th July, on the subject of obtaining seeds, plants, &c., for the Society.

With reference to the above two communications, it was agreed, on the recommendation of the Council, that a copy of M. Persoz's Memoir, published in '*Les Comptes Rendus*,' sitting of the 8th October, 1852—on the green vegetable dye of the Chinese, be forwarded to the Government of Bengal for Mr. Fortune's information. Further, that the sum of £50 be placed at Mr. Fortune's disposal, to enable him to meet all expences, export freight, connected with the Society's requisitions for plants, seeds, &c., and that the P and O Company be solicited, as a special case, to forward such boxes of plants as Mr. Fortune may send from Shanghai free of freight to the Society.

DOMESTIC ECONOMY.

THERE is a great want, at the present time, of good publications relative to "common things." Lord Ashburton and others are most wisely making an effort to have a knowledge generally diffused of those "things," for they include all that is useful in our every-day life. That effort is much impeded by the want of appropriate publications, and we, therefore, are glad to meet with one which is quite suitable to the purpose. It is written by Mr. Tegetmeier, so favourably known by his communications to our columns, and is entitled *A Manual of Domestic Economy: with Hints on Domestic Medicine and Surgery*. It is very small, very cheap, and very sensibly written; indeed, it may be fairly characterised as being common sense applied to common things. The following extract from it is a fair specimen, and is especially deserving of general circulation at this time of dearth:

"WHEAT AND ITS PREPARATIONS.—The variety of wheat chiefly cultivated in Great Britain is that termed *Lammas* or winter wheat, being usually sown in September or October. Spring wheat, so named because it is sown at that season, is less productive.

"Wheat is one of the most nutritious of the corn plants; before being ground, the grain contains from twenty to thirty per cent. of nutritive substances, chiefly gluten. When ground into fine flour, it is not so nutritious, as a

large proportion of the most nourishing substances resides in, and is removed with, the bran, pollard, and middlings.

"Coarse flour contains all the most important substances required to support life, namely, nutritive food in the gluten, warmth-giving in the starch, an abundance of fat and oil, and a high proportion of bone-making and nutritive materials, in the pollard and bran; it follows, therefore, that brown bread, which contains a proportion of bran, &c., is a much more valuable food than that made from the finer flour, from which these substances have been entirely extracted.

"*Bread.*—Good bread should be made of wheaten meal, or flour, water, salt, yeast, and a small quantity of potatoes. Baker's bread frequently contains also a quantity of alum; this is added for the purpose of enabling inferior flour to be used; it renders the bread whiter, firmer, and less crumbly when cut. The employment of this powerful astringent, however, is decidedly injurious, and aperient medicines are often requisite to counteract, in some degree, its evil effects.

"Flour, when mixed with water and yeast, and allowed to stand, undergoes a process called fermentation, and a portion of gas is thus generated. This gas, owing to the tough glutinous character of the dough is not able to escape, and it causes the latter to swell, and assume a spongy character, which greatly contributes to the digestibility and excellence of the bread.

"In preparing home-made bread, the usual plan is to mix the materials together, and allow the fermentation to proceed for about four hours before putting the dough in the oven. Bakers, however, adopt a very different course; they mix a small portion of the flour with yeast, and set it to ferment for some hours previous to making the mass of dough; this they term "setting the sponge," and it is doubtless the best plan when a large quantity of bread is required. Good bread is of so much importance in a family, that the writer has taken some pains to procure the best receipt, and he has to express his obligations to Mr. Duer, of Bond-street, for the following directions, which, when strictly followed, he can state from experience, furnish bread greatly superior to that ordinarily made in private families.

"*To make a Half-peck Loaf.*—Take three-quarters-of-a-pound of well-boiled mealy potatoes, and mash them through a fine cullender or coarse sieve, add to them one-eighth-of-a-pint of yeast (about two table-spoonfuls), and one pint and three-quarters of lukewarm water (88° F), together with about a-quarter-of-a-pound of flour, to render the mixture the consistence of a thin batter; this mixture should be set aside in a warm place for six or eight hours in order to ferment, at the end of which time, it will be found (if it has been warmly and closely covered over,) to have risen considerably, and to resemble yeast in appearance, except in colour. The sponge so made is then to be mixed with one pint of water nearly blood-warm (viz., 92° F.), and poured into the half-peck of flour, which has previously had one ounce-and-a-quarter of salt mixed with it, and kneaded into dough, which should be allowed to rise in a warm place for three or four hours before baking. After the dough has risen, it should be handled as little and lightly as possible whilst it is made up into loaves.

"In some cases it will be found convenient to set the sponge over-night, and make the dough very early in the morning; or the sponge may be set very early, and by keeping it and the dough rather warm, the loaves will be ready for baking in the afternoon.

"In the writer's family, bread made according to these directions is found to bake admirably in 'The Cottager's Stove': the only caution required is to turn the loaves upside down when nearly done, to brown the under crust.

"Bread should never be eaten until it is twenty-four hours old. When taken sooner it cannot be masticated properly; it is therefore swallowed in doughy masses, extremely difficult of digestion.

"Some few years since, unfermented bread, in which the place of yeast was supplied by carbonate of soda and muriatic acid, was extensively tried, but the nicety of manipulation required, and the great attention necessary in weighing and measuring, renders the plan unfitted for general use; with care, however, it is capable of furnishing an exceedingly palatable and wholesome bread. At the present time, various bread powders and patent flours are

sold, capable of making light bread by the addition of water only; they contain, however, chemical substances which remain in the bread, and impart to it medicinal, or in some cases even injurious, properties.

"The only chemical substance capable of being used without any injurious effect in making bread is the carbonate of ammonia. This is largely employed in light biscuits, &c. It is converted into vapour by the heat employed in baking, and renders the biscuits very light, whilst it is itself entirely carried off during the process.

"All cakes which contain, in addition to the ingredients used for bread, fatty materials, as butter, lard, or dripping, are most indigestible, and unfit for children or persons with weak digestion. It should always be remembered that fat, when heated with flour, forms a compound which is acted upon by the digestive fluid slowly and with difficulty; hence most kinds of pastry, as pies and ordinary puddings made with flour and suet, are not suited to children or invalids. Biscuits containing butter are open also to the same objection.

"The following directions for making a perfectly unobjectionable pudding for persons recovering from illness are extracted from Dr. A. Thomson's "Domestic Management of the Sick Room," a valuable work for all whose duties call them to the care of invalids:—

"Grate half-a-pound of stale bread, pour over it a pint of hot milk, and leave the mixture to soak for an hour in a covered basin, just large enough to hold it, tie it over with a cloth, and boil it for half-an-hour." Sugar, and a little thin paring of lemon peel, may be added to give a pleasant flavour."

AMERICAN NOTES.

It appears, from the following statement taken from the *Zanesville Gazette*, that the wheat crop of Ohio is annually diminishing. The yield was

	Bushels.
Wheat crop of 1850.....	35,000,000
Wheat crop of 1851.....	25,000,000
Wheat crop of 1852.....	25,000,000
Wheat crop of 1853.....	22,000,000

Four years' crop..... 107,000,000
Average crop of four years..... 26,750,000

At the New Hampshire State Fair, Gen. Riddle, of Bedford, exhibited two horses, one 26 and the other 28 years old. The old fellows plowed their eighth-of-an-acre in nineteen minutes, without rider, line, or whip. They have been kept for several years on a daily allowance to each of three pounds of cut hay mixed with three quarts of Indian meal and moistened.

The Short horn Bull, *Fourth Duke of York*, purchased a few months ago at the Earl of Ducie's sale, by Gen. Cadwalader, of Philadelphia and Geo. Vail, of Troy, N. Y., for *five hundred guineas*, died on board the Ship, Queen of England, on the passage between Liverpool and New York.

The friends of Dr. Ward, of Cincinnati, and, indeed, all the friends of Horticultural science, will be pleased to learn that he has so far recovered his health as to be able to resume his labours as the principal editor of the *Review*.—He will be assisted by Mr. Ward, and the *Review* will doubtless deserve, as it has heretofore done, the support of every friend of Western Horticulture and rural arts.

One of our exchanges thus describes a corn stock harvester recently invented:—"Between two wheels there is an axle, to each end of which is attached a knife for cutting each row of corn. To the axle is also attached shafts for the horse which pulls the machine.—The horse walks between the rows of corn, and the knife just inside of each wheel cuts the corn, which falls on a bed to catch it, in a manner resembling the operations of a wheat reaper. The bed which catches the corn, opens to the centre at the pleasure of the operator to discharge the corn in bundles. We are informed, that with one man and a horse the machine will cut 20 acres of corn per day. It is the invention of a citizen of Illinois."

Mr. C. A. Chapman, in giving an account in the *Michigan*

Farmer, of the productions and profit of Broom corn says:—"I raised this year a piece on forty-eight rods of ground. After cleaning off the seed, I had so large a pile I thought I would measure it.—I had twenty-five bushels rounding measure; a little over a half-bushel to the square rod, or about eighty-five bushels to the acre. I need not say the land was rich to produce such a crop; but it was not cultivated as it should have been. It was planted in drills, and the cultivator passed through it once, and then I went through with a hoe and thinned it out, but it was left too thick, so that there were many small heads. The seed is excellent to feed sheep and lambs, and poultry, whole; but for all other feeding it should be ground. It is heavier than oats, and I think worth more per bushel when ground."
—*Iowa Farmer and Horticulturist.*

THE SHANGHAI FOWL.

It is unjust to deny that they possess individual points of great beauty, even if the "*tout ensemble*" be not so symmetrical or so attractive as that presented by the Game fowl. Their most inveterate opponents must admit that the head of a good Cochin fowl is handsome—that in the face-expression of the pullet, especially, there is much beauty, and also a *loving tenderness* and an intelligence not observed in other poultry, which make them especial pets with those who rear them. There were grace, symmetry, and majesty, in the birds belonging to Mr. Harrison, of Snelston, which took the first prize at Derby, and which, indeed, made them appear to belong to a different race of birds from those long-legged, bony, shapeless, distorted, things which generally pass under the name of Cochin-China fowls. Not every cow with short horns can be fairly considered as a type of those beautiful and useful animals which, emanating from the meadows and byres of Charles Collings, in Durham, have spread themselves over the kingdom under the appellation of "short horns;" nor should every mongrel fowl with long legs, short tails, and ugly bodies, be considered as the representatives of the Shanghai fowls of Sturgeon, Punchard, Herbert, and Fairlie. Honored names these! who have kept the field against all comers, for bull, partridge, white, and black Cochin's respectively. Not but that in some stray combat they have been beaten, as Staunton in a solitary game of chess, or Pilch in a single inning at cricket, but in a season's campaign they are ever victorious, and public acclaim awards to them a place in *Poultry* annals as high and as honored as those occupied in the "*Herd Book*" by Collings, Bates, and Ducie. But to return from the breeders to the breed. Let the best specimens of each variety be considered in a review of their respective merits, and it will be found that they are not destitute of beauty. The "buffs," perhaps, are more adapted to the quiet, sober taste of English people, to that peculiar sense of the beautiful which regards an entire suit of black as the appropriate and graceful dress of a gentleman, and denounces variety or colour in costume as vulgar and "unbecoming." Hence the popularity of these said "buffs" or Sturgeonite Cochins; but the Partridge ones, in perfection, are not to be despised. The white variety (if variety be strictly applicable to birds which cannot be depended upon for continuing their characteristics in their offspring) is very handsome, when obtained of good form and colour, like the fowls from Mrs. Horbert's, of Powick. They possess deep red combs and wattles; and with these, beaks and legs which rival the golden splendour of those of the Blackbird. These red combs and golden legs contrast beautifully with their milk-white plumage. Upon a grass lawn, stretching out in front of some old mansion, like Haddon, or Hardwicke, they look very attractive, and with Peacocks, and golden-pencilled Hamburgs, form a group fit for the inspection of Majesty, and would have fascinated the pencil and the brush of that immortal poultry painter with the hard name, Hondekæter.

However, utility should precede beauty; and in the estimation of the British Farmer, "handsome is that handsome does;" and here the Shanghai fowl will not be found wanting. As I have said before, they are *excellent* layers, and arrive at maturity earlier than any other large-sized fowl. By the term "maturity," I mean the age at which a bird

will commence laying eggs, and thus perpetuate its race. They will, moreover, prove *hardier* than any other fowl, except the Game breed; at least my experience supports this assertion. In a very elevated position, with the thermometer for many days at 12 or 14 degrees below the freezing point, and during the night of January the 3rd, three degrees below zero, six Cochin fowls, five Spanish, eight Dorkings, and four Golden-pencilled Hamburgs, had to brave the cold, with no further protection than that afforded by a common poultry shed, without artificial warmth. Upon the first, the cold left no appreciable mark; the Spanish were sadly "mauled," the combs of all of them shrinking into small dimensions, and becoming as black as a choked cobbler; the Dorkings also suffered slightly (with one exception); the only parties escaping scatheless being the Cochins and the Hamburg fowls. Of these two, the birds from the Celestial Empire had the advantage, for they laid eggs almost daily, while their pretty companions postponed this duty until the mercurial tube of the thermometer should attain a more respectable position in society. When this has been achieved, they will, doubtless, again resume their cackle, or, to use the fine language of our apothecary, they "will express themselves in the natural language of philoprogenitiveness."

And now, what are the *points* which a good Cochin-China cock should possess? It should be of large size—an adult bird of two years old ought to weigh at least ten pounds—it should have a round head, short, thick neck, a broad back, and strong shanks, wide apart—the shanks and legs and outward toe should be well-covered with feathers, and the toes should be four in number, the middle one being much longer than all others. The eye should be large, reddish in colour, and expressive. His feathers should be abundant—the saddle feathers large, and flowing gracefully downwards to the ostrich-like tail. The comb should be upright, indented, and projecting backwards; the hinder parts of the birds should have a square appearance from a mass of soft "fluffy feathers." The faults to be guarded against are those which approximate the fowl to the Malay, that is, a long face, long, *clear* shanks, and *close-fitting* feathers; or to the Dorking, by a *fifth* toe destitute of feathers. The early-imported birds were many of them crossed by these fowls, and the stain will frequently show itself even in the third generation. The Amateur demands a *uniform* colour in the Buff, free from white or mealy spots, and similar unity in the black and white varieties. Practical farmers can afford to smile at these niceties—and look to form, quality, and substance as preferable things. If a fowl, like a Dutchman's tulip, were a thing *merely* to look at, these fancies might be very well; but so long as the essential characteristics of this breed be guaranteed by *shape* and *size*, it will suit both the farmer's pocket and his future success to wink at a "dark hackle," or a "mealy wing."
Terybam sat sapientibus—which our clergyman tells me is the Latin for the wise saying, that a nod is as good as a wink to a blind man.—(A DERBYSHIRE YEOMAN, in the *Derby Reporter*.)

GREAT MORTALITY AMONG BEES.

I STATED, in my communication to you, last summer, that the honey season ceased on the 18th of June in this district; I will now inform other apiarists of my fate. My stock, last year, consisted of eighteen hives, four of which swarmed, so that at the end of the season I had twenty-two hives. Three out of the four swarms died early in the autumn, and to-day I have discovered that fourteen more are dead, in many of which there is plenty of honey, but only a few dead bees. The continued damp and foggy weather, in November and December, succeeded by intense frost, seems to have acted most injuriously, for many of the combs were covered with mould. Some of the hives were in bee-houses open to the south, others on stands facing east, and all protected by bee-pots, with a quantity of tow under them, to keep the hives warm. Perhaps some of your apiarist correspondents who may, or may not, be similarly situated, can give me some information, why and wherefore the great mortality.—A COUNTRY RECTOR, *Tadcaster*.

TO CORRESPONDENTS.

. We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of The Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

ROOT-CROPS ON HEAVY SOIL (*A Subscriber from the Beginning*).—Your strong land, if it has been fallowed, and submitted to the effect of frost during the past winter, should not now be ploughed any more this season for root-crops, but worked with the scarifier as often as the weeds make their appearance; by this culture you will retain the kind, mellow surface which the frost has given you. All the root-crops on this soil will do best drilled upon the flat, with artificial manures applied; and in case you have a quantity of charcoal saturated with liquid-manure, or night-soil and ashes, or soot, or, indeed, any of these useful fertilizers, let them be used with, and in addition to, the usual quantities or kinds of artificial manures now in use. Mangold Wurtzel of the *Orange Globe* variety is the best for your soil; and the manure to be applied by the drill should be two cwt. of superphosphate, with an admixture of a liberal quantity of any of the above-named fertilizers; but before drilling these, harrow in and sow broadcast two or three cwt. of Peruvian guano per acre, according to the state and condition of the land; also, at any after-period, if the plants do not look prosperous, sow over them two cwt. of guano just before rain may be expected, using the hand or horse-hoes to connect it with the soil. Upon your land sow *Skirving's Improved Swedes*, drill upon the flat, and manure with two cwt. of superphosphate, three cwt. of bone-dust per acre, and also a good allowance of the before-named fertilizers. Guano will not answer for this crop upon your soil, because the roots would be liable to decay in the winter months. If the Common Turnips required are for early feeding, you cannot do better than use the seed of the *White* or *Red Tankard* variety, to be manured and managed in the same manner as recommended for the Swedish Turnip. These remarks are made at the request of "A Subscriber from the Beginning;" but all these subjects will be found treated of in detail in different back numbers of THE COTTAGE GARDENER, at their respective seasons or periods; we must, therefore, for further and full information upon this subject, refer to the articles in question, which have appeared in due course of the year 1853.—J. B.

RHODODENDRON-RED (*J. O. W.*).—A hed of them seven feet high, and five feet of that "like walking-sticks," may as well be left as it is till the top flowers; at all events, the second week in May is about the best time to cut such Rhododendrons. Six weeks before that, or say by the first of April, all the smaller shoots, below five feet, ought to be cut to four, five, and six inches from the older stems. The buds on these short stumps will be getting so forward that they will start with buds on the stronger branches on equal terms. See this more explained to-day in any other page. In May, cut the strong branches at different lengths, from five feet to eighteen inches.

BUDDING ROSES (*Ibid.*).—All the Perpetuals ought to be budded in the last fortnight in June, in order to grow and make some progress before frost. All the summer Roses will do from the middle of July to the end of August. *Hybrid Perpetuals should never be budded between the 10th of July and the 20th of August*, but they are safe enough as soon before that and as late after that as buds can be had and the bark moves freely. The wild shoots should not be shortened at the time of budding, nor until September, and even then it depends on the sorts and the forwardness of the buds. Shoots budded in June should be stopped to half their length in about a month.

VINES IN A GREENHOUSE (*Ibid.*).—As they have been so long under greenhouse treatment, you may begin to force them now by closing the house early in the afternoon, and as long as the glass keeps above 45°. You need not use fire-heat till the last day in March. All through April keep the fire-heat from 50° to 60°. Next year you may begin forcing by the last week in February, and after that at the beginning of the new year. If you find the least difficulty in forcing the Grapes, the middle of January will be your best time to begin, and then not to use fire-heat above 50°, for the first six weeks, nor let the house cool below 45°, unless the weather is very cold indeed, when about 40°, early in the morning, before the leaves come, would not be too cold. There is always more danger from too much than too little heat in first forcing of Vines and all fruit-trees.

COATING FOR HOT-WATER TANK (*J. M.*).—You have a hot-water wooden tank, and have used pitch and coal-ash to coat the inside, but find the hot-water melts it. You wish to know what material will cause the tank to be water tight. We know of none, excepting you try Roman cement, and if that does not answer, then coat it with zinc; or, perhaps, it will be the cheapest and best to adopt the latter material at once.

GOLDEN-SPANGLED COCK (*A Subscriber*).—Mr. Tegetmeier's paper on the 2nd of February does not at all refer to "Hen-feathered Golden-spangled Cocks," but to a well-known phenomenon of pullets of any breed that are barren assuming the gait, crow, &c., of the cock.

MIMULUSES AND PETUNIAS (*Ibid.*).—Your best Mimuluses are No. 1, 5, 7, and 9. You should procure *Rubini*, and *Beauty of Scarb'ro'*. Your best *Petunias* are your No. 2, 5, 6, 9, 12, 15, and 17. *Beauty Supreme*, is a light lilac; *Beaute de Moulins*, rose; *Incomparable dark*; *Prince Arthur*, purple; *Lady Callum* and *Triumph*, striped. The rest are unknown. The best *Calceolarias* to grow near London, are your No. 1, 3, 5, and 7. Your *Stewartii* we do not know. By *Petargoniums* you mean, we suppose, the flowers known as Florists' Geraniums. You wish to know the names of a dozen or more suitable for a new beginner, and you add, "not too tender." You are, indeed, a new beginner, or you would know that all *Petargoniums* are tender, and that there is very little difference in their constitution. Proceed the following, they will please you:—*Optimum*, *Astrea*, *Lagonia Kulla*, *Conspectum*, *Chieftain*, *Enchantress* (Foster's), *Governor*, *Incomparable*, *Lord Mayor*, *Magnificent*, *Magnet*, *Mohanna*, *Purple Standard*, *Pearl*, and *Virgin Queen*. If you do not mind expense, add *Regalia* and *Virginia*.

VERBENAS FOR CUT TRUSSES (*M. C., Dublin*).—The following *Verbenas* truss well, and are good for exhibition:—*White*, Smith's *Alba Magna*; *Blue*, Caie's *Blue Bonnet*; *Crimson*, Barker's *Conspicua*; *Pink*, Turvell's *Ariel*; *Scurlet*, Smith's *Monsieur Julien*; and *Purple*, *Monsieur Paquin*.

MUSK DUCKS (*J. D. K.*).—You can obtain their eggs from any dealer, or specimens of the birds themselves. Those entirely white are said to be the best.

CLEANING ROSE LEAVES (*An Enquirer*).—Nothing more is required than tepid water and a sponge. It will remove all the soot and dust. The oftener it is applied the better the Roses will thrive.

DIRECTION (*A. A.*).—Mr. Turner is a very respectable man; his direction is "Parkwood Springs, Neepsend, Sheffield."

VEGETABLE MARROW (*Adolphus Yates*).—Sow the seed in small pots, and plunge in a gentle hotbed early in April, and turn out the plants into a warm, rich, sheltered border, giving at first a little shelter during May. They require no culture but to have the branches trained regularly over the ground.

ROUF ADVERTISEMENT (*Vectis*).—Not knowing anything about the advertiser we cannot give an opinion.

WHITE MULBERRIES (*A Subscriber*).—Write to Mr. G. Balchin, Spring Place, Godalming, Surrey.

ERROR—p. 427, col. 2, line 40 from the bottom. For "Pencilled Game Fowl," read "Tasselled Game Fowl."

AMERICAN POULTRY BOOK (*F. L.*).—We cannot give any information about it. It is quite worthless.

ADVERTISEMENT (*Harriett*).—It would be 3s 6d.

COCHIN PULLET (*A Young Beginner*).—Never mind the rattling in the throat, as the pullet is quite well.

SAND FOR CUTTINGS (*G. A. G.*).—Silver sand is the best for striking cuttings.

DWARF PEAS (*T. Burgess*).—We know of no good Peas only one or two feet high. The shortest which we know that are really good are the *Scimitar*, *Spanish Dwarf*, *Imperial Blue*, and *Dwarf Green Marrow*.

INFLUENCE OF THE MALE PARENT.—*H. T., of Birmingham*, asks—"If I take away from my Cochon hens a cock that has been with them since Christmas last, and substitute another, how soon shall I get genuine eggs by the last cock?" Another correspondent asks the same question as to *Game Fowls*. We can only reply, that as a hen of any breed will continue to lay fertile eggs for about three weeks after being entirely removed from a male bird, it cannot be safe to depend upon a fresh cross until after the lapse of that period. The subject, however, does not rest there, for there are evidences to show that characteristics of the first male will appear in the progeny occasionally for the remainder of the female's life. It is a mysterious subject strongly illustrative of the text—"These two shall become one flesh."

BLACK MALAYS (*M. T. G.*).—We do not know this variety, but will give you a fuller answer next week. We should have thought them to be "Pheasant Malays," only you say they are "perfectly black," and have "yellow legs."

KNOWLEDGE v. IGNORANCE (*S. Amey*).—We are obliged by your paper; but why combat a phantom? Mr. Stansbury means as you do, "a little learning is a dangerous thing."

ALOE (*A Constant Reader, Co. Dublin*).—We presume you mean the *Agave Americana*; and if so, the late winter was not only cold enough to kill it, but has done so according to your description of its appearance.

VALUE OF LAND IN AUSTRALIA (*F.*).—The following will give you an answer:—"VALUE OF LANDED PROPERTY IN BRISBANE.—An allotment containing 33½ perches, at the corner of Queen and George-streets, North Brisbane, has this week changed hands for £620. The allotment has nothing on it but a fence; but it is an excellent situation, and has three frontages; 3 acres, 1 rood, and 21 perches at Kangaroo Point, the cost of which, when purchased some few years ago, was £50, has recently been sold for £400. A small brick cottage, and the allotment on part of which it stands, in Queen-street, was purchased less than six months ago for £400, and has this week been sold again for £1000. These sales have been effected by private contract."—*Moreton Bay Courier*.

LAND SALE.—The most important sale of land ever held in Brisbane, whether we consider the quantity of land offered for sale, or the high figure at which most of the allotments were purchased, took place at the Court House, on Wednesday and Thursday last. There was present the largest assemblage of bidders we ever witnessed, and the biddings were very spirited, parties appearing determined to secure their favourite allotments at any price. The most extravagant rate given was for allotment 6 of section 28, purchased by Mr. Gibbon for £210, being at the rate of £1000 per acre. The extraordinary high rates given for allotments at the intended village of Sandgate struck every one with astonishment, and led the more thinking portion of the community to believe that a mania had seized the purchasers. However, the result of the sale, which realized £15,000, sufficiently evince the improved prospects of the town and district, and the increasing demand for land. Only three country lots remained unsold at the close of the sale, and these were afterwards taken at the upset price, whilst we have every reason to believe that very few of the deposits will be forfeited."—*Moreton Bay Free Press*.

LONDON: Printed by HARRY WOOLDRIDGE, Winchester High-street, in the Parish of Saint Mary Kalendar; and Published by WILLIAM SONERVILLE ORR, of Church Hill, Walthamstow, in the County of Essex, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—March 16th, 1854.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 52.2° and 33.8° respectively. The greatest heat, 75°, occurred on the 27th in 1830; and the lowest cold, 14°, on the 25th in 1850. During the period 118 days were fine, and on 71 rain fell.

BRITISH WILD FLOWERS.

(Continued from page 453.)

CARDAMINE HIRSUTA: Hairy Lady's Smock; Lesser Hairy Cuckoo Flower.

Description.—It is an annual. Root of many white fibres.

Herb variable in size and luxuriance, deep green, more or less hairy, rarely quite smooth. Stems from three to twelve inches, or more, in height, usually several, erect, usually furnished with lateral branches of various lengths, leafy, angular, often zigzag, hollow in the centre, clothed with fine, prominent, scattered hairs. Leaves alternate, all pinnate (leafleted). Stem on short stalks, without stipulas; leaflets stalked, sometimes alternate, all for the most part somewhat hairy; those of the root-leaves roundish, or heart-shaped, coarsely notched, numerous, and forming a circle on the ground; those of the lower or middle part of the stem more oblong; the upper ones narrow-reversed-egg-shaped, or quite line-like, blunt, generally entire, but in this respect, as well as in length, they vary. Flowers small, in a flat, upright cluster. Petals white. Two shorter stamens often wanting. Pods in long clusters, erect, slender, smooth, or occasionally hairy, their valves undulated by the projection of the seeds; stigma almost stalkless.

Time of flowering.—March to June.

Places where found.—It grows on dry, gravelly banks sometimes, but occurs most frequently in moist shady places. Not uncommon.

History.—Some botanists have considered this to be merely a variety of the *Cardamine parviflora* of Linnæus, a species not native of England, but the short pods, bushy stem, and differently-shaped leaflets show that *parviflora* is another species. The present species, *C. hirsuta*, has a stronger flavour than *C. impatiens*, and in Ray's time many persons used it as a salad herb. — (Smith. *Withering. Ray.*)

The word *Ehaloeth* is used in the Old Testament to describe both a wood and the tree from which it was obtained. In the first case it is translated in our version ALOES, and in the second case as LIGN ALOES.

Wherever the wood, or its produce, is mentioned, it is in connection with two aromatics—Myrrh and Cassia (*Psalms* xlv. 8; *Prov.* vii. 17), and with some others by Solomon, who says, in *Canticles* iv. 13. 14—"Thy plants are an orchard of Pomegranates, with pleasant fruits; Camphire and Spikenard, Spikenard and Saffron; Calamus and Cinnamon, with trees of Frankincense; Myrrh and Aloes, with all the chief spices."

The mixture of aromatics last mentioned appears to have been in high esteem, and to have been that especially preferred by the Jews for embalming purposes. Thus we are told that "Nicodemus, which at the first came to Jesus by night, brought a mixture of Myrrh and Aloes, about an hundred pounds weight. Then took they the body of Jesus, and wound it in linen clothes with the spices, as the manner of the Jews is to bury." (*John* xix. 39, 40.)

The quantity thus employed has been objected to as

excessive, but it is certain that the quantity of spices and fragrant gums either burnt, or applied to the body upon such occasions, was always proportioned to the honour intended to be paid to the deceased. Thus at the funeral of Herod there were five hundred spice bearers; and at that of Gamaliel eighty pounds of Opobalsamum alone were used, to say nothing of other aromatics. (*Joseph Antiq.* l. xvii. c. 10. *Talmud, Mess-achoth Semach.* 8.)

The *Ehaloeth* was used, however, for other purposes, and amongst these the perfuming of bedding and dresses are specified in the texts which we have quoted. For such purposes resins would not be suitable, and this seems a testimony that the wood itself imparted the perfume. This is corroborated by some of our best Hebraists who agree that the word employed in the Old Testament uniformly denotes a kind of wood or tree.

This suggests the question, by what name is that tree now known? Dioscorides, and some modern Arabians, with a few intermediate writers, have called this wood *Agallochon* or *Xylaloe*, which is a compound word, meaning "The Wood of Aloe." Why they should so

call it, though the interpreters of our Bible adopted the name, is difficult to explain. *Aloe*, however, we may observe, is the Hebrew name deprived of its initial and final letters.

We find that the Tradescants, those "treasurers of Nature's rarities," had "*Agallochum*" among the woods (*Ligna*) enumerated in their Catalogue of the *Museum Tradescantianum* (p. 31). Of this very specimen we have the following narrative by Parkinson, under the title of "*Agallochum* or *Lignum Aloes*." "I have seen with Master Tradescant, the elder, before he died, a great piece of true *Lignum Aloes*, and of the best sort, as big and as long as a man's leg, without any knot therein, which, as he said, our King Charles gave him with his own hands, but was here kept before, and accounted by many as a great religious relic, even to be a piece of the wood of that Cross whereon our Saviour was crucified, and therefore was fetched away again from his son (Tradescant junior) to be kept as a monument or relic still." (*Theatrum Botanicum*. 1565.)

This *Agallochum*, we are of opinion, was the wood of one or other of the two trees now called by botanists *Aquilaria agallocha* and *Aloexylon agallochum*. The first belongs to the Natural Order of *Terebinths*, or Turpentine, and the second to the *Legumes*, or Pod-bearers. They are both of the Linnæan class and order *Decandria Monogynia*. The following note by Mr. Don is applicable to each of these trees:—"The wood is white, and has long been used as a perfume. Aloes wood is held in high estimation in the East on account of its fragrant odour, and as a perfume is applied to clothes and apartments, as well as a cordial medicine in fainting fits, and in cases of paralytic affection. By the Chinese and other heathens it was used as incense at their sacrifices.* In the East Indies it was formerly deemed of greater value than gold, and various fables have been invented as to the origin of the tree that yields it. Some have feigned that it grew in Paradise, and that it was conveyed from thence by the rivers overflowing their banks and sweeping away the trees. (*Don's Dichlamydeous Plants*, ii. 464.)

A perfume so precious, and of such imagined origin, may well have found praise in the verses of the Hebrew Poet; may well have been selected by the prophet as a simile for the tents of Israel; and may well have been selected as appropriate for embalming the body of our Lord.

It is no valid objection that the trees we have named are natives of the East Indies, for we have abundant proof that for such costly products of the East the merchants of Tyre visited and trafficked with the inhabitants of India. We have had occasion to notice this traffic in our notes upon the *Amoy*, and shall have to notice it further when remarking upon the *Calamus*.

It is an erroneous induction that by *Aloes* some native tree of the Holy Land must have been intended, otherwise Balaam, in his prophetic simile, would not

have compared to such trees the tents of Israel. So far is this from being the case, that we find in these highly poetized utterances the most costly products are referred to without any restriction as to the place of their birth. Thus Solomon, when narrating the plants of his ideal gardens, brings together with Pomegranates and other products of the temperate zone, Calamus and Cinnamon, which live only beneath a tropical sun. (*Canticles* iv. 13, &c.)

Balaam, in the simile alluded to, said that the Israelitish tents were "as the trees of the Lign Aloes which the Lord had planted." That is, which grew vigorously and naturally. Thus in another place it is said, "The trees of the Lord are full of sap, the Cedars of Lebanon, which he hath planted" (*Psalms* civ. 16). Under the term sap is included all the liquid products of a plant; and it may be noticed that the value of the wood of the *Aquilaria* and of the *Aloexylon* are just in proportion to their size, or vigorous growth, and the resinous secretions which they contain.

Our country friends, who drink each out of his own well and his own cistern, have a great advantage over the inhabitants of large towns—an advantage increasing in proportion to their nearness to the natural sources of rivers, and consequent remoteness from river mouths. Good water is confessedly only one of a hundred indications (natural, moral, social, and, we may safely add, political and religious*) which we are bound to follow out and adopt, if we hope materially to improve our sanitary condition; and its influence is much more indirect than has been taken for granted; yet no readier test suggests itself to us of the advancement of a refined and intelligent civilisation than the care bestowed on an artificial water supply; a subject which we hope to resume in a future paper.

Dr. Kidd says, in his "Treatise on the Adaptation of External Nature to the Physical Condition of Man," "Although there is scarcely any substance which water is not capable of dissolving to a certain extent, and, consequently, no natural form of water is pure, yet, in almost every instance, the natural forms of water are not only innocuous but salutary." And Dr. Smith, in a paper read at Edinburgh, before the British Association, has proved that well water is ordinarily freed from accidental pollutions in the process of filtering through the earth. When, unfortunately, from long occupation, or neglect, or other causes, the whole subsoil where we inhabit has become so charged with animal and vegetable refuse and corruption that the very water of our wells is tainted, it is obvious that the purest water brought from a distance can be no more than a pallia-

* Ray, in his *Historia Plantarum*, ii. 1508, says, It is very costly, and on that account was strewed on the funeral pile of the Princes and Priests of India.

* The following is from that portion of the Report of the College of Physicians contributed by Dr. Gall. "The immunity of the Jews in this metropolis was better ascertained, and, according to good authority, depended upon their attention to hygiene (or rather to their sacred law.) Their houses are cleansed annually, and are not overcrowded. They are, as a class, sober, and in their diet, scrupulous. There is no extreme destitution among them, their wealthy classes relieving those in distress. Their Sabbath is rigidly observed as a day of rest.—Page 160, *Reports on Epidemic Cholera to the Royal College of Physicians*, by Dr. Bailey and Dr. Gall.

tive. The necessity for a large adventitious water supply, then, argues a sanitary condition not altogether natural—not to be compared with thy happy lot, gentle reader, whose waters are thine own, and not strangers' with thee. *Thy* fountains are blessed.

In a former paper (in October last) we ventured to assure the readers of this Journal, that if the water which *they* use be not offensive at all to their senses, it will rarely prove unwholesome; and that it is rather in the form of vapour diffused through the atmosphere, than in a fluid state in our drink, that *water is likely to prove the means of spreading cholera and other plagues*. This point is beginning to excite considerable attention; and, at the risk of appearing paradoxical, we must beg to enter into some details for the edification of our country friends.

The thick-and-thin advocates of a water in no case beyond four-and-a-half degrees of hardness by Clark's test, along with water-closets inside the house, and water-tight sewer pipes four inches in diameter, have invariably adduced a certain pleasant little country town in the Lake district as their chosen standard of health and longevity. Reckoning the cost of the above necessities of existence at about £10 or £15 per house for any given town, and then, as a set off, comparing the value of life in the town proposed to be improved with the value of life in the town of Ulverstone, taken as a standard, it has always been proved that these really valuable improvements cost nothing at all; the money laid out upon them forming a most desirable investment of capital. But about two years ago, the gentlemen of Ulverstone bethought themselves that they would have a water company; and the fact was then established that this very healthy town had a water not at all answering to Clark's test, with very primitive arrangements, indeed, in the way of water-closets and house drainage.

Conversely—in a small manufacturing town at the other end of the same county, contrasting unfavourably with Ulverstone in everything relating to health, an abundant supply of water of four-and-a-half degrees, Clark's test, has been introduced within the last few years. One half of the people now use this excellent water, but the mortality is in no way diminished. An improved water supply has been provided for a large country town much nearer London, with a similarly indecisive result on the health of the place.

Our friend, Dr. Popham, relates, that at Cork, some years ago, a very bad form of dysentery was attributed to the water of the place. A very pure spring was brought in from a distance, and the disease disappeared for a long time, but with the famine it reappeared, and continued defying the water supply.

A short time ago, a whole family died, near London, of malignant fever, after drinking some water out of a ditch bottom. This last, in strict agreement with certain established principles, was set down as the cause of death. On analysis it was found full of vegetable, &c., remains, and was pronounced unfit to drink unless filtered; but some arsenic which had been swallowed in

the food was suggested as a supplementary cause, at least, of the illness of the family.

The Tyne, under new and enlightened arrangements of liquid sewerage, receives the drainage of Newcastle, where the cholera was most prevalent within the atmospheric influences of the vapour from the river. The town has been lately supplied with Tyne water, to a certain extent, taken from a higher source; a questionable proceeding, no doubt; but a house to house visitation failed in proving either that the districts supplied from this dubious source suffered most from cholera, or that those drinking the purest water suffered the least. Something more, then, than bad water is required to cause death; and something more than pure water to prolong life.

This point has received the fullest examination by the Committee of the Royal College of Physicians, whose report on cholera is now before us. A report which we must beg to refer to, once and again, as a mine of facts and illustrations of the whole of the very difficult subject which we have in hand.

"This theory, then, as a whole, is untenable. It has, however, directed attention to circumstances which may be hereafter shown to bear a part in the production or increase of this as well as other epidemics; and the enquiries it suggests must not be neglected, when the causes and mode of propagation of such diseases are again made the subject of investigation. It is not probable that in the case of cholera the influence of water will ever be shown to consist in its serving as a vehicle for a poison generated in the bodies of those who had suffered from the disease. But it may be proved that the poisonous matters which produce cholera, as well as other epidemic diseases, are capable of increasing in foul water as well as in foul air. At all events, it is scarcely probable that water containing putrid matters in a state of solution or suspension can be habitually swallowed without, at least, the risk of injury to the health. This subject needs, and is likely, henceforth, to receive more systematic investigation. Already, indeed, since the last epidemic of cholera in London, one mode, in which a large surface of water contaminated with the foul outpourings of sewers may largely contribute to the unhealthiness of a city, has been set forth with scientific precision by Mr. Farr. With the aid of calculations made by Mr. Glaisher, he has shown that in the summer season *as much, probably, as four million gallons of water rises daily* in the form of vapour from the surface of the Thames, at London, carrying with it into the atmosphere some portion of the putrid contents of the river."—(*Dr. Baley's Report*, p. 213, 214.) J. J.

"THE Bath and West of England Society for the Encouragement of Agriculture, Arts, Manufactures, and Commerce," under whose auspices so successful a Poultry Show was held at Plymouth, in June, 1853, propose to hold their exhibition for the present year at Bath, on the seventh and two following days of the

same month next ensuing. Chickens, we observe, are specially required, in addition to adult birds in the Spanish, Dorking, and Shanghai, varieties, the remaining classes being open to birds of all ages. The prize-list stands much in the usual form, but we must confess ourselves surprised to find that the premiums for Geese, Ducks, and Turkeys, of such limited amount in comparison with those offered for fowls; for, while many of the latter have £3, £1 10s, and 15s for the first, second, and third, respectively, none of these "farmer's" birds obtained more than £1 for a first, and 10s for a second prize. At a meeting of so strictly an agricultural character, the contrary policy, we should have imagined, would have been preferable.

The rules are clear and precise, and under the same able management of the director, Mr. Gray, by whom the arrangements of the Plymouth Show were so admirably conducted, we venture to anticipate equal success for the Bath meeting.

THE meeting of the *Entomological Society* for March was held on the 6th inst., and was fully attended, with the President, E. Newman, Esq., F.L.S., in the chair.

The Secretary announced, with a view of obviating some of the inconveniences which had been experienced in former years, that the Council had resolved thus early to announce the days for the two *annual excursions*, namely, on the 10th of June to Pembrey, near Tunbridge, Kent, and on the 5th of July to Mickleham, both excellent grounds for collecting, and of easy access by railroad. Tickets, taken before the 2nd of May, are to be charged half-a-crown; after which time the price will be raised.

Mr. Westwood called attention to a periodical work, the publication of which had been recently commenced, and which, from an examination which he had made of it, appeared to be a clumsy compilation from "Stephens's Manual;" the figures were also worthless.

Mr. Curtis exhibited a series of larvæ of various insects recently captured by himself on the continent, including those of a supposed species of *Ophonus*, one of the ground-beetles, and of *Stenoloppus vaporariorum*, another of the same tribe; those of *Cistela atra* and *Prostomis mandibularis*, the latter a curious beetle, the larvæ bearing a strong resemblance to that of *Pyrochroa*, and found under the bark of decaying Chesnut-trees; the larvæ of a supposed *Helopterus*, a clavicorn water-beetle, and that of a *Pyralis*, which is very destructive in boxes of preserved insects, spinning its web over the specimens, which it gnaws to pieces. Mr. Curtis also called attention to the curious fact, that many of the rare varieties of butterflies exhibited at previous meetings of the Society had been taken in the neighbourhood of Ipswich and Colechester; he likewise mentioned several other similar instances in which the same locality had produced other varieties; and Mr. Samuel Stevens exhibited a fine variety of the White Admiral butterfly, *Limenitis sibilea*, also from the neighbourhood of Colechester. The latter gentleman also exhibited speci-

mens of a species of *Burnet Moth*, recently captured for the first time in Galway by Mr. Milner. It is the *Anthrocerus minus*, and is distinguished by the large patch of crimson on the fore wings, not broken up into smaller spots. Likewise a number of beautiful Lepidoptera, from the north of China, recently sent home by Mr. Fortune, who is again engaged in Natural History and botanical pursuits in the *flowery empire*. (We take this opportunity to mention, that since the Meeting, we have received, from St. Petersburg, a memoir on the *Lepidoptera* of the neighbourhood of Pekin, sent home from the Russian Mission, which has been established for several years past in that city.)

Mr. J. Stevens also exhibited a number of beautiful butterflies and moths, collected at Port Natal by Dr. Guenzius; and also a specimen of the magnificent *Morpho Cypris*, belonging to the Society (forwarded from Bogota by Mr. Stephens), which, having become saturated with grease, had been entrusted to him to be cleaned. He had accordingly immersed it for three days in camphine, and had then covered it with pounded magnesia, and it had by this means become perfectly restored to its former splendour, being, in fact, the most beautiful of all hitherto known butterflies.

Mr. Frederick Morre exhibited a quantity of cells of clay, manufactured by some Indian species of Mason Bee or wasp, collected at Dacca; the greater number contained a pupa case, and in one of the cases a beautiful parasitic *Chrysis* had been found; whilst, in another, which did not contain a case, was found the pupa of a species of *Vespide*, the parent of which had probably taken possession of the cell already built by the real architect.

Mr. Desvignes exhibited a beautiful variety of *Melitta Dictynna*; and Mr. Foxcroft a quantity of whalebone shavings, infested to a considerable extent by the larvæ of one of the *Tineidae*, which reside in portable cases, probably *Tinea pellionella*; as well as the larvæ and perfect insects of *Boletophagus crenatus*, a small beetle found in the Boleti, growing upon beech trees in Perthshire, where it had been first discovered by Mr. Foxcroft, two years ago.

Mr. Dale forwarded a notice of the capture of *Hemerobius dipterus*, a new British species, at Langport, in Dorsetshire. This species had been previously described by Dr. Burmeister, in his Handbuch, ii., p. 973.

The President read a notice from Mr. Rawnsley, of Moreton Bay, New Holland, in which he expressed his willingness to collect objects of Natural History and Botany upon reasonable terms. This is an excellent opportunity, of which we trust our botanical as well as entomological friends will avail themselves. A similar statement was made from Dr. Reichardt, the curator of the Geological department of the Royal Museum at Copenhagen, who is about to proceed to Minas Geraes, and other parts of Central America, and who offers to collect insects, &c., on remarkably low terms. Parties subscribing for three years, at £12 per annum, are to receive a large amount of objects in return.

A paper was also read from Dr. Reichardt (a transla-

tion of which, by Dr. Wallieb, was commenced by Mr. Spence), on a *luminous larva*, found at Lagoa Santa, in South America, where it has been found creeping from beneath the timber flooring of houses. Each segment of the body emits two patches of greenish light on the upper surface, whilst the head shines with a ruddy light, like a burning coal. It was supposed to be nearly allied to the Glowworms, and to the Luminous Paraguay Worm of D'Azura. A notice was also read of the introduction to Malta, from Assam, of the Indian Eria Silk Moth (*Bombyx Cyathia*). This insect is of very large size, and feeds upon the Castor Oil plant. Its silk is very strong. The notice had been published, with details, in the Journal of the Society of Arts of the 3rd of March. A long paper by Mr. Newport was read, affirming the priority of the discovery by himself of the larvæ of *Monodontomerus nitidus*, a parasite on *Anthophora retusa*, one of the Mason Bees.

COLLECTIONS of dried *British Ferns* and their allied plants may now be had complete of Mr. F. Y. Brocas, who pursues the occupation of a British Naturalist, at his residence, 10, Tavistock Street, Covent Garden. He will readily assist in the purchase or exchange of any specimens connected with the zoology or botany of the British Islands.

It is a general remark that *Oranges* were never before so stained in the rind as they are this year. The brown, rough stain complained of seems to be the result of the attack of some minute Fungus like that which attacked the Grape.

Some months ago the formation of a *Pomological Society* was advocated in these pages, and steps are now taking to carry out the suggestion. We shall shortly give more particulars.

TRAINING PEARS.

I MUST now offer a few further remarks on Pears, and in so doing will take a glance at the various modes of training. At Oulton, we have chiefly table trellisses, umbrella training, horizontal-radiate, and a kind of hollow form, and on the walls, curved-parallel training, and a few on the old fan form. There are many other modes practised, according to the varying fancies of persons, for, after all, there is less importance in the mode of training than some people imagine. Any mode of training which will best allow the sun's rays to act on the foliage in general, tend best to equalise the sap, and provide for the most warmth, is, in my opinion, the best; and in this respect two or three forms may claim almost equal merit.

For my part, I have found the *table trellisses* the best, although it must be admitted that some kinds do not succeed so well on them as on others; indeed, the same may be said of any form. The table trellisses are four feet six inches wide, and are about a foot to fifteen inches above the ground level. The main branches, on which are tied down the young spray, are about one foot apart in parallel lines, running north and south. The trees were planted about eighteen years since, and my intention was to have a metallic table of strong, well-stretched rods, over which I would have placed a

metallic rail along the two sides longitudinally, running east and west; this rail about a foot above the table; and on this I would have worked a roller covered with canvass, something after the manner of carriages on a railway; the canvass rolled along every afternoon through September, and until the fruit was gathered, and again through the spring, to retard frost, and then to protect. This plan was, however, thought too expensive, and fell through, and I was obliged to have recourse to hobs driven in—rough stakes in the form of the letter **V** &c.,—and thus things proceeded, the sticks, of course, requiring almost annual renewal.

This mode, or something close to it, I fairly broached in "Loudon's Magazine," and strongly advised some of our market gardeners to lay down an acre or more at once, on a similar principle; had they done so in those days, they would, I am persuaded, have found it a profitable investment, and we should scarcely have heard of Orchard-houses. I wish I could even now cause my voice to be heard on this subject, for assuredly our Pear culture, in the main, is quite unworthy the age we live in.

I had, about twenty-two years ago, planted a border 240 feet in length, somewhat in accordance with those principles connected with root-and-branch culture, which had long been lurking in my mind, and which I have continually (my opponents may say, pertinaciously) adhered to up to the present moment.

These were a sort of "wood note wild," a sort of off-hand guess, but quite excusable in the position of affairs at that period, at which the complaints about barren wall-fruit-trees, espaliers, and, indeed, all but those of our good old orchards (which had escaped a coddling system), were to be heard on all sides. This line of Pears, however, though a first attempt, has turned out very well, on the whole; quite sufficient, I am told, to justify the adoption of a dwarfing system—albeit, a coarse beginning.

I must here observe, that I have coined a term or two expressive of the modes of training adopted; a course which no man is more unwilling to pursue than myself, but, nevertheless, a necessity, inasmuch as we have no existing mode of expressing the practice.

The *umbrella mode* will be readily conceived by those who have not seen it in practice; in form, and even size, the trees may be aptly enough compared to the skeleton of a huge gig umbrella, but even a little larger still. The stems (or umbrella-handles, shall we call them?) being about four feet high, and the leading branches touching the ground within nine inches. These, for lack of proper frame-work of rods, are supported by the **V** stakes before described. It may here, however, be observed, that these trees, having been about a score years under training, are so sturdy, that the boughs, in the main, carry their own weight readily. I have umbrella-trees here, no bigger than a gig umbrella, which measure inches around the trunk; they are singular-looking things, and look as if it would require no small amount of power to topple them over.

The mode for which I have coined the term *horizontal-radiate*, was the first experiment in the horizontal way with me. A border, five feet wide, being set out, the trees were planted down the centre at about fourteen feet apart, and the main branches were then trained in a radiate way from the centre, and horizontally at about a foot above the ground-level; it will be here seen that there is an identity of principle between this plan and the table trellis before described; indeed, this may be better termed *radiating table-training*, the other, *parallel table-training*, and so forth. Our ingenious readers will, doubtless, pardon me for being a little "fussy" over the affair, for I must needs be explicit; this being the last time, in all probability, in which it will be requisite to be so special in detail, although I dare

scarcely say, as our histrionic gentlemen sometimes do—"The last time of performance in this character, &c." If any one is to blame, it is my very clever and worthy coadjutor, Mr. Fish, who fairly challenged me to an explanation of the whereabouts in Pear culture.

The *balloon form*, as some have termed it, is not well characterised by that term; it is neither more nor less than two or three stories high of umbrellas, one above the other, and each, of course, having, as all good umbrellas should have, a proper length of handle. I do not commend these gim-craeks or horticultural vagaries, neither do I condemn them, for I have had a tolerable share of success with such whimsies; they are the mere offsprings of a sort of inventive mania entertained many years since. However, it becomes a duty, now that I have fairly broken the ice, to point to the merits and demerits of all that I am acquainted with. I may observe, that I have a *Marie Louise* tree in this character, and it has been a marvel to all who have seen it; three stories high, and laden with those fine Jargonelle-looking fellows, like the ornaments dangling around a Chinese Pagoda. This *Marie Louise* has three of these umbrellas, each gradually diminishing in size upwards, so that it might almost be termed a ereeping pyramid; it has, altogether, a very handsome appearance.

The *curved-parallel* mode on the walls has only one advantage over ordinary fan training, as far as I am aware, and that is, light is admitted *more equally* to all portions of the tree. In this respect, ordinary fan training has ever a slight defect. The main shoots, in this curved-parallel mode, start from a common centre, as in fan training, that centre about a foot or little more above the mere collar. They are forced into a curvature at about half a yard from the point of radiation, and then fall in with the courses of brick-work, observing horizontal lines at the distance of three courses apart.

A mode of training adopted at the Royal Gardens, Frogmore, is worthy of notice here. Many of the Pears, when I was last there, were trained over metallic *arches* of about four or five feet high, and, perhaps, five feet diameter at the base; as, however, I speak from memory, I may be slightly in error as to measurements, but that will not interfere with the principle. These are, I think, of an elliptic rather than a circular form, and are composed of parallel wires stretched, I believe, horizontally. Now, these I should have no objection to if running north and south; but as to their running east and west, I should, most decidedly, object to them, for they must, in that case, have a north or shady side, and it really will not do to advocate shade to forcing Pears; if so, there should be an end of all talk about tenderness. If I were establishing a new garden, I think I should use this form along the north and south lines, and the table trellis along the east and west lines; this would be a very interesting and useful arrangement.

Arcades of Pears along garden walks have been recommended, and, no doubt, look very agreeable when full of fruit, but they can scarcely be recommended, on the score of principle, for our tender kinds. But there are many kinds for which this mode would be suitable enough, and those intending to adopt it should be very careful how they make their selection.

As for *pyramidal* trees, everybody knows that they are very handsome, and, in the main, succeed very well; but in my opinion the table trellis will be found much superior as to warmth; the branches being all within a foot of the soil must be admitted to be in a warmer position than those higher up, especially if the ground beneath were covered with slates, and the shoots so trained as to permit the solar rays to heat the slates.

Besides, I think it will be found, that by some such plan as I have suggested, the table trellis may be covered and uncovered with greater facility than most

other forms; and this of itself is no mean recommendation.

In due time, I will proceed to examine other portions of this interesting, though somewhat perplexing, subject.

R. ERRINGTON.

MEETING OF THE HORTICULTURAL SOCIETY.—MARCH 7, 1854.

THE newest plant, and one of the prettiest greenhouse plants that has been introduced for a long time, was exhibited here to-day by two nurserymen, in two forms, diametrically opposed to each other; the one, the most miserable, scrubby, three-parts-starved-looking thing you ever saw; and the other, the most healthy-looking plant that has been publicly shown in England these ten years past. When one has an entirely new plant, it is right and lawful to exhibit it, even if it were half-dead at the time, for practical men know, full well, that it is not always the healthiest and best-looking plant among a lot of new seedlings that is the likeliest of them to flower, so we make allowance for the looks at the first start; but no such allowance was needed on this occasion, as the two growers are, by common consent, allowed to be the most successful growers, of their line, in all England, namely, the Messrs. Veitch, of Exeter and Chelsea, and Messrs. Henderson, of the Pine-Apple Nursery, where Mr. Appleby used to tend the Orchids. I once had the ugliest and worst-grown plant but one in England, but it was never shown before, and I beat Mrs. Lawrence with it out-and-out on the very same table, and got a Knightian Medal for it. The plant was *Tweedia coerulescens*, and the new plant to-day is called *Acacia Drummondii*, a New Holland plant, and the very best of the race, far superior to *grandis*, or any of the "new Acacias" we have heard of for years. Now, as this plant must soon get into all parts of England, Ireland, and Scotland, to the Continent, and to North America, as the best pot dwarf *Acacia*, on the authority of THE COTTAGE GARDENER, I must describe it, as I am convinced, in my own mind, that it is *constitutionally* a better seedling to grow than its fellow shown as above. Indeed, I tried to convince the best botanist in England that the two are two distinct species, but he would not have them so. The leaves, shoots, and style of growth of this *Acacia*, are just as if it were a cross seedling between *Coronilla glauca* and *Cytisus ramosus*, and that the *Cytisus* changed the hue and reduced the leaves of the *Coronilla*. The flowers are on cylinders, or cylindrical, and the footstalk of each cylinder is an inch or more in length, making it the more graceful. It was sent by Mr. Veitch, who had a good prize for it, and who also sent a new, or newish, *Boronia*, called *Drummondii*, a delicate-looking plant, with large, bright pink flowers; also *Sarracenia purpurea*, in good order. Mr. Hume, not the M.P., but the gardener to R. Hanbury, Esq., of the Poles, near Ware, sent a very beautiful, and very scarce, I believe, *Cymbidium*, called *eburneum*, with large, white, waxy flowers, and two on a scape. It seemed an excellent plant to grow, so that an amateur might try it without fear. The Messrs. Rollinson, of Tooting, sent a new *Lycaste*, a droll-looking flower, the sepals rolling back, showing a greenish tinge, blotched, and shaded with brown, and the petals whitish, and blotched and shaded like the others, but with purple instead of brown. This *Lycaste* was just beginning to grow, so that it may, probably, be had in flower from February to May, or, perhaps, in the autumn, for it is worth while bearing in mind that a great number of bulbs,—*Hippocrepis*, for instance,—and a great many Orchids, *flower shortly after a long rest*, and, therefore, that many such can be had in flower any month of the twelve, by first arrang-

ing the times of growth and of rest. The Messrs. Henderson sent a good plant of *Brachysma acuminata*, with the flowers all ready to open, when they are of a rich crimson-scarlet. This is really a good greenhouse plant, that seems easy to grow and look well; they also sent *Bilbergia iridiflora*, one of those young Pine-apple-looking plants which are so conspicuous from the bright scarlet bracts which accompany the flowers; and a very healthy young plant of *Franciscea confertiflora*, in good bloom, together with the *Acacia Drummondii*, which, I believe, is quite a different thing from the one exhibited by Mr. Veitch. Also, a very large plant that would come in well to fill up a corner of a room when company, or a ball, or wedding, was expected: this is called *Conoclinium ianthemum*; it was three feet high, and four feet in diameter; the flowers are in large heads on the tops of the branches, looking as if they were a cross between the blue *Ageratum* and a purplish Colts-foot (*Tussilago*), or bluish, with a tinge of purple; most of the branches were cut-in last year to eighteen inches, their bottoms are now quite hard wood, and the new top parts are soft-wooded, and looking as if all the plant ought to be as soft as they. By a system of growing this plant as they do young Hydrangeas, for one large head to a pot, it can be had in bloom in a three-inch pot, and, I believe, a little plant, with a big head in this way, which I saw on the table, was from the garden of the Society. At any rate, there it was to prove the fact, which is well worth keeping in mind, as any flower you can stick in a little vase on the corner of the mantelpiece, when friends come in for the evening in winter, is as good as a prize plant in May or June. For the same reason, people ought now to push on duplicate plants of as many of the dwarf *Acacias* as they can get room for; get them through with their flowering as quickly as possible; then prune them in as close as a Cabbage Rose; force them to make a quick growth, by keeping them close and a little warmer than a greenhouse till the middle or end of May; put them out-of-doors after the turn of Midsummer, and in the full sun, if they can stand it, or as soon as they can; not to leave them out too long in September, and they will be in bloom for the rooms, or conservatory, early in the new year; and by going through the same process in 1855, but two months sooner, they would be ready for a gentle forcing early in November, to come in with the first Camellias and Chinese Azaleas, and in the very middle of the Chrysanthemums in their season. I never saw this class better done in this style than by my successor at Shrubland Park, last autumn, the pots standing on a bed of white sand, but not plunged, which was in favour of their ripening so well, and of their being so abundantly in bloom-bud. The *Azalea squamata* I mentioned the other day, would freely yield to this treatment and make a change of tint among the usual flowers which come in before Christmas.

It is a great misfortune that most of the old *Acacias* from the Cape get so soon to be such trees and bushes that few can find room for them, as they could be brought in just the same as the new race from New Holland, and they are more varied in their leaves and style of growth; that is what I was thinking of, on seeing two very nice plants of the old *Acacia longifolia* from the collection of the Society. I think they were only in No. 24 pots, but they were six or seven feet high, wide in proportion, and clothed down to the pot; they were also in such profusion of bloom, that if I could but add new to them, I would run them up higher than even *Drummondii*. All we can do with these Cape *Acacias* is to keep a succession of young plants of them, and cramp them at the roots in small pots, and keep stopping them from May to September. When they get too big for us, let them be planted out-of-doors in May, and take their chance. They often escape in mild

winters; but, what is better than all, everybody can grow them. Among the high nobility, *Acacias* have become very fashionable within the last ten years; but as they come in when few people are about visiting large places, the great bulk of our plant people think they are too common for them to grow; so there is a fashion in flowers as in bonnets and dresses.

A fine, large plant of the now *Cytisus ramosus* was shown by the Society under the first name by which it was known, *Genista rhodopneca*, and their old *Trymalium odoratissimum* is now, probably, the best plant of it in Europe. It may be about five feet high, trained to a circular trellis, and not hard pruned, which is the great secret of its health and profuse flowering. Then, how is a plant, which grows and flowers exactly like *Ceanothus azureus*, made to bloom without being cut-in very close every year after flowering? Just as they manage that same *Ceanothus* at Shrubland Park; when it reached the top of the wall they merely thin out the old branches, and train down the young wood over the old parts, cutting off the points, here and there, when they are not thoroughly ripened.

The crimson-flowered *Azalea obtusa* was in this collection; also *Epacris lineata*, a light pink; *Epacris ardentissima*, a fine crimson; a very fine hybrid *Begonia*, a seedling from *hydrocotylifolia*, stronger in all the parts than that species; I forget the other parent, but it is not *maucata*, as was first given out. Some one had made a mistake in that cross; a large plant of *Dielytra spectabilis*, with better coloured flowers than is usually seen in forced plants of it; this is now, beyond a doubt, perfectly hardy, but no flower suffers so much from the least over-heating. *Azalea ramentacea*, another of Mr. Fortune's new China ones, a very dwarf, white-flowering kind, with thicker leaves than any of the old breed, and in that respect would improve the leaves of any of our white seedlings, and would also give them a more compact mode of growth. A magnificent cut plant of *Acacia lineata*, which has a close way of growth, with *Pultenea retusa*, full of pea-flowers, which are mostly yellow, and the best varieties of the Chinese Primrose, in sections of double flowers, with plain and fringed sorts. Also a large plant of the beautiful evergreen, hardy *Berberis Darwinii*, from a cold frame. It was a yard high, in a No. 16 pot, and very gay it was; and last of all, *Echeveria obtusa*, which deserves to be a window plant, and is all but hardy.

Of Fruits, we had only three fine bunches of the *Muscot of Alexandria* Grapes, turning into raisins, as they mostly do at this late season, but otherwise in good condition for table; with some pots of Onthill's *Black Prince Strawberry*, in 48-sized pots, but not done well; and Mr. Solomons spoiled a dish of Strawberries, which he sent from Covent Garden, by mixing *Keen's Seedlings* with the *Black Prince* in the same dish.

Thomas Good and Co., of South Audley-street, sent several rich-looking flower vases for rooms, stair-cases, &c., with stands, of different colours, forms, and workmanship, some of which were highly rich in colours—all had a good allowance for drainage. This class of vases is used by the great for holding plants in pots, which are changed as often as they get out of flower, or single specimens in pots. When there are more than one pot, some kind of stand is necessary to get up the rims of the pots to nearly the rims of each vase, and then to cover all the pots with green moss. One great error I have seen in this arrangement was to put a larger pot inside the vase than could be hid, giving one the idea that the pot was too big for the size of the vase, and if you pushed it farther down you must split the vase to pieces.

Of the most profitable timber, and of fancy timber, there were lots this time; and the subject seems to take uncommonly well among the lords of the soil, but ladies

are more cautious, and will not take to a thing, however new, until it becomes fashionable. The large plank of *Deodar* was lionized. Specimen plants of the *Cedar of Lebanon*, which were planted at Highclere in 1773, were sent by the Secretary of the Society, J. R. Gowen, Esq. A fine sample of the Douglas fir (*Abies Douglasii*), from Oregon. This wood is the best of all the Spruce Fir tribe, and is hardly second to that of the *Deodar* itself. A block of *Pinus insignis* showed that it is of no use, or likely to be here, except as a nurse plant, to keep up better trees of a slower growth. When it comes to be as plentiful and cheap as the common Spruce it will make a far better nurse, and it has begun already to bear cones in this country. This wood was sent by T. May Harding, Esq., of Upecott, near Barnstable. This Society would be pleased to receive more kinds of woods, specimens of British growth, as the Fellows have taken such interest in the question of profitable planting; and after a season such specimens could be returned. The fact is, this agitation about the mismanagement of the national forests has opened the eyes of a new generation of planters, and the end will be, that every new tree, and every untried timber of home growth, will be scanned and criticised till the pounds, shillings, and pence value of each is as well understood as the planting of the seedlings. We had, also, good specimens of the *American Larch*, or Hackmatack-tree, which does no good here. Also of the Corsican Pine (*Pinus Laricio*); but a specimen before us of the great Alerce wood of the old Spaniards, if not of the Moors, is, probably, the very best wood among all the Conifers. No one could make out what tree produced the Alerce for ages, or where it grew. The Moors introduced it, and, probably, had forests of it in Spain, although the latter is doubtful, from no mention being of it in a book written by a Moor in the twelfth century. This old Moor was no fool of a gardener, for he treats of all the trees and shrubs in Spain, and also how to transplant large trees as well as Harry Moor at this present day, but he makes no mention of Alerce-trees. Surely, such a good forester, however, would know the tree and wood most prized by his countrymen, and of which they roofed their temples, which we know to have resisted all weathers, during nine centuries, without a bit of paint. It was only nearly twenty years ago that we found out, through this Society, what the Alerce really is. Mr. Drummond, our Consul at Tangier, traced out the origin of Alerce wood to be a tree which is very common in Barbary and the Atlas range. It is of the *Arbor Vitæ* kind, and is now called *Callitris quadrivalvis*, alias *Thuja articulata*, or the *Sandarack* of Mount Atlas. He sent some of them to the Society, and we had it for examination and comparison to-day. Unfortunately, it will not do for foresting in this country, being too tender for the climate; yet, if we may put faith in the Spaniards, who went over and conquered Peru and the countries to the south of it, we have just as good Alerce wood as that of Barbary in the Alerce of Chili, either *Libocedrus tetragona* and *Libocedrus Chilensis*, or both, and both are as hardy as the Common Larch, and grow to a much larger timber. Then it follows, like A. B. C., that the Chilian Alerce is a powerful rival to the Indian *Deodar* and to the Oregon Fir of Douglas, if not superior to both, and that both are superior to the Larch, particularly the Douglas Fir, which will not warp or shrink under the most severe trials. At all events, that is about the marrow of the lecture, as far as my memory carries me, for the room was so full that I could not use my pencil where I sat.

D. BEATON.

KEEPING, PROPAGATING, AND BEDDING DAHLIAS.

A NUMBER of complaints have reached me this spring, that the Dahlias, though secured from frost, have kept very badly. It is too late to resort to preventive measures now for this season, and yet it may be a gratification for those who have been disappointed to know some of the causes of failure, that they may be guarded against in future years. One complains, that after securing them as carefully as Potatoes in a place not over dry, that many of the roots are completely decomposed; another finds that the roots have no substance, but are regularly mummy-dried; and a third finds, that though the bulk of the tubers are seemingly sound enough, the collar of the plant is so far gone that no coaxings of heat or moisture can induce a bud to break; while a fourth says, that though all his plants seem sound, no young shoots seem inclined to come. The first and second of these evils are generally attributable to unsuitable treatment of the tubers before storing; the third is generally the result of frost getting at the collar of the plant before it is taken out of the ground; and the fourth, when it does occur, is often due to a certain mode of propagating, which may be guarded against now, and which, though detrimental to some sorts, exerts no prejudicial influence on others, but which it is well to guard against in all.

The three first causes of failure may be guarded against by a very simple process, namely, going round the Dahlias as soon as frost is anticipated, and piling old tan, litter, or even the earth of the bed, which I generally use, round the stems of the plants, in little mounds, from six to twelve inches in height. This secures the collar of the plant from being injured by frost. After this, I prefer that the plants should stand in the ground until the tops are quite blackened by frost. The stems are then cut off about fifteen inches from the ground, and if more frost is at all apprehended, the top of the plant is laid over the roots, the part of the stem left being bent so as to prevent water entering and lodging there. If the plants are extra luxuriant, and the frost long in coming, previously to placing the mounds over the tubers a spade is inserted round the plant so as to cut many of the fibres, and thus check the rampant luxuriance. I prefer letting the tops stand until destroyed by frost to cutting them when at all green, because the cold nights, and the slight frosts that generally precede a cutting-down one, will have gradually checked luxuriance, and thrown more of a ripening influence into the tubers. In either of these cases, protected as I have mentioned, I would wish the roots to receive a further ripening by their remaining in the ground eight days or a fortnight after being cut down. If the frost, however, came too severe for the roots to remain in the ground with safety, and any covering with litter was deemed inadvisable, I would give the roots a similar advantage by lifting them with as many fibres as possible, and with what earth would adhere to them, and allow them thus to remain in a shed, the floor of a house, &c., where they would not dry too quickly, and thus the roots would be more gradually and thoroughly matured, and nothing of the sudden change experienced as would be realised by cutting down the green stems and storing the roots away at once. Whenever the roots are brought in-doors they should first be turned topsy-turvy, that every particle of moisture in the old stems left may be turned out. When thus left for a week or a fortnight, the old stems may be cut close, a part of the earth removed from the roots, and the tubers placed in any position, neither wet nor dry, and where frost will be thoroughly excluded. Small copper wire is about the

best material for securing tallies to the roots when the latter are placed in dry earth, sand, &c.

A few examples frequently give a better lesson than the most valuable directions. I knew an amateur, who told me, every summer, for some years, that he must send his best Dahlias for me to winter for him; but, somehow or other, they never came; and I know that for a number of years he had to get every plant from his nurseryman. I recollect, when pitting Dahlias, as used to be done with Potatoes, was all the rage, and no bad plan it is, that one gardener did not lose a single root, while another had scarcely a live tuber in his collection, though both had been equally secured against frost. In the latter case, the plants had been cut down when the tops were merely a little frosted, the tubers taken up, beautiful and fresh they looked, well cleaned from earth, properly named, and packed into their winter quarters at once, receiving a covering of straw and earth sufficient to secure them from frost. Of course, the roots were full of watery juices; there was little chance for these escaping, and fermentation and rotteness ensued. The first-named were treated as advised above, and afterwards stood for the best part of a month in a shed, exposed during fine days, and with a little protection in cold nights, before being pitted, and nothing could have answered better.

An amateur friend, who will not be at all offended when he sees this, some years ago obtained, at great expense, a collection of the choicest and newest Dahlias, and, no doubt for the double purpose of serving himself and testifying his respect for me, he proposed that I should get the tubers in winter or spring, start them into growth, get one or two plants of a sort for him, and plant the others remaining as I deemed proper. I saw nothing of the tubers until, I think, towards the end of February, and what a sight! They were worse than mummies, nothing but the skin being left. I had them wrapped in moss slightly damp, gave increase of temperature by degrees, did everything I could to swell the dried up tuber by degrees, but, after all, only two or three sickly plants could be obtained out of what the previous year cost the best part of a ten pound note. I knew whenever I saw them how they had been managed. My friend told me that he went out and found the foliage one night as stiff as a poker with frost. He was anxious to save his favourites, forthwith summoned his trusty man Friday, cut down the stems level with the surface, hoisted, with the help of a fork and the light of a lantern, as far as I remember, all the tubers out of the ground, and transferred them at once to the floor of his greenhouse, that floor being paved, and to a position on it near the flue, where they had remained until packed and brought to me. Here the treatment was different, to a very extreme, as contrasted with the case of pitting at once; but the two extremes met in producing a common disappointment, though varied in its appearance; the watery juices, in the one case, producing putrefaction and rotteness; and the too free exhalation of them, in the other, leaving nothing but a mummy skin behind. If the plants of our friend had remained longer in the ground, or if, when taken up thus suddenly, the roots, carefully moved, had been packed in *dryish* earth (not dusty dry) on the floor of the house, and at a distance from the flue, the disaster would not have been so likely to happen.

One case more. Two years ago, reports reached me, from various quarters, of the splendid effect produced by the dwarf Dahlia *Zelinda*, when grown in rows and beds; and I was promised, in several cases, a good supply, if I would only go for them. I had known the Dahlia years before and thought but little of it, having only seen it with others, and in solitary specimens in borders. I saw the first rows of it a twelve-month past, last autumn. The able gardener in

that princely establishment whence my supply was promised, on the principle, that "a bird in the hand is worth two in the bush," offered me and my companion some plants each, as he would soon be taking them up, the frost having just touched a few of the upper leaves that morning, and, without more ado, turned out a-half-a-dozen of roots for us. I carried them carefully home, potted them the next day, kept them neither moist nor dry, and in a temperature of from 40° to 45° during the winter, placed them in a higher temperature in the middle of February, and kept wondering and wondering how no vegetation was appearing, and on turning them out of the pot, I found the skin dying, and the interior of the tuber either wholly dried up, or like a mass of light rotten wood. I was rather chagrined, after all my labour, to have only this return; but I did not feel justified in attributing it altogether to the *immaturity* of the tubers, until, on writing to the friend that accompanied me, I learned that his roots had served him in the same way.

From these facts, it may be inferred that a sudden check to the roots, by cutting away the top when yet green and flourishing, is injurious to the keeping properties of the root; and that even when cut down with frost, it is advisable to allow the root to remain somewhat longer in the soil, in order that it may be more matured; and that this happens in the circumstances, is so far evident that roots so prepared seldom go wrong afterwards, if secured from frost, and if packed, or unpacked, in any other material, such as earth, sand, or moss, &c., are not exposed to the extremes of great dryness or much moisture.

After what has been said lately on *propagating*, I need not here enter upon the propagation of desirable kinds of Dahlias. The tubers are generally placed in a sweet hotbed, not over warm; and when the young shoots are from three to four inches long they are slipped off with a heel from the tuber, or the shoot is cut at a joint when it is desirable to get as many plants as possible, as the joints left below the cutting removed may be expected to yield each one or two cuttings. These cuttings are placed in light sandy soil, and inserted in the hotbed, when, if all goes well, they will soon strike root. Now, the peculiar mode of propagating to which I referred, is the not only cutting across at a joint, and removing the leaves there, but slipping down the knife on each side when doing so, and thus reviving not only the leaves but the buds in their axils; and in some sorts it has been found, that when this is done you may have a large, fine tuber in autumn, but no buds and shoots from it in spring. It is preferable, therefore, to have one or both of these buds at the base of the cutting when it is thus cut through at a joint. So thoroughly are first-rate *Dahlia* growers convinced of the truth of this, that when they purchase a desirable and expensive novelty they do not like to depend upon that plant for stock the following year; but as soon as the plant begins to grow freely they slip off a few of the first side-shoots, when yet hard and stubby, before they have acquired much succulence; they make these into cuttings, leaving the bottom buds, and striking them, and growing them; and though they do not bloom that season, they furnish a stock of fine, healthy, small tubers for the ensuing year.

Of *Bedding-out Dahlias*, I have seen several tried, and others recommended, that have answered with more or less success. The *Scarlet Zelinda* is a very fair thing, but the *Purple Zelinda*, though a poor thing, individually, in a florist's eyes, makes a splendid appearance either in a bed or row. Foiled as respects those I had carried home from such a distance, I applied to, and received a few from, Mr. Gardener last spring. I am almost afraid to speak of the temperature to which they were subjected, and the railroad pace at which they were

made to afford cuttings, and then got into rattling, robust plants before the end of May. I rather think we exceeded the *high* temperature mentioned by Mr. Beaton, the other week, for propagating soft-wooded plants in spring. At any rate, I had a row and some beds that were the admiration of everyone. The plants, on an average, ranged from fifteen to eighteen inches in height, were planted from eighteen inches to two feet apart, and were a dense mass of purple colour. So close and level were the flowers, for about ten weeks there was scarcely an opening left in which you could insert a couple of fingers. Many, on seeing them at a little distance, exclaimed, "whole beds of Cockseombs." They were, unquestionably, the finest feature in the gardens here, either in beds contrasted with yellow, or flanked with yellow in the row. I give them this prominent notice for three reasons: First.—It is a general idea that Dahlias, when extra stimulated for propagating, and being often and often cut in, do not do much good for that season. Be this as it may, these dwarf *Zelindas* were over stimulated, and no mistake, and every plant was smothered with bloom. Mr. Gardener would not believe scarcely that what he saw were the produce of what he sent. There is no difficulty in getting into a stock, therefore. Secondly—Many applications have been made for roots, which I have, so far, satisfied; but there are many more which, with a due regard to a home supply, I have been unable to meet; and several inquiries have been made by nurserymen and ladies as to where it is to be obtained for sale; and as I know it was mentioned in *THE COTTAGE GARDENER* years ago, I thought some of the readers might have a stock to dispose of. And thirdly—To draw attention to dwarf early-flowering Dahlias, as a new feature for masses in the flower-garden.

No doubt, just as in the case of the *Zelinda*, there are many that have been neglected, because they were never tried as a mass. In addition to the *Scarlet Zelinda*, there is a nice dwarf, Orange-variegated variety, *Miss Weyland*, from two to two-and-a-half feet in height, and in rather poor soil, was not above twenty inches last year, that would make no bad neighbour for the Red and Purple *Zelindas*, but with me it has been rather a miffy thing, and seems the only desirable, this season, in the Dahlia way, that will move the wrong way. We had a small flowering variety, nearly of the same colour, last season, (*Mrs. Labouche*), which might do for a taller bed. Our plant was from two-and-a-half to three feet high, and smothered with small flowers. I have mentioned that the flower of the *Zelinda* is such that a florist would never look at, but the habit might be retained, and the form be improved. I tried a little hybridising last summer, but did not succeed in getting a single seed. So compact and stubby were the plants, that they were almost the only plants in the garden that had neither pegging or supporting of any kind. R. FISIL.

THE CEDRUS DEODORA VERSUS THE CEDRUS LEBANI.

A CONSIDERABLE amount of botanical acumen has been used pro and con to find out whether these two remarkable trees are or are not the same species: some asserting that the Deodar is only a variety of the, in this country, more anciently known Cedar of Lebanon. I shall not enter into the merits or demerits of the arguments that have been advanced by the advocates of either opinion, sufficient for me, and, I opine, for all the readers of *THE COTTAGE GARDENER*, is the fact that no one, even the most superficial observer, will ever mistake the one for the other; and another no less weighty fact is, that seedlings of each tree always come

true, whereas, if the Deodar was only a variety of the Cedar of Lebanon, seedlings of the former would sometimes revert to a likeness of the original—a circumstance that I never could learn has even in the slightest degree been observed.

It is not, however, of such great importance, excepting in a botanical point of view, whether the one is a variety of the other or not. The grand points to be considered are, does the wood or timber of the Deodar last long?—Is it adapted for use, and is the tree hardy enough to bear the coldest of our winters?—and, lastly, will the wood be of as good quality grown here as it is said to be in its native country?

As the Commissioners of Woods and Forests are about to plant several thousands of the Deodar in our national forests, these questions are of great interest and importance to the people of Great Britain.

At the recent Horticultural Society's Meeting in Regent-street, both the Chairman (Dr. Royle), who resided for several years in India, and Dr. Lindley, spoke for a considerable time on this very subject, and as our readers are aware, thanks to my good friend, Mr. Beaton, that I was there, and he said "taking notes," I will try to give the substance of what fell from these two learned and scientific gentlemen, first stating, that most writers that have travelled in the parts of the Himalaya Mountains where the Deodars form extensive woods say that the timber is more highly valued than that of any other tree, and that well authenticated facts prove that timber from this tree has been used for the construction of temples built several hundred years and still remains good, and that the grain of the timber is close, compact, and easily worked, and is capable of a very high polish.

My second question—Is the tree hardy? is easily answered satisfactorily. We here have had it in cultivation more than twenty years in various situations, and it has passed through the ordeal almost unscathed.

The last question is more difficult, because it is a question of time, and can only be proved by analogy. Dr. Royle stated to the meeting that "the Deodar grows in regions from 5000 to 12,000 feet above the level of the sea, in which regions the weather is often very cold and varied," just such a climate as the hills of Derbyshire or the highlands of Scotland. Now, if the timber in the Himalayas in such a climate is excellent, why should it not be so in a similar climate in this country? The learned doctor gave it as his decided opinion that it would, and his opinion, he said, was confirmed in a letter he read from Mr. Wilson Saunders, of Lloyds, who stated that the wood of the Deodar was superior to the American Larch. The Doctor farther stated, that it had been argued that because the wood of the Cedar of Lebanon, grown in this country, is not so good as that grown in Palestine, that, therefore, the wood of the Deodar would also be inferior. This argument he considered to be erroneous, because ancient descriptions of the excellence of the timber of the Cedar of that country did not necessarily refer to it, but might refer to other cone-bearing timber trees.

Dr. Lindley judiciously followed up the remarks of the Chairman, and showed examples of the Cedar of Lebanon grown in this country, and pointed out some differences in the wood to prove the two trees were of a different species. The wood of the Lebanon Cedar is inodorous, whilst the wood of the Deodar is highly fragrant; a fact that any one in the room might easily prove by smelling at the two woods, for there was in the room a splendid specimen of the Deodar timber, a plank or board imported by the East India Company, which measured four feet six inches across, and eighteen feet long, and very nearly five inches thick. I could smell the odour of this wood very perceptibly, and the

Doctor said, when it was being planed the scent was very powerful indeed.

After all this evidence, I think the three questions I proposed to discuss are answered satisfactorily to every unprejudiced mind, and though I am now in years, I hope yet to live to see the day when many of our hills will be covered with this elegant, and, I may now add, useful timber tree.

There is a great similarity in this tree to our common Larch; so much so, that when it was first introduced many nurserymen propagated it by grafting on the Larch, but I have not seen any fine trees so treated. Seed is now imported largely, and, therefore, any other mode of propagating it, except by seed, is futile.

It is, however, like the Larch in one point, it will grow and thrive in exactly similar soil and situation suitable for that useful tree, and has the advantage of being evergreen, and thus far no insects have preyed upon it as they do on the Larch.

T. APPELBY.

THE ANTI RHINUM.

(Continued from page 461.)

General Management in the Border.—This paper will be the concluding one on the culture of this favourite flower—a flower more worthy of cultivation generally than many are aware of. I think, if any of our readers would pay as much attention to its culture, and the improvement of the varieties we already possess, as has been paid to the Auricula, Carnation, or Hellyheck, the care bestowed would be well rewarded.

As I said before, it has the advantage of being perfectly hardy, and will, in dry soils, live several years, if not allowed to bloom too long, or produce a full crop of seed. I have, in former papers, described pretty fully how to improve the varieties by seed; how to propagate them by cuttings; and, lastly, the best method to grow and exhibit them in pots; and now it only remains for me to describe its culture in the bed or border. There would be no objection to exhibit cut blooms in collections of eight or twelve dissimilar blooms, and three spikes of each variety would make a better show than only one. Growing in a well-prepared bed, these spikes of flowers would be finer than these in pots, at least, in length of spike, and most probably in the size of the individual flowers. Of course, there should be prizes offered for seedlings, and these should be shown separately, like all other seedlings.

To grow them well in the border, it should be duly prepared to receive the plants early in the autumn. Choose an open situation, but, if possible, sheltered at a distance from the north and west winds. Mark out the bed three feet wide, and if the situation be low and wet let it be well drained. Throw out the soil on each side of the bed, and place a layer of brick rubble at the bottom, three or four inches thick; upon that place a covering of the most convenient material on hand; thin turf, the grassy side downwards, is the best, but old thatch, or strawy litter, or even small twigs of trees would answer the purpose, which is to prevent the soil choking up the drainage. Then mix the soil, if tolerably good, with some well-decomposed manure, or vegetable mould, and some road scrapings, and sifted lime rubbish; the materials to be added amounting altogether to about one-eighth of the soil. If the latter is bad, remove it altogether, and bring in some sound fresh loam. When the materials are duly mixed with the soil, then cast it into the bed, using as much as will raise it six inches above the surrounding level.

If the cultivator has any kind of edgings the bed will look neater, and the soil will be kept quite distinct from the walk. Mr. Hogg's edgings answer this purpose,

perhaps, the best of any, but slate, or even boards, nailed at intervals to short posts, will form neat temporary edgings. Avoid Box, or any kind of living edgings, they are the receptacle or hiding place for slugs, &c., besides impoverishing the soil. The bed being thus prepared and formed, let it remain in a rough state for a month or six weeks to settle.

The best time for planting is the beginning of October. I consider this season the best for several reasons; first, because the plants are so hardy that no frost will destroy them in such a dry, well-prepared bed; secondly, the plants, if kept in pots through the winter, have the roots so cramped that they cannot spread out sufficiently when planted in the spring; and lastly, there are so many things requiring protection through the winter, that space can be ill afforded to any plants that do not need such shelter.

Choose a dry day for the operation of planting, and take care to have the plants tolerably strong at the time; then place them on the bed in their separate sorts; that is, if the cultivator has three or four of each variety, plant them altogether, to prevent confusion, allowing six inches square to each plant. Have some kind of labels to each sort, either legibly named in full, or numbered, commencing with No. 1, and so on, till the bed is full, the numbers corresponding with the numbers and names in the garden book. When all are planted, level the bed between the plants, and they will require no further care till the spring. As soon as the winter is passed, examine the plants, and press any down that the frost may have lifted up; clear away all weeds, and stir up the surface of the soil with a small fork. This will encourage the plants greatly by allowing the spring rains to penetrate the soil, as well as admitting the warm spring atmosphere to enter the soil more freely. As the plants advance in growth, it will be necessary to thin the shoots when they are too numerous. This thinning must be regulated in proportion to the strength of each individual plant; weak plants should only have two or three flowering shoots left, but strong ones may have four or five. Just before the blooms expand each spike should have a stick placed and tied to it to prevent the winds from breaking it off. When in full bloom, a covering of hoops and canvass, if handy, would greatly prolong the bloom, besides sheltering it from the sun and heavy splashing rains.

If it is desired to have a long season of bloom, cut down the first flowering spikes before seed is formed, then fresh flower-spikes will push forth from the base of each plant, and there will be a succession of bloom.

The finest flowers will always be produced on young plants; therefore, whoever wishes to excel in blooms should renew his bed and plants annually.

T. APPELBY.

PEAS FOR FIRST AND SECOND CROPS.

OF late a great outcry has been raised against White Peas of all kinds, unless it be some of the very large ones; this denunciation on the part of those whose province it is to direct public opinion, is, doubtless, in many instances right, but I do not think it is so in every one, for the anxiety to procure Peas at the earliest possible day ensures them a hearty welcome, whether they belong to the White or Green section to which the family is divided. Neither do I think, at this early period, when they are gathered without the possibility of an old one being amongst them, that they are so much inferior to their "coloured brethren;" but supposing they are, do they not possess a greater amount of hardihood and the other properties which enhance their value as "a winter standing crop?" This, I believe, will not be denied; but the next view which I take of their

respective merits may, perhaps, be questioned; it is this—supposing the green or blue section possess greater table attractions than the white, is the policy a bad one which reserves the best one until a beginning has been made? as it is well known the first are welcomed in with that hearty good-will that those fine points of distinction which characterise one variety from another are not regarded with such scrutinising nicety as they will be after a while; and the taste is sometimes so fastidious, that a great benefit is derived by having a road open to improvement, which could not be the case if the best was served first; but as I have all along advised the sowing of one or other of the best white kinds, of which the *Charlton*, *Kent*, or *Early Frame* is the parent for the first crop, but that the more esteemed ones at table might succeed them, it is needless saying any more on the subject than what is necessary to meet the individual cases of cultivators.

Peas, as an article for market, are largely grown in Kent and some other counties bordering the Metropolis. The plan there adopted is to sow them in drills, about two feet apart, in November, and about the end of April an intervening row of Swede Turnips is not unfrequently sown; this secondary crop is, of course, much trampled on by the picking and other work necessary with the first crop; still, it often struggles through, and a good produce is the result, but the Peas are, as might be expected, roughly handled; sticks, and other appliances common in gardens, are here disregarded, and the crop lying on its side is often roughly turned over to give up its treasure concealed beneath; this manner of doing it renders the latest kinds of little value for this purpose; but on the other hand, the very dwarf ones are as seldom grown either. The most productive ones are those which are about the size of the *Early Frame* and its compeers, but the kinds most grown are the *Kents* and the *Scimitar*. This latter is not much inferior to many of those with more pretensions; in fact, it may be called the parent of many of them; and how many "valuable kinds, with high astounding names," a bag of *Scimitars* may have furnished, is only known to those who have the mysteries of the trade at their finger ends. One thing is certain, the *Scimitar*, to this day, is a useful, good Pea; and though some have a better-filled pod, it is not to be despised for its accommodating qualities; but the amateur, who has but a limited space to dispose of for his Pea crop, and wants to make as much as he can of the ground it occupies, would do well to grow only the large or tall kinds, and by sowing them in rows of six or eight feet apart, Brocoli, or some other winter crop, might be planted between them, in July, in such a way as to occupy the whole space when the Peas are cleared away; and though the Brocoli plants may be much bruised and hurt by the trampling the ground receives, yet the season generally allows them time to recover themselves again, and good Brocoli, &c., is frequently obtained from ground that the preceding summer furnished abundance of Peas. This mixed-cropping-system is, however, not advisable in all cases; neither must the last sown ones be hampered by any intervening crop, for they will not be removed in time to allow the other an opportunity to rally and grow before winter sets in. Other crops, as well as that of the Cabbage tribe, are often planted in such places, many having their Celery shrouded by their Peas in summer; but this, as well as many other crops, is regulated by the circumstance of the case immediately in hand.

As it would not be just to close this subject without naming one or two varieties, which, in a usual way, may be depended on as good, I may say, that I have for some years depended on *Warner's Early Emperor* for the first crop, and the *Champion of England* and *British Queen* for the latter ones, and though I have

generally grown others as well, these three are the kinds I depend upon for a supply, and it is generally forthcoming. Observe, they are all sticked at the proper time, and are, therefore, in a condition to bear to the full extent of their capabilities. The ground they are sown on being deeply tilled, the roots have access to a greater depth than the droughts of summer is likely to penetrate, and thus one great cause of mildew is removed, that bane to the autumn Pea crop in the south of England, from which our brethren in the north are, in a measure, exempt. The Pea also likes a generous soil, and though fresh and green manures may create a grossness of habit when it is accompanied by a showery, growing season as well, still, a considerable amount of enriching matter may be added prior to sowing the crop, and as much in a liquid state after as the place will allow of, bearing in mind, that where much produce is expected, much manure ought to be given; and there are few things more deserving of attention, for none are more generally esteemed at table, than a dish of nice Green Peas, so that nothing must be denied them calculated to ensure their well-being.

It will have been noticed, by all parties who had Peas sown in the usual way last autumn, how much later they were this year than last; mine, sown in the middle of November, were scarcely through the ground at the end of January; while, last year, they were nearly a foot high at that time; but then they were entirely destroyed by the frost and snow we had at the end of February, so that the second sowing, made about Christmas, came in first; but the present winter is widely different from the last, the early part of it being very severe; while, since the second week in January it has been all that could be desired for benefiting the ground, which certainly works better than at any similar period for some years. However, we may have a trying spring yet, so that it behoves us all to be on the alert, and leave nothing undone now that can be done, for the time is fast approaching when a variety of duties are equally pressing on the cultivator, that every thing which can expedite future operations ought to be brought into bearing now.

J. ROUSON.

ECONOMY OF THE FARM-YARD.

(Concluded from page 464.)

In the foregoing observations upon this subject, reference has been made to the best method of managing the Farm-yards, as formerly constructed, both as regards the making manure, and the shelter for cattle; it has also been stated what the advantages are which have been secured by some of those most recently constructed upon improved principles. But it has only had reference to those yards and steadings where partial covering has been attempted, namely, when sheds or boxes have been recommended in connection with open courts or byres, as well as open pits or receptacles for manure, &c.

It is now my intention to allude to the most recent, as well as the most approved, style of Farm-steadings, and which, in my opinion, will be found in every respect the most desirable and the most economical. I refer to covered Farm-steadings, that is to say, buildings so arranged and covered that every animal usually fed at the farmery may be kept under cover, and all the manure made under cover also. Now, this new principle of building, as I shall call it, possesses several of the most important features in the economy of the

Farm-yard, for it enables the cattle to be fed and accommodated, during both summer and winter, under cover, thus enjoying the advantages of an equable and proper temperature, and at the same time a perfectly pure atmosphere, quite unknown to any other style of Farm-buildings. The manure also manufactured by the cattle, when thus fed and lodged, must be of first-rate quality, there being no dilution by rain-water, nor any evaporation by exposure to the sun and wind. The most appropriate plans which I have seen, for the erection of buildings of this description, are those set forth in the twenty-third number of the Journal of the Royal Agricultural Society of England, by Mr. Fisher Hobbs, and by Lord Kinnaird; and it would appear, from their statements upon the subject, that a saving of ten per cent. in the cost of erection is effected, as compared with former erections upon other principles; and this may be easily conceived, when it is considered that the roofing and outer boundary of the buildings are the most expensive part of the affair, the internal fittings being very simple and cheap, although very durable and effective; and it is in these internal barriers or divisions between the boxes, stalls, or cattle pounds, where the economy is obtained, for in buildings of another principle, the boundary walls or division of almost every compartment of the steadings involves the necessity of a wall, or fence, of a description necessary to afford warmth or shelter to the animals. I am not, however, wedded to the opinions of other parties in this matter; for I believe that the practice, as set forth in connection with the buildings above referred to may be much improved, particularly in the management of the manure; for instance, it is stated that drains are constructed for the purpose of carrying off the liquid-manure from the stalls, boxes, or cattle courts; but in case the principle of box accommodation was carried out entirely through the whole concern, there would be no liquid to drain away, it would be all absorbed by the earth placed at the bottom of the boxes, sties, &c.

Now this brings me to an important point;—if box-feeding, wherein the manure is allowed to accumulate under the animals, is the best and most economical system, why not carry it out in all its entirety; for in a covered home-stall there is no lack of room, nor is there an opposing obstacle of any kind. At any rate, I contend, that every animal ought to be accommodated in such a manner that no liquid-manure could escape or require drainage, and that the cattle, whether fattening beast, or dairy Cows, as well as Pigs, are best provided with boxes which have earth at the bottom, and littered with straw as required. In the case of Sheep, when house-fed they may be kept upon spars, or open boarded floors, or, otherwise, in littered-yards. The Horses, also, may be allowed boxes upon the above-named principle; but in case these are objected to, as they are by some, although, I believe, without good grounds, they may be treated as described in the former part of this paper, by earth-floors to the stalls, which will absorb and render quite innocuous the

liquid-manure. The system will then be carried out, and thus enable the whole of the animals upon the farm to be fed in a covered homestead, if required, with the full advantage of securing health and well doing for the stock, or breeding and working animals, and the further gain of obtaining the largest amount of meat in return for the food consumed; and at the same time securing the greatest possible amount of manure of the best quality, without detriment or risk to the health of the animals.

I cannot leave this subject without alluding to the superior crops, both of roots and grain, which have been obtained by the application of dung made in covered home-stalls, as compared with those raised from manure made in an ordinary Farm-yard. This result, however, might have been anticipated and expected apart from actual experiment.

In concluding this article, I beg to state, that I have adopted for several years the system of using earth at the bottom of the yards, cow-stalls, pig-sties, &c., and wherever manure has accumulated; and I have been often met with the question, "Where do you obtain sufficient earth for the purpose?" my answer is, that it is part of my farm economy to provide it at all seasonable times, and take it from all parts of the farm where objectionable accumulations have occurred.

I have seldom seen a farm where loose earth could not be readily obtained, the only exception which I know of is upon high chalk or stone-brash soils, and even in these cases, considerable quantities of earth will accumulate upon the borders of fields, the removal of which would improve the fences.

Upon farms in general, particularly in enclosed districts, large quantities of earthy materials are constantly collecting under the hedges, and instead of being burnt into ashes, as is a common practice, they had far better be removed, at leisure opportunities, to a heap where they would rot and become mellow, for the uses before-mentioned. I must further observe, that it is only necessary to make the use of this earth a part of our system of management, and we shall neither want materials or time to collect it. JOSEPH BLUNDELL.

HAMBURGH FOWLS, AS RECENTLY EXHIBITED.

THE comb, ear-lobe, and colour of the legs, being the main common properties connecting the Pencilled and Spangled Hamburgs, while in several important points a marked distinction exists between them, it has occurred to us that these varieties would be better arranged if their "*markings*" rather than their "*colours*" always determined their classification. By such a system we should have Golden-pencilled and Silver-pencilled following each other, and then the Spangled of those colours in their relative positions.

That any relationship can be traced between the Spangled and Pencilled varieties will hardly, we think, be asserted, and it is certainly contradicted by the produce of these birds when crossed with each other failing to present any resemblance to the plumage of either parent, a bird of dingy indistinct colours being the usual result of such an alliance. The common properties already alluded to, and a desire to avoid the confusion of a host of synonyms,

evidence their position under the general head of "Hamburghs," but there is even less reason to argue for any connexion between them from the circumstances known to us of their original habitat, than from plumage or other characteristics. The Spangled birds, indeed, are emphatically English, while the Pencilled, although extensively kept in this country, are imported from Holland and Belgium in large numbers, among which, according to the testimony of one of our most extensive dealers, not a single Spangled specimen has passed into his hands. For these reasons, therefore, we should prefer the classification of these fowls as "Pencilled" and "Spangled," and to let the colours of each of those breeds form their respective sub-divisions. As they now stand in many prize-lists, after viewing the Golden-pencilled pens, we pass to the Golden-spangled specimens of a totally different character, then return to the *fac-similes* of the first-named birds, colour alone excepted, concluding with a repetition of No. 2, with the same excepted point.

In the *Golden-pencilled* class, the result of the past year can hardly be termed satisfactory on a general review; a few pens of great merit, such as appeared at Leeds, and one or two elsewhere, would be the only exceptions to this criticism. In respect of the *Silver-pencilled*, our opinion of those shown in 1853 is to the same effect.

The Spangled birds, however, deserve more honourable mention, and here it may be fairly said that a step in advance has certainly been gained. At Birmingham, for instance, there were several excellent pens of *Gold-spangled* birds, and the same at Doncaster and Leeds; these, however, are the districts where we should most expect to find them. But in the south of England there still remains a wide interval between the specimens usually exhibited and the models we would hold out for their breeder's imitation. The perfect character of the spangle in the male birds of this variety is of difficult attainment, and many a pen has, doubtless, been disqualified on account of the dark streaky-breasted cocks that have been shown with good hens. Among other means to secure the distinct development of the spangle on a clear ground-colour, an infusion of Gold-laced Bantam blood seems to have been had recourse to. But not to dwell on the loss of size consequent on such a cross, the characteristic Hamburgh-tail has, of course, suffered, and hence the objections justly entertained by many against the square hen-tailed birds that have lately appeared. The absence or deterioration of an acknowledged characteristic in any family of fowls cannot thus be compensated, and a hen-tailed Hamburgh, therefore, has no charms in our eyes. Let the spangle, by all means, be perfect; but however good, we cannot accept it in lieu of the full sickled-tail that so well suits the erect carriage of a good Hamburgh, whether Spangled or Pencilled.

In the *Silver-spangled* Hamburghs our expression of commendation must go further. The Northern and Midland Exhibitions were remarkably good in this respect, and left little to be derived in point of form, feather, or condition.

Hamburghs, as a family, have certain precise rules of arbitration on their several merits, which, comparatively speaking, have been only lately applied to many of our other fowls. The decision of judges, therefore, have, in this instance, perhaps, been as severely scrutinized as usually happens in any department of their labours. One judge is charged with an undue affection for a well-bronzed tail; another is thought to cherish an unfair regard for the markings only; comb, ear-lobe, and figure also are said to be severally reckoned as the most essential points in the eyes of others; and, consequently, more availing frequently follows their decision in this class than elsewhere. We do not think, however, that such charges have been generally founded in fact. Judges, we believe, have endeavoured to balance all competing points; and it is rather in the conflicting pre-judgment of individuals on favourite properties that such remarks have originated. The former, indeed, might allege on their behalf that nowhere, commonly speaking, does less care appear to have been taken in making up and matching the several pens. On more than one occasion, indeed, have three excellent specimens in a pen been deprived of their chance by the presence of a faulty companion, and the selection of a more even pen is then incorrectly regarded as a preference of all the individual birds.

In a class of fowls so widely distributed throughout some parts of England, it may fairly be required that there should be high merit in every single specimen in a pen to which the honours of a prize are to be assigned; and such faults as a bad ear-lobe, lopping comb, imperfect marking, tail unsilvered in the male birds of the one, and unbronzed in those of the other Pencilled variety, legs of any colour but blue, and the presence of a fifth claw, are most properly held to disqualify the whole lot, although present in a single member only. And yet, strange to say, such disqualification, on such grounds, nay, even occasionally where more than one of these defects has been apparent, has been considered just cause of grievance by a disappointed exhibitor.

Hamburghs have, perhaps, been thrown somewhat in the shade of late by the greater popularity of fowls, either of recent introduction, or of such as Dorkings or Spanish, which, although of common occurrence, have received such great improvements at the hands of experienced breeders. Hamburghs, however, possess such unquestioned merits, in an economical point of view, and are, moreover, suited to so many circumstances where the latter would be ineligible, that there can be no cause to apprehend such remissness on the part of the poultry-keeping community as would forbid the speedy alteration of the points in which many of them have of late appeared deficient. The Birmingham Committee, indeed, have allotted no less a sum than £18 for their encouragement in Bingley Hall in December next, and we are much mistaken if such a recognition of their value, and the free expression of what has hitherto been unsatisfactory in their appearance at Exhibitions, will not render their reviewer's task another season not only more agreeable to himself, but also more laudatory to his subject.

GAUNTLET PELARGONIUM.

THIS is the first one, and the last out, in the market for cut flowers, and is also one of the best bedders for early summer, or late autumn, but whether it is as good for the height of summer, I cannot say; probably it is, if it does not rest awhile after the first bloom is over, as most of that section do. The *Queen of Roses* is a strong bedder, and as full of flowers as can be, but there is only one way, that I know of, to cause it to flower without interruption the whole summer, and down till the frost comes, and that way is very likely to do for the *Gauntlet*, and some others of the old greenhouse kinds, which is the reason why I intrude on the Editor to get this inserted just at the proper moment. Any one who has a stock of young *Gauntlets*, or *Queen of Roses*, or of *Priory Queen*, or of any other Pelargonium which is known to flower pretty freely in the autumn, has only to forego the chance of an early bloom to secure a constant succession of bloom, as bedders, for the rest of the season. This is managed by having the plants stopped between the 20th and the end of March, and after that to keep them as cool as possible till the middle of May, when they are fit to turn out into the beds or borders along the walks.

Young plants, struck last autumn, are the best, and the only ones by which I hit on this plan, after a great many trials with different sorts. If they are stopped before the 20th of March, and are kept in a good greenhouse, they come into flower in the middle of June, and rest a month; but if you can so manage as to keep them from coming into flower till the very end of June, or the first week in July, they will flower continuously after that to the end of the season, and very likely old plants would do the same. I have stopped several old sorts every fortnight, from the middle of January to the end of April, several years in succession, and kept a register of the whole, and those that I stopped about the last week in March did the best. That was my period to stop, for the last time, all the plants I needed for two beds of the *Queen of Roses*, which I wanted to fill early in July, after a crop of Annuals, and that is the best time to stop *Gauntlet*, on the supposition that it rests a while after the first flowering. It will make a bed as gay as any Pelargonium I know of that class; the colour is between rose and scarlet.

D. BEATON.

POLAND FOWLS.

Will you kindly allow me to make a few remarks on your article in *THE COTTAGE GARDENER*, entitled "Poland Fowls as recently exhibited." Your arguments, at the commencement, having reference to the classification under one head of what were formerly known as Tuffed Hamburgs and those birds known as true Polands, are, to my mind, so satisfactory as to need no comment; as also your caution to exhibitors who are so fond of *improving* upon nature in the combs and crests of their Poland Fowls; and for their own credit's sake, it is to be sincerely hoped they will profit by the advice given them.

The observations I intend to make (with your permission), apply to that portion of the article relative to the want of hardihood and *profitless* character of the Poland Fowl. Before going any farther, I must inform you that my experience of them has hitherto been confined to the *Silver* variety, and a reference to the prize lists of the principal shows in the kingdom, from last June to January, will show that my birds are no mongrels, they having attracted the favourable notice of the Judges, and were successful no less than ten times in that interval. I call attention to this fact, merely to show that they may be taken as a fair sample of their class; and I can safely say, that as exhibition birds they are equal in point of endurance to any that were ever in a pen, having stood the wear and tear, the long fastings, and feasting to repletion—this day food of the most stimulating character, and the next day nothing—in addition to being confined, in some instances, forty-eight hours in the travelling hauper; and sometimes, as in the case of the Surrey and Birmingham Shows, packed up and sent from one place to the other without seeing home, yet my adult birds have never shown the slightest trace of indisposition or loss of appetite, in fact, were never one wit the worse for it. I cannot say the same of Dorkings or Cochins, which have both suffered more or less in going through the same ordeal from which the Polands came scatheless; the only other birds which I found stood it as well were the Brahmans, which I believe to be a much hardier race of birds than the Buff Cochins; both the latter and the Dorkings were usually scoured for two or three days after coming home: the Polands never so.

As to feeding, run, and general treatment, I fearlessly assert, *that with me* there has been less illness (and certainly not one jot more care taken of them) than among my other fowls; they are fed the same, roost the same, are quite as much exposed as the rest, and, as I have before stated, with the best results. With reference to their character as profitable fowl—in this, I think, they will also bear a more favourable comparison with many of their rivals than you are inclined to accord to them. As egg producers, in my opinion, they may fairly vie with their more favoured compeers the Spanish. I did not register the number of eggs produced from a given number of hens last season, but am doing so now, and, should you deem it worth your acceptance, will give you facts, which will, I fear not, bear me out in the opinion here expressed; their eggs are remarkably fine, and I will also weigh some of them, and when I send the number will also send the *average* weight, because, although an egg is an egg, yet, if ten Poland eggs weigh as much as twelve Cochins, which I think they will, they would, in a great measure, make up for the extra number that the latter produce.

My Polands, last season, laid up to October, and some of them commenced again the first week in February, and it must be remembered, that they continue to lay without intermission throughout the season, never becoming broody; this may, by some persons, be put down against them, but now that we have the Cochins, who will sit as many times in the season as you like to let them, it will only be necessary to keep three or four Cochin hens to have a constant succession of Poland chickens the year through.

As a table fowl (and here I only speak from information), I am told that the flesh is more delicious than that of the Game Fowl. I will grant the chickens are somewhat difficult to rear, and that they are not of such vigorous and rapid growth as Cochins, but the advantages I have already enumerated—their great beauty in plumage, symmetry, and carriage—shall surely be allowed as some set-

off against that one argument in their disfavour, and which I hold to be the only bad quality they possess, from the size of the crests (in good birds) the *range* of vision is necessarily very narrow, consequently, I find no difficulty in confining them within the most circumscribed limits, in fact, the partition which divides them from Brahmans and Cochins in my yard, is, in some places, little more than two feet high, but they never attempt to fly over. I am not sure that the difficulty in rearing the chickens does not lie with the breeder; it is not improbable that they require some mode of treatment as yet undiscovered; but, by practice and perseverance, I think we shall be able, in time, to rear Poland chickens as easily as any of their more fortunate brethren: at any rate, I mean to try. I am induced to say this, from the fact that all my Poland chickens were as vigorous, as hearty, as good feeders, and got on *as well*, as any birds could be desired to do till two months old (at which age we usually think the danger past); about that period, and in many cases older birds, I had the mortification of seeing the most beautiful chickens, day after day, drooping their wings, and in a short time making their exit from the world of chickendom; however, I persevered, tried various schemes and modes of treatment, and at last, with some very late chickens, was tolerably successful, rearing six out of eight hatched, now all alive and well. I will let you know what success I have this season, and also my mode of treatment, whether beneficial or otherwise, and should be glad if some other Poland breeder would do the same, my object being the attainment of truth and mutual benefit.

In the same paper, in answer to a correspondent, you say that Polands are much addicted to the habit of plucking and eating each other's feathers; to my sorrow, some of my best birds have suffered from this species of cannibalism, *but in no one case* has the perpetrator of the mischief been one of their own kind, but it always has been the work of a Cochin or Dorking. I do not, for one moment, mean to doubt what you say on the subject, believing you have good grounds for your opinion, or you would not have given it, but only intend to show, that in my experience, the Polands are the victims and not the perpetrators of the mischief.—P. JONES.

[Your promised communications will be most acceptable. Any one who will favour us with facts confers a boon upon us and our readers.—ED. C. G.]

SUGGESTIONS FROM THE GARDEN AND THE FIELD.

By Cuthbert W. Johnson, Esq., F.R.S.

(Continued from page 461.)

THE CHIEF SUSTAINERS OF LIFE.

THE way in which the gases of the atmosphere are made subservient to the demands of animal and vegetable life betrays the same beneficence, and the same wisdom, that is apparent in the other works of the Creator. Composed of only three gases, one (the carbonic acid gas) incessantly absorbing by plants, who as regularly emit another (oxygen gas), it is evident that the proportion of these in the atmosphere, would, without some countervailing mode of supply, be speedily and materially altered, but this is prevented by all breathing animals absorbing the very gas which plants emit, and emitting the very gas which plants absorb.

The delightful freshness and sense of pleasure experienced by breathing pure air is known to every one; yet breathing, being an involuntary action, is one of those of which we rarely pause to consider its advantages and its pleasures. It is only a person in a confined room, of which the atmosphere is contaminated with unwholesome emanations, that is really sensible of the advantages and pleasures of freely inhaling a pure atmosphere of the same unvarying composition as created and regulated by the wisdom and beneficence of its Divine Author.

That this happy uniformity in the chemical composition of the atmosphere is preserved in all places, and in all seasons, has been ascertained by many comparative chemical examinations. Atmospheric air, in fact, has been analysed, as obtained from various parts of the earth, from the

summits of mountains, in populous cities, and from the surface of the ocean, far away from land—but its composition was always found to be the same. The supply of its gases, therefore, is always equal to the demand made upon them by the animals and vegetables which tenant the earth.*

Let us, however, proceed in our examination of some of the chemical phenomena which attend the sustenance of animal life from its first existence, and in its progress to maturity. Let us see how the elements are made subservient to our comforts and our enjoyment.

Follow a young animal from the period when it first inhales the breath of life—when the atmospheric air first rushes into its lungs. Witness the wonderful adaptation of those lungs to the separation of the vital portion of the air from that which is to be rejected—the nitrogen, which dilutes and modifies the action of the oxygen gas; a gas the action of which upon the lungs would otherwise be too powerful. Mark the chemical composition of the muscles, the blood, and the other fluids of that body, all intended, and, by their peculiar chemical composition, adapted to the nourishment of the animal. Notice the bones, placed in the midst of those muscles, lubricated by various fluids, which if those bones were composed of soluble substances would infallibly dissolve them. Notice, I say, the chemistry of those bones—how the phosphate of lime, and the carbonate of lime, two salts which, when united with the cartilage of bones, are totally insoluble in the fluids of animal bodies. See how wretched is the plight of those rickety children from whose bones these salts are withdrawn; and yet, how rare is it to find these earthy salts removed from the bones, even by the effects of disease; such a withdrawal is ever an exception to the rule, which we notice for its singularity. Is not this constitution of bones evidence of the most exalted wisdom, and the most Fatherly benevolence?

Examine still farther the progress of the young animal's life; the power imparted to it of enjoying the light of heaven; the sweet flower-scented air; the pleasures of warmth; of satisfying its hunger; all of which might have been received, had God so ordained, without the least pleasurable sensation. Reflect on the plight of those who have been by accident or by disease deprived of their palates. They still eat, it is true; hunger occurs as usual, but the pleasure of eating is gone with the power of taste. On the contrary, the atmosphere might have caused irritation and pain when breathed; a very slight difference in the proportion of the gases which constitute the atmospheric air might produce a mixture strangely differing in its action on the lungs. In fact, by considerably increasing the proportion in which the oxygen of the atmosphere is united with its nitrogen, a corrosive acid, the nitric, or aquafortis, is the result. The very proportions of the ingredients, therefore, were regarded so as to constitute that precise mixture the best adapted to the wants and the pleasures of animal life.

As soon as the young animal begins to digest its food, so soon does it begin to increase in size, its muscles enlarge, its bones extend. The chemistry of these enlargements, as far as we are capable of understanding them, is full of interest. The muscles are composed of only four substances, carbon, oxygen, hydrogen, and nitrogen; the food given to the babe, in its milk or its bread, contains all these. They are digested and assimilated with almost unerring regularity, in a way we can neither imitate nor comprehend.

The presence of the totally insoluble salt, the phosphate of lime, or bone earth, both in the milk of animals, and in the flour of wheat, is most remarkable. It is certain that its presence is essential to the growth of the young animal, to supply the solid matter required for the enlargement of its bones, and it is equally true that God has provided that supply in its mother's milk, and in the bread it eats; but how the phosphate of lime is absorbed from the soil by the green plant of the wheat, how held in solution by the milk, are facts which can only be classed with the many other unexplained phenomena of organic chemistry.

The moment that organised beings existed on the earth,

it became necessary to combine with their substances a certain portion of heat. Animals, in fact, had to be furnished with the power of generating, or, at least, developing a certain portion of heat, for without that supply the insensible vapour of the atmosphere, so essential to the existence of vegetables and animals, could no longer exist. Life would be immediately extinct; the fluids of vegetables and animals become solid; the earth, in fact, tenantless; the ocean a quarry of ice. To place a living body in a temperature and in a medium in which he could continue to exist, required a foresight and an Omniscience of which we, who only reason from the results of experience or comparison, can form little idea; and we are, indeed, not in the least degree aided in our endeavours to grasp the difficulties of the case by concluding, with some very few credulous persons, that all this extraordinary arrangement of organised life originated from a miraculous accumulation of chances.

But heat is not the only imponderable which betrays the wisdom and foreknowledge of the Deity. Light, too, operates in an essential degree upon organised beings. In its absence, plants lose their green colour, their fluids become more watery, they no longer contain their usual proportion of nutritious ingredients, they cease to absorb the carbonic acid gas of the atmosphere. Plants, therefore, were evidently created with a designed reference to the medium in which they were to vegetate; their health, their green colour, their nourishing properties, as regards animals, were all made with a reference to the medium in which they were destined to dwell. As relates to animals, the construction of their bodies bears evident testimony to the enjoyment they were intended to derive from the presence of light. The yellow, sickly appearance of those persons who dwell in the deep back-woods of America, or in other places where light is only present in very diminished proportion, is generally known. That light also effects the healthy tone of the human body, is well understood; the gloom of darkness, the cheerfulness and exhilaration produced by the glorious light of Heaven are almost household proverbs.

That light was intended for the use of animals, in its mechanical properties, the existence of the eyes of all animals proves; for without light, in what would consist the use of eyes? A thought will readily suggest itself to the mind of the intelligent, when dwelling upon the phenomena of light, what a chaotic world ours would be without its vivifying presence. Its importance is not confined to its most obvious properties, the assistance of vision. Without light, many other chemical changes, besides those to which I have already alluded, would not take place at all; "the blythe blink" of our firesides would be unknown; almost all vegetation would expire, and man would be as ignorant, as degraded, and less powerful than the brutes around him. There is no doubt but that light acts upon all living creatures as a gentle, but enduring stimulus. Who does not feel more active in body, more vigorous in mind, amidst the brightness of summer than in the darker seasons of the year?

A dismal climate, a dark November and melancholy, are associated in our language; while widely different scenes rise to the imagination with the name of bright summer skies. Mr. Stuart, the celebrated pedestrian tourist, has recorded, that he never was so healthful, or in such spirits, as when in a high northern latitude at that period when the sun sinks not below the horizon for successive months. Yet the importance, the necessity, the blessedness of light, its adaptation to the physical welfare of the whole creation, is seldom reflected upon, notwithstanding that this seems, as it were, held up to our attention by the sublime command which preceded the creation of any organised being. "Let there be light, and there was light, and God saw that it was good."

(To be continued.)

CANKER IN PIGEONS.

I HAVE frequently had Pigeons attacked with canker in the mouth and throat, and have adopted various methods to cure it, but with little success, until I tried the following.

If the Pigeon has it very severely, the canker is loose, and a portion of it may be removed, which is advisable as

* This fact may be used as another corroboration of the truth of the sacred historian's statement, that vegetables and animals were created about the same period; for otherwise the consumption of carbonic acid gas by plants, without the presence of animals to restore it, would speedily have exhausted the air of this gas—a gas so essential to their vegetation.

much as possible, and then to apply *Gipsy-gum*, which may be had of any Chemist.* It should be used by a feather being dipped in it, and then well rubbed inside the mouth and throat, and repeated *twice a day*, until a cure is obtained; which, with care, may soon be effected. Great care should be taken to remove all birds affected with it, as it is highly contagious.

I have no hesitation in recommending the above, as I have frequently tried it, and always with success.

Your Correspondent, C. H. B., at page 130, No. 268, states that he has kept fancy Pigeons for years, and never but on one occasion knew them to eat *green food*, which, I should suppose, was caused by their not having the *chance* to get at it. I have kept them for many years, and always found them to be very fond of Cabbage leaves, and of almost any sort of garden stuff.

If my birds have been confined to the *aviary* for a few days, through high winds, or other cause, I have noticed them, on being released, fly straight to the garden, and seem to enjoy themselves wonderfully with a little cabbage. I should recommend all fanciers who do not allow their Pigeons their liberty to supply them with green food, for I consider it conduces greatly to their health.

I know that many persons keep open pans of *water* in their *aviaries* for the Pigeons to wash, which I strongly object to. I frequently allow my Pigeons to have a bath about once in a fortnight, for a few hours, but on no account would I let them have it regularly, as I consider that it causes many *diseases* in the birds, owing to their drinking the water they wash in.—ORIS.

HARDY BORDER PLANTS.

(Continued from page 446.)

OMPHALODES VERNA.

VENUS'S NAVALWORT.

THIS pretty little early-flowering plant belongs to the natural family of Borageworts, and its little light blue blossoms look so much like the true *Forget-me-not* (*Myosotis palustris*), which grows so plentifully by the sides of our river banks, that this plant is often called by the same remembrance-asking name. It is true, both plants belong to the same Natural order, and the blossoms of each are extremely beautiful, but the *O. verna*, of course, is a very different plant to the other, and delights to be grown in the warm sunny borders, or upon a rockery, where it seems just in its element. It is of rather a wandering or stoloniferous habit; therefore, when grown as a bunch plant in the neatly kept flower-borders, that is, where the plants are kept as medium sized bunches, at proper distances from each other, then this is a plant that will often require to be taken up, or carefully separated, leaving the best portion of the bunch to form the future plant.

This is one of those plants that should not be chopped round for the purpose of leaving just the centre part to remain, for in this, that happens to be just the worst part of the plant and being thus chopped all round is placing the plant, in so much the poorer condition, besides taking away just all the best flowering parts, which are the points of its stoloniferous crowns.

When these plants appear to us to be too large, we take up the whole plant, well work up the soil, either change it, or add a little fresh, and divide the plant, taking care to plant again one of the best side pieces. This we do in the spring months, at the time we may be dressing the borders, and whether it is in bloom or not.

This delightful little dwarf plant is a native of South Europe, and was introduced to this country in the year 1633. The whole herbage of the plant is of a pale green colour; its leaves stalked and egg-shaped; and the light blue flower produced in little clusters from the latter end of February to the end of April. Being so dwarf it is a front row plant in the borders. T. W.

* Our correspondent must mean *Ægyptiacum*. It is an old remedy for ulcerations in the mouth or throat of animals. It is thus prepared. Powdered verdigris, half an ounce; honey, two ounces; vinegar, eight ounces. Boil them together slowly in an earthen pipkin for ten minutes.

SPANGLED HAMBURGH FOWLS.

As an old breeder of the Spangled Hamburgs, I was glad to see we were beginning to have a little discussion upon the points of excellence of this much-admired and justly popular breed. As a frequent exhibitor of the Hamburgs, I feel the same anxiety your correspondent does (who designates himself an admirer of the saddle-feathers), that some definite rule ought to be agreed upon by the managers of the various societies, and that after coming to a decision as to whether we are to have hen-feathered cocks, or those with the long saddle-feathers, that it would be well to insert in the rules, that in such a class the judges would be requested to award the prizes only to hen-feathered, or saddle-feathered, as the case may be decided upon; by that means exhibitors would then know what to show; and, as we are rarely in possession of information as to who the judges are to be, and, perhaps, even then not knowing which they prefer, we are at a loss to know what to exhibit.

Your correspondent is misinformed in saying, that in Yorkshire none but those having the saddle-feathers would be considered pure. I can say, that nine out of ten prizes awarded to the Golden Spangles, in Yorkshire, are given to the hen-feathered. The hen-feathered Silver Spangles are more uncommon, and have as yet been but very little exhibited in Yorkshire. A first prize in Silver Spangled chickens of 1853 was awarded to a pen with a hen-feathered cock at the late Manchester show; and although an unsuccessful exhibitor in the chicken class, I must confess a better pen of birds I never saw.

As a breeder, I decidedly prefer the hen-feathered, the cock being spangled all over the body, similar to the hen, but the colours much more brilliant. Some of your correspondents think the eggs from the hen-feathered not so prolific as from the saddle-feathered. I do not find that to be the case from my experience. I am aware good hen-feathered cocks are much more difficult to breed than the saddle-feathered ones, but I do not think that is a reason why we ought to discard them. The very high price that some of the hen-feathered cocks have been sold for proves the estimation they are held in by the fanciers of this breed, and I think we need no further proof of their popularity than that. Much has been said about which breed is the most profitable. I am inclined to think none are more so than the Golden and Silver Spangled. The quantity of eggs laid by them in a season is unequalled by any other breed, and I have no doubt we shall long see them cultivated, when many of the new and worthless varieties are extinct.

JAMES DIXON, Bradford, Yorkshire.

THE AUSTRALASIAN BOTANIC AND HORTICULTURAL SOCIETY.

INTENDING emigrants will be pleased to see that Australia has institutions similar to those of "the old country," and in the list of Roses exhibited upon the occasion we now report, they will see none but those with which they are, or may be, acquainted in our own Rose Gardens. The meeting was at Sydney, on the 3rd of last November, which is the height of summer there.

"We were delighted to be present at an attempted resuscitation of the monthly meetings of this Society, which were originally intended for the display of specimens, for discussion on the subject and the specimens brought forward, and for the receipt and reading of papers forwarded to the secretary. A vigorous attempt is now being made to carry out these good and judicious intentions of the founders of the Society, and the meeting of yesterday, though but thinly attended, from a want of knowledge of the attractions it presented, is an auspicious omen of future success.

"The secretaryship of this Society has at length fallen into hands which will be responsible for neglect and maladministration of its duties, and in congratulating Mr. Catlett upon his appointment, we can only say, that should he succeed in working up the Society to the position it originally aimed at, and which it ought to hold, he will have done good service to the citizens of Sydney, and to the colony at large.

"The meeting was prudently, perhaps necessarily, confined to the exhibition of flowers and the awarding of certificates; but we hope that succeeding meetings, though adorned by these pleasant illustrations, will take a larger scope. What florists and botanists want here is not only the result, but the process by which that result is arrived at.

"Written documents, carefully got up by cultivators, would, perhaps, be more useful than oral descriptions—at all events, they would provoke more exact enquiry and more minute discussion.

"The monthly meetings will be the true tests of the perfection to which the cultivation of flowers in their respective seasons has arrived, and we hope, in future shows a somewhat more discriminating spirit will be evinced in the awarding of testimonials. Where all is good it is difficult and unpalatable, no doubt, to draw distinctions; but wherever excellence prevails, let it have its due.

"The main feature of the meeting of yesterday was the exhibition of Roses—and certainly our flower shows hitherto have afforded but faint indication of our capabilities in this line. A grander collection of the different varieties of this beautiful flower could hardly be presented in any part of the world than that which met us yesterday. The extreme wetness of the season prevented some of the more showy specimens being brought out in first rate order; but careful cultivation was evident in each collection.

"The largest collection was from the garden of Thomas Woolley, Esq. (Creswick, gardener), and consisted of fifty-two varieties, viz., Letitia, Victorie des Hybrids, Cloth of Gold, Virgil, Multiflora elegans, Queen, Dark marbled, Viole odora, Zandro, Amie Yibert, Allenianna, Lucida duplex, Gloire de Rosame, Louise Philippe, Indica alba, Provence, Emile Courtier, Boule de Nanteuil (particularly beautiful), Delphine, Glory of the West, Annie Bluze, Dupetit Thouars, Sully, La Tortarelle, Psyche, Henri Plantier, Fortune's yellow, Particolored China rose, Fulgens, Angélique (moss), Columella, Shepherd's incomparable, Yellow Banksia, Victoria modesta, Wax, Roi de Craquoise, Kate, Alice, Atoninas, Alexina, Superba, Green's musk, York and Lancaster, Madame Deprez, Shepherd's Ne plus ultra, Indica Lutea, Tagliani, Duc de Guiche, Carnation, Duchesse de Berni, Ferrox, Nonpareil Multiflora.

"There were five other collections exhibited.

"The specimens apart from the Roses were few. There was a beautiful *Gladiolus splendens*, and *Gladiolus Mortii*, from Mr. Mort's garden; the latter very beautiful; also a beautiful flower not often exhibited, *Epidendrum macrochilum*.

"Mr. Guilfoyle had twenty-four splendid specimens of *Gladiolus*, which did credit to his skill as a cultivator—they were all Hybrids. There was also a beautiful specimen of *Amaranthus Johnsonius*. Some very beautiful *Gloxinias*, from the Government Gardens, together with a specimen, in flower, of the *Gardenia Stantiana*, (the first time of its flowering here); and a very elegant *Echitis*.

"Medals were awarded to each of the collections of Roses, and certificates to Mr. Mort, for his *Gladiolus Mortii*, and his *Epidendrum macrochilum*, and to Mr. Guilfoyle for his collection of *Gladioli*."—(*Sydney Herald*.)

NEW BRUNSWICK, NEW JERSEY.

Extract from a Letter, dated Feb. 16.

"THE price of provisions here is much greater than usual. Corn is now selling at 95 cents a bushel of 56 pounds. Potatoes at 1 dollar 25 cents; flour at 5½ cents a pound; butter 25 cents a pound. All these articles have sold within a year or two for half the amount quoted above. Beef, mutton, and pork at 13 cents to 18 cents a pound. The wages of labour have increased nearly 25 per cent. A good horse cannot be had for less than 200 dollars; and a good cow for 500 dollars. We have had rather a mild winter thus far; some quite cold days; thermometer 2 degrees below zero, and many slight falls of snow. Our river and canal have been twice frozen over to the thickness of 8 or 10 inches, which has enabled the people to fill all their ice-houses, and all are well supplied. We have had some very

good sleighing, but the roads at present are almost impassable. This month has been very mild and wet, and we consider our winter nearly at an end. I visited the great exhibition of poultry in New York, yesterday, with Mr. — and some friends. The papers state there were 4,000 head, but I cannot believe it, though I never saw such a number of all sorts, from a Bantam as small as a meadow Lark to a Shanghai as big as a Turkey. Every species of fowl was there, and all in fine condition."

POLMAISE HEATING.

BEING a constant reader of your valuable Journal, I observed in the two last monthly numbers a revival of the much-abused system of the Polmaise method of heating pits, greenhouses, &c. &c.

Not being a practical gardener, but merely a devoted student, and fond of every improvement in floriculture, I have bestowed a good deal of attention on the different modes of heating structures for horticultural purposes; in fact, I have the three different methods commonly used at work on my own premises. The old brick flue system was good till superseded by the hot-water system; and that was reckoned the *ne plus ultra* till the application of heated air was introduced; then came the war of words, Air *versus* Water. The late Mr. Meek, though not the inventor of the system, was the first who applied science and brought it to perfection. I had the honor and pleasure of his acquaintance, and he was the only man I have met who thoroughly understood the whole system. When Mr. Meek first introduced his system, I made a point of visiting every establishment round London that erected a Polmaise stove, and I never found one that thoroughly carried out the laws of science; one erected one thing, and another had another plan, and called it Polmaise, and every one was a total failure; hence the whole system got completely condemned; but, having erected my own upon purely scientific principles, I have now had six years trial of mine, and I find it answer better than either the flue or hot-water; and my gardener, who has had considerable experience, prefers it to either. Your correspondent, Mr. Craddock, gives a very excellent account of the working of the system, when done in conformity to the laws of science. Mr. C. is in error when he attributes the discovery to the late Mr. Meek; he brought it from the wet blanket of the discoverer to what it now is—the most perfect and natural system that can be invented.

My only object in addressing you is to create or renew a temperate discussion of the merits of the hot-air stove to the other methods of heating. During the heat of the last discussion the hot-water gentlemen were anything but cool upon the subject. F. H. S.

BEE-KEEPING FOR COTTAGERS.

(Continued from page 447.)

MAY.—Breeding for the next three months will proceed rapidly; continue, therefore, to supply water, if the weather be dry. The bees will by this time be fully at work.

b. Hives four years old and upwards should be allowed to swarm; keep the centre holes in these hives covered up. In hives less than four years old it is desirable to prevent swarming; keep such hives shaded from the sun, and give the bees in them more room by putting on small bives and boxes: a piece of perforated zinc laid over the hole in the centre of the hive (or of the super if there be one upon it), by allowing a current of air to pass through the hive, assists in keeping it cool: the zinc must be removed and cleaned as the bees stop up the holes in it.

m. Drones begin to appear, and, where swarming is about to take place, young queens are rapidly coming forward.

n. It is not always possible to prevent swarming, neither is it possible to ascertain with certainty when first swarms will rise: the hives must, therefore, be watched from ten o'clock till four from the middle of this month to the end of June. Swarms should be hived as soon as they settle, and should be set up on the pedestal next to its parent hive as

soon as hived; if allowed to continue where they alight, even till night, many bees will return thither the next day and will be lost.

Second swarms will most likely come off between the ninth and fourteenth days from the rising of the first swarms; the means of ascertaining the exact time is indicated in Section 1, under the head, "third swarms:" if second swarms rise before the end of this month, or even the beginning of next, and are large, they may be set up; if not, they, as also third swarms (which do not very often come off), should be either returned to the parent hive or joined to some other second swarm that *has* been set up, or to some weak stock: second swarms, if set up, may be placed on a pedestal to be fixed next to the parent hive in the space directed in the second Section to be left between each set of two pedestals. Should the weather be bad directly after swarming feed a little, otherwise the bees will most likely perish. Any sweet syrup given in a saucer, with some bits of wood floating in it, will do for feeding with at this season. Do not fix down the hives with clay or mortar; the bees will do this themselves, far better than it can be done for them, with the propolis or gummy substance which they collect from the horse chestnut and other trees.

JUNE.—All the directions for last month apply to this, except as regard setting up second swarms: the directions already given relating to these must be attended to: the bees in them will do more good to the bee-keeper now, if joined to other hives, than if set up in separate stocks.

Keep all plants round about the entrances below the level of the floor-boards.

e. In good seasons, small hives and boxes will be nearly if not quite full; if full they should be taken away. When, however, the supers are about three-quarters full, more room should be given, or a swarm may rise from the stock. A super is full when all the cells are ceiled over: where there are small glass windows in the supers it can be easily seen whether they are full or not: where there are not windows, discretion must be exercised: as a rule, when the bees begin to cluster at the mouth of the hives, the extra room should be given, and about a fortnight after this (if the weather has in the mean time been fine), the full supers may pretty safely be removed.

(To be continued.)

TO CORRESPONDENTS.

IRIS PAVONIA (*A. B.*).—We are much obliged for the additional reference, to which we have access, but not just now. We shall consult all such authorities very shortly, and give the fruit of our harvest; meantime, we may remark, that no British author, nor gone to his rest, is worth consulting on the practical question of bulb culture, except Sweet and Herbert; and that what Andrews said of this Iris, long, long ago, might be said of *Disa grandiflora* down to 1850; and yet both are as easy to keep and to flower as any other Cape bulb.

DAHLIAS (*Poor Richard*).—If you have the needful, and the courage to go to work in earnest, you may excel all the florists of the age with Dahlias, without an inch of glass, talk, or canvass, or with no more heat and light than reach you through these pages. "Do" them exactly as they do potatoes—plant out all your roots forthwith, and cover them one inch. In a few weeks the roots will have sprouted, and you can then increase them by "sets," like potatoes, keeping one or more eyes to each set; and every set is the fit for planting anywhere.

ARCHED CLIMBERS (*Inquisitor*).—It is too late now to get in these climbers, unless you had them all on the spot, and the ground ready for them. The best kinds of deciduous ones are, *Clematis montana*, *C. flammula*, *C. Hendersonii*, and *Aristolochia siphon* for the large leaves. The common trumpet, and Japan Honeysuckles; Virginian creeper; and a choice from running Roses, with a few of the strongest hybrid China Roses, or say *Ringa*, to represent the Ayrshires. Of creosote Boursaults, as the best of that section, *Laura Dawnant*; of the Musk cluster, *Felicite Perpetuel*, *Garland*, *Bluirii*, *Fulgens*, *Chexedole*, *Charles Duval*, *Great Western*, *Paul Ferras*, and *Coup d'Hebe*. But you might try *Wistaria sinensis*, Passion flower; *Clath of Gold*, and *Sulfatere* Roses, and such like, if you are in the south of Ireland or of England.

PEAR BORDER (*Ibid.*).—For pyramids, as you propose, from six to eight feet wide will be necessary; but three feet would be enough to begin with.

INDIAN SEEDS (*C. M.*).—We can make out every one of them, and they are the best selection we have seen for many a day. These long lists—which are of no use or interest to any one but the possessor—we would advise to be sent, for the future, with a stamped envelope, and with the address of the party, leaving us space of clean paper to give our opinion. A cold frame will do to get up the following, if sown at the end of April—1, 6, 7, 8, 9, 12, 14, 15, 22, 24, 29, 30, 31, and 39; and 6, 7,

8, 9 (conifers), should be in friable loam, and have little water. Try 11, the Gigantic Lily, in a cold frame also; no one succeeded with it in heat. A warm frame, or gentle hotbed, will be necessary for 2, 3, 4, 5, 10, 13, 16, 17, 18, 19, 20, 21, 23, 27, 28. Send 26 to the Crystal Palace, as one of the best Indiaa climbers (a *Bauhinia*). Give 32, 33, and 34, to the poultry—such melons and water squashes are of no use here. 35 is probably a kind we sent there in 1845, the best Suffolk cucumber. 40 is *Phaseolus* something, but of not the slightest use here, though it would be useful at Natal or Melbourne. We would try one-half of 30 (Balsams of all colours) in the open air, also 36 and 37.

BRAVOA GEMMINIFLORA.—Mr. Beaton says,—"When I saw your picture of this pretty bulb, at page 373, I thought your engraver was not much of a botanist, for he altered one of the chief points of its specific character by lengthening the style, or female organ, too much beyond the tube; and, as you said that I wrote something on this plant in my series on half-hardy bulbs, I felt that I was booked with your artist, as birds of a feather. So, to right myself, I looked into 'The Botanical Magazine,' whence you took your figure; and now I can tell you, that I never wrote a word about the plant in the Magazine at all. The plant which is figured from the collection at Kew is quite a different thing from the one called *Bravoa gemminiflora* in my series; but it may be the true *gemminiflora* for all that, and mine another species. I have no access to the original descriptions in the foreign works to refer to. My authority stands thus:—In 1837 or 1838 I had my *Bravoa* roots direct from Mexico. They were gathered by Galeotti, and Dr. Herbert was with me when I unpacked them. He was puzzled with these roots; but he could tell all the rest of the bulbs in the dry state. I flowered several of the roots out-of-doors, in a narrow border in front of a hothouse, and I immediately recognised them from the coloured figure of the species in the "*Amaryllidæ*." Dr. Herbert saw these in flower with me several times, and said they were *gemminiflora*. The one represented in 'The Botanical Magazine,' if it is not flattered, is a much brighter flower than mine, and no two species need be more different in the style of growth. The one at Kew is shown with short, stiff, upright leaves; but my bulbs or tubers were long-leaved after the manner of *Trin viridiflora*, but not so stiff, and they bent over like the tail-feather of a Spanish cock. Mine flowered from the latter part of June to the end of August, but did not ripen seeds."

CUCUMBERS AND MELON PITS (*F. E. R.*).—Yours are heated by flues, in chambers, and with a pan of galvanised iron above, for retaining moisture. We do not think there is anything decidedly new in the idea, but it is a good one, and we must have a little time to ponder over it, and make a few remarks, and perhaps accompany them with the section you have sent.

TOBACCO SEED (*W. Z.*).—You wish for the quantity for a piece of ground 6 yards by 4. We presume that you could get it from the nearest nurseryman, and, at any rate, from any Metropolitan seedsman. A very small packet would be sufficient, such as a quarter of an ounce. In fact, a single pod would yield far more than you would want. A few pence would be the price. A few years ago we had enough for a farm, but have got out of it. Ask for the Virginian large Tobacco. The cucumber frame would be the best for raising the plants, pricking them out in pans there, and hardening off in the greenhouse before planting. If you have no frame use the greenhouse, but keep the seeds covered with a glass; put a piece of paper over it at night to keep in the heat; and when the seedlings are pricked out, give them what excitement you can from a high temperature and a moist atmosphere. Much may be done this way with a little contrivance. The stronger and healthier your plants by the end of May, the heavier will be the yield of leaves.

PENSTEMON SEED (*D. E.*).—Sow this in any light, sandy soil; prepare the pots as you would see advised for seed pans generally, when treating lately on Pelargonium seed; cover with about the thickness of the sixteenth part of an inch, or a little less; and if you can place the seed-pot in a nice bottom-heat, and the soil be moist and not wet, the plants will be ready to handle in a few weeks—sooner or later, according to the age of the seed and its goodness; and then dibbed out into an intermediate bed, or into other pots, and planted out-of-doors towards the end of May. The plants will bloom early in autumn. If you cannot give the seed these advantages the plants will blow late, or not at all this season, reserving their beauties until another year.

VERBENA SEED (*Ibid.*).—Treat this in the same way, only add a little leaf-mould and peat, if you have got it, to the sandy loam, and a little white silver sand. They will want hardening off rather more early than the *Penstemon*, or the green-fly will trouble them. It is generally best to plant them out in rows, in order to prove the kinds. The seed is often self-sown; and the plants are often very vigorous from such seeds left in the ground all the winter.

WHITE FUCHSIAS TINGED WITH COLOUR (*J. M.*).—We fear we cannot assist you. Are the flowers which you mention (*Acantha*, *Diadem of Flora*, *Male's Bride*, *One-in-the-Ring*, *Pearl of England*, *Purity*, &c.) much more coloured than your neighbours? Of course, you merely mean the white calyx, for all these have the corolla more or less coloured. Even the calyx is but seldom a very pure white. There are two white ones we would recommend—*Prince Arthur* and *Duchess of Lancaster*; but we question if even the white of these would be pure enough to satisfy you. You shade quite enough to keep your plants in high health. If you gave more shade and less air, we believe that the colour would be paler; but we should not like to say much for the health and vigour of your plants. We are more inclined to think that the colour, if more perceptible than general, may be owing to the gross feeding, or too much manure-water.

GREENNESS ON THE OUTSIDE OF POTS (*Ibid.*).—Washing with warm water holding soda in solution will prevent the greenness to a certain extent; but too much soda imbibed by the pot would hurt some plants. The best plan is to wash them clean, and then make sandstone pots of them, by painting them outside, and throwing on as much silver sand as the paint would take up. The most stylish remedy would be to set your common pots out of sight, inside of little vases, of any shape or form, that would suit pots, and of such a material as would not allow cryptogamic plants to enrust its sides.

DIPLODENDIA CRASSINODA (Mould).—We have a perfect recollection of receiving your MS., but cannot find it anywhere. Please to let us have another copy. Why not let us have your direction? for we often wish to communicate with our correspondents. We should write to you now if we knew how to address you.

BIRMINGHAM POULTRY SHOW (E. Lister).—We sympathise with you most heartily, for we, at other shows, have suffered from similar mistakes. At the same time, we know that the committee last year used every effort to avoid such errors, and to get off the fowls to their owners without delay. We also know, from personal experience, the difficulties attending such efforts, and when losses, notwithstanding, have occurred, we have always replied to claimants for compensation,—"No one regrets more than we do the loss you have sustained, but we did our best to avoid it, and you must remember the exhibition was for your advantage; we derive not a fraction of benefit." If the Committees of Poultry Exhibitions were to be held responsible for all losses we do not know who would be induced to accept office.

GARDEN MICE (Goddess).—We have always found coal-ashes sifted very fine and put an inch thick, and four inches wide, over the rows of Peas and Beans, an effectual barrier against these marauders. We think the application would be equally conservative of Crocuses.

VINE-SHOOTS BLEEDING (Amateur).—As they are small, try what twisting a piece of strong wire round the end will do, continuing the twisting until the sides of the sap-vessels are crushed together. As the bleeding is "not very great," you need not be fearful of injury to the Vine's fruitfulness. You need not be surprised that Collodion, Roman Cement, and Resin, all failed to stop the bleeding; for the force with which the sap of the Vine rises has been proved to be equal to supporting a column of water thirty-six feet high, "which force is nearly five times greater than the force of the blood in the great crural artery of a horse."—*Hale's Statistics*, 1, 114.

CAPT. SNELL'S SHANGHAES.—"I have been informed an impression is abroad that I was an unsuccessful exhibitor at the late Metropolitan Poultry Show, and that my Buff Shanghaes were there beaten. Allow me to correct this error through the columns of your paper. My birds were not sent to the show in question, save one pen, forwarded for sale, AFTER the Judges had made their awards. Instead of sending to the London Show (it lasted much too long), I sent my birds to Torquay, where they took the first prize, as they had (except second prizes on two occasions) previously done at every show in England at which they had been exhibited.—W. H. SNELL, *St. Swithun's Lane, London.*"

MELON AND CUCUMBER BEDS (A Constant Reader).—Saw-dust at the back and front of the Melon-frame will do no harm to the plants, neither will watering stable dung with manure-water previously to building a hotbed with it; but clear water would do as well for moistening the dung, and the manure-water would benefit your Cabbages and Roses.

BLACK MALAYS (M. F. G.).—Your description seems to apply to the relative sexes of the Black variety of the Malay Fowl; the properties of which birds are in every respect identical with that of the species. The powers of flight, however, indicated by the readiness with which they surmount a nine-foot fence, are certainly in excess of what is usually seen in these birds. But without personal inspection we could not take upon ourselves to pronounce, in this instance, on the probability or otherwise of the existence of any cross with other breeds.—W.

SHELL-LESS AND IMPERFECT EGGS (C. J. S.).—No wonder that your Shanghaes lay such eggs; but it is a wonder that half of the hens have not died of paralysis. We never heard of such a poultry diet before: "Being the proprietor of a boarding school, you have so many broken pieces that your fowls have scarcely any other food, such as rice, broken pieces of meat, &c.,—perhaps more bread than anything else." Do not give the hens any physic, but discontinue all *meat*, and let them have nothing but the potatoes, rice, and bits of bread, mixed with an equal quantity of fine pollard. The best and cheapest work on Gardening is *The Cottage Gardener's Dictionary*.

SPANISH FOWL (T. F.).—You must not keep more than four hens and a cock in your very confined space. Your mode of dividing it will be useful.

WHITE DORKING HEN (Moira).—It is impossible to advise you upon such scanty information. Your other communication will be noticed fully next week.

SPANISH HEN (W. Curtis).—A slight stain of blood upon the egg need cause no alarm. To prevent an increase, however, give her, at an interval of two days, two pills, each containing one grain of calomel and one-twelfth of a grain of tartar emetic. Keep her upon soft food also for a week.

CAMELIAS FROM CUTTINGS (T. P.).—The double Camellias will not bloom well upon their own roots. They are grafted on stocks of the single Camellia. These stocks are raised from cuttings of the nearly ripe new shoots, near the end of June. They readily strike in well-drained pots filled with sandy loam plunged in a cold frame.

TRAVELLED EGGS (A Regular Subscriber).—Eggs may be sent hundreds of miles and produce chickens afterwards. We know of thirteen eggs which, after journeying 300 miles (from Winchester to Keadal), produced last month nine chickens. They were in a strong box, two inches of bran at the bottom, then an inch layer of oats, on this the eggs were laid on their sides, covered an inch deep with oats, and then two inches deep of bran.

INDUCING ROOKS TO BUILD.—A *Subscriber* would be glad to know if there is any mode of inducing Rooks to build and settle in old trees. Putting old rooks' nests in them has been vainly tried; the rooks came to them, but only to steal the sticks of which they were formed.

BAHMA POOTRAS (Linda).—They are nothing more, at the best, than Grey Shanghaes. Their eggs are not better, nor do they lay any more than other varieties of the Shanghaes (Cochin-China). The Buffs are certainly as good as any. The early pullets will begin laying in October, and continue to do so throughout the winter.

SHANGHAES RUNNING WITH BANTAMS. (Sebright).—Physical inability, from the extreme disproportion of size, is your only safeguard.

TIME FOR SITTING (Amicus Gull).—We consider March, April, and early May, the best periods for sitting all kinds of poultry. The chickens then have the warmest period of the year to grow in. Your other questions will be answered next week.

NAMES OF PLANTS (Sophia).—No. 1 is *Pteris serrulata*, or Various-leaved Brake. No. 2, *Lycopodium helveticum*, or Swiss Club Moss.

LONDON: Printed by HARRY WOODBRIDGE, Winchester High-street, in the Parish of Saint Mary Kalender; and Published by WILLIAM SOMERVILLE ORR, of Church Hill, Walthamstow, in the County of Essex, at the Office, No. 2, Amen Corner, in the Parish of Christ Church, City of London.—March 23rd, 1854.

Advertisements.

MR. WILKINS, residing at Bedford Cottage, Walmey, Kent, within a short walk of the beach, receives a few little boys from seven to twelve years of age, to prepare for the public schools. Terms, Seventy to One Hundred Guineas.

Reference permitted to The Rev. Lord Wriothlesley Russell, Chiches, Rickmansworth, and The Hon. and Rev. Douglas Gordon, the Rectory, Stanmore, Middlesex.

HORTICULTURAL BUILDING and HEATING BY HOT WATER.

EDWARD and A. WEEKS, Park Cottage, King's Road, Chelsea, are now in a position to execute any of the above work in the very best manner, and at a reduced price. Materials and workmanship warranted of the best quality. Plans and estimates forwarded on application for the Building and Heating of all kinds of Horticultural Buildings; as also for the warming of Halls, Churches, Mansions, Public Buildings, Offices, &c.

EDWARD and A. WEEKS, PARK COTTAGE, CHELSEA.

SHRUBS, FRUIT, & FOREST TREES, SEEDS,

&c.—Sycamore, Chestnut, and Walnut Trees, five feet high, 3d each; Laurels, 2d each; Privet, 1d each, four feet high; Red, White, and Black Currants, three feet high, 4d each; Hex Oak, English Yew, Cypress, variegated Holly, Gold and Silver leaf Fuonyuus, Arborvitae, Honeysuckles, Clematis, Virginian Creepers, Laburnum, Lilacs, Moss, and Running Roses, Berberis, Double-blossomed Furze, Cotoneaster, in pots at 6d each; Escallonia macrantha, 1s each; Standard Roses, 1s each; Cedrus deodara, 1s to 2s each; Acuba japonica, 1s each; Flowering Almond, 2s 6d each; Tulip Trees, 2s each; Cryptomeria japonica, 3s each; Box-edging, 4d per yard. Every other shrub, flower, or tree, at equally low prices. At W. CULLINGFORD'S, 1, Edmund Terrace, Ball's-pond-road, Islington, London.

FLOWER AND VEGETABLE SEEDS OF EVERY KIND.

BEAUTIFUL FLOWERS.—50 Varieties of Flower

Seeds, 6d per ounce. 30 varieties of beautiful sorts, 1s per ounce. 50 varieties in half-quarter ounce packets, 4s per ounce. 30 varieties in packets, 3s per ounce.

Any kind, in 1d and 2d packets sent free by post upon receipt of a stamped directed envelope. Vegetable Seeds of all kinds, Shrubs, Flowers, &c., at Mr. CULLINGFORD'S, 1, Edmund Terrace, Ball's-pond-road, Islington, London.

GIDNEY'S PRUSSIAN HOE.—No Lady or Gentle-

man having a garden ought to be without one of these useful garden tools. Price 1s 6d, handled. To be had of all Ironmongers and Seedsmen.

Manufactured only by GIDNEY & SON, East Dereham, Norfolk.

BUDDING'S LAWN-MOWING MACHINES,

WITH REGISTERED IMPROVEMENTS.

MAPPLEBECK & LOWE, MACHINISTS & MANUFACTURERS, BIRMINGHAM.

TANNED GARDEN NETTING, for protecting

fruit-trees from frost, blight, and birds, or as a fence for fowls, pigeons, tulips, and seed-beds, can be had in any quantity, from JOHN KING FARLOW'S Fishing Tackle and Net Manufactory, 4 and 5, Crooked-lane, London-bridge, at 1d per yard one yard, 3d two yards, or 6d four yards wide. Carriage free on all orders over 20s, accompanied by post-office order or London reference. Rabbit, sheep, and fishing nets, of every description, in stock, or made to order.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last twenty-seven years, the average highest and lowest temperatures of these days are 55.2° and 35.6° respectively. The greatest heat, 78°, occurred on the 3rd in 1848; and the lowest cold, 21°, on the 5th in 1845. During the period 113 days were fine, and on 76 rain fell.

NEW PLANTS.

GOLDFUSSIA GLOMERATA var. SPECIOSA (*Clustered Goldfussia, variety Showy flowered*).

This was originally introduced as *Ruellia glomerata*, and came from the Botanic Garden at the Island of Mauritius. The species, however, is now added to *Goldfussia*, and the above is a variety of it with bright purple flowers, rendering the plant more showy, as it is also by the numerous reddish hairs upon its bright green leaves. It is a stove plant, about eighteen inches high, and flowers in November. It belongs to the Natural Order of *Acanthaceae*, and to *Didymania Angiospermiæ* of Linnaeus.—(*Botanical Magazine*, t. 4767.)

EPIDENDUM STAMFORDIANUM (*Mr. Stamford's Epidendrum*).

The flowers of this Orchid are in racemes, greenish-yellow, spotted with red, and fragrant. It blooms in our stoves from February to May. It was found at Guatemala, by Mr. Skinner, and at Santa Marta, by Mr. Purdiè.—(*Botanical Magazine*, t. 4759.)

DICHORISANDRA PICTA (*Painted-leaved Dichorisandra*).

This belongs to the Natural Order of *Spiderworts*, and to the *Hexandria Monogynia* of Linnaeus. It has been known ever since the year 1830, but is now for the first time, we believe, depicted. It is a native of Brazil, and has been for some years cultivated in the Kew stoves. "The spotted glossy foliage, and the purple and white somewhat fragrant flowers," render it attractive. The plant is rather more than a foot high.—(*Botanical Magazine*, t. 4760.)

ANGRECEUM EBURNEUM (*Ivory Angreecum*).

This Orchid is about two feet high, and is thus mentioned by Sir W. Hooker. "It is not possible to render justice to this noble plant on a quarto page. All we can do is to give a reduced figure of the entire plant, and a portion of a leaf and of the spike of flowers of the natural size, as they appeared on our specimens at Kew, which we derived from the collection of the late Mr. Clowes. The species is a native of Madagascar and Bourbon, and is yet very rare, we believe, in our stoves. The first plant was imported by the Horticultural Society from the former island, through their collector, Mr. Forbes. The flowers, unfortunately, have neither colour nor fragrance."—(*Botanical Magazine*, t. 4761.)

ALLOSORUS FLEXUOSUS (*Zig-zag Allosorus*).

This Fern is to be found mentioned in various botanical works under the different names of *Pteris*, *Pellaea*, and *Platyloma flexuosa*, and *Pteris cordata*. Under the last name it has been known as long since as 1820. It reaches to the height of four or five feet, and requires support, being a climber, by the aid of the angles of its branchlets. It flourishes in a temperate Fern-house. It is a native of Peru and Mexico.—(*Botanical Magazine*, t. 4762.)

PROTECTING materials have been often noticed in these pages, and yet the gardening world is pretty well divided as to the policy and impolicy of using screens for fruit-trees. No one who rightly examines the subject can fail, in some measure, to join with Mr. Errington, as to the propriety of *retarding* the blossom of fruit-trees until the ground temperature permits of a reciprocal action between roots and branches. Taking this for granted, the importance of being able to use one and the same material for retarding blossom, and then protecting it from cold when opened, becomes at once apparent. The chief difficulty has been to find a material economical in its cost, easy in its management, not likely to get out of order, and which, during the

bustle of the spring months, would not monopolise too much time for attendance.

Nothing could answer better for retarding than thick canvass cloth, let up and down by pulleys. Few things equally economical would prove such a protection against sudden and severe frosts, because, in addition to other properties, the blossom would be kept comparatively dry, and, therefore, not exposed to the sudden chills of a rapid evaporation before the frost wrapt them in his folds. But if you allow such a covering to remain on during coldish, dull days, and either cold or warm nights, then your buds, when you wish to retard them, will become weak and drawn; the very opposite of robust and sturdy. On the other hand, when using the

covering at night, when the plants are in bloom, equal judgment is required during the day; if at all mild, though dull, it should be wholly drawn up; if moderately sunny, the same; but if a very bright sun comes with a keen, searching air, the difficulty is whether to remove it or not, the thick shade weakening the blooms, and preventing the due dispersion of the fertilising farina of the stamens; while an unshaded sun, especially after a few shaded days, parches the buds and young shoots, and though the effect is not quite so perceptible, exercises a similar influence to what the sun's rays do on a cutting or a plant just beginning to push its roots.

These, and similar considerations, and the time involved, have led many of our best gardeners out of the dangers of extra covering and no covering, to choose the least troublesome, and though not always the case, yet many instances are known in which the seemingly careless, trusting-in-chance men, were rewarded with better crops than their neighbours, who had attended to the whole routine of covering, not forgetting even the minutiae. It is no wonder, therefore, that all who can be raising up Orchard-houses, in which plants have air, heat, light, and shade, easily regulated according to their circumstances. Every one who has had to do with early fruit of the stone kind knows,—such as in the case of a Cherry-house,—that a slight shade in a hot sunny day, when the trees are in bloom, is one security for obtaining a good setting, and the same of Peaches; but, though very thin netting or bunting would be valuable for this purpose, a thick canvass applied for any length of time would make the remedy as bad as the evil.

When employing strong sheeting for fruit-walls, we have often wished, in such circumstances, for a thinner blind, not to obscure, but merely to blunt the force of, the sun's rays; but where can we expect to get the come-at-ables for double covering, to be used in this manner as circumstances require? Or who is there, that with an eye to economy, not as respects one season, but for a period of a dozen or twenty years, would not enquire whether the money and the time spent upon covering might not get up a good Orchard-house at once?

It will at once be seen that the objections thus made to a thick, moveable covering apply with greater force to an opaque fixed protection of any kind, as the trees are apt to be kept too warm at one time, when we should like them to be cool, and too dark at another, when we should wish them to have light. Nevertheless, after many trials and experiments, we are of opinion that any modes, however simple, of retarding and protecting, are better than none; and that all things considered, when time and attention are given, and proper simple machinery for quickly elevating and lowering used, a stout canvass is the best, though it will prove a little expensive; as we are not aware that any article has yet been manufactured peculiarly for the purpose. We have witnessed several instances of fine crops, where these screens were carefully used, and next to a complete failure when they were discontinued; but, as we

mentioned at first, we have, also, seen failures with their use, and great success, a short distance off, where no protection at all was given.

Granting, then, that protection and retardation, combined, are advantages, the possibility of uniting the two, in any degree, by a *fixed* medium, which will alike keep out heat and cold, though in a limited degree allowing as much light and air as will prevent weakening the blossom, and not so much as to parch them in early spring, and, withal, extremely cheap, must be desirable for amateurs, who cannot give the attendance that a strong canvass would require, and also for gardeners, who either cannot give that attention, or who have some doubts of the propriety of using it. Such a material we have now had in use for several years. It is *Nottingham Thread Net*, rather fine but tough; the hexagon openings being about the eighth-of-an-inch, of course smaller one way, when there is a strain upon it. A new piece attracted one of our best gardeners the other day, and he pronounced it to be, all things considered, a most desirable article, as saving all bother, admitting enough of light, and keeping out a certain amount of cold. It was procured, by post-office order, from Messrs. Boden and Co., of Nottingham. They state that such coarse nets are made in pieces 158 inches and 198 inches wide. One of these narrowest pieces, with a supply of tape or list, top and bottom and ends, to fasten by covers, comfortably, a wall about twelve feet in height, for fully forty-five yards in length, and the appearance is very neat.

Of course, this would neither retard nor protect like canvass, but it will do a little in the way of both, and, therefore, be not without its use. One thing against it is, that it will not keep out rain, but the drops are broken and dispersed considerably before reaching the wall, especially if there is a wide coping, and the covering is two or three feet from the wall at bottom. On the morning of the 20th of March, we had from four to five degrees of frost, but it did not reach the wall, and from rain having fallen freely the day before, the ground was frozen hard outside the shade of the covering,—it had not gone beyond an inch inside, the ground there being quite soft. A few Peas had been planted out two days before, protection being given with boughs,—some against the wall, some on the border; those on the border, though not injured, were stiff and flat upon the ground in the morning; those at the side of the wall were soft and erect. Be it also remembered, that on the day after their being planted out, we had only a few gleams of sunshine, and, therefore, that the temperature maintained was not greatly owing to the heat of the wall.

Such netting is not only valuable thus for protecting blossom, but also for protecting, and saving, and retarding fruit, and for shading purposes. It will require a very fine-winged insect to find its way through it. Gooseberries of the *Harrington* kind were had the best part of two months last year, after they were gone in the open garden, from using this netting. The plants were on a north border; the netting was fastened by

one side to the wall; and as it was not long enough to reach the ground, a slight rail was put up to fasten it to on the other side, and then, from thence to the ground, mats and netting were fixed lengthwise.—R.

In a former paper we suggested some analogies between the facts connected with the propagation and dissemination of cholera, and those laws under which certain minute organised growths, as funguses, blights, and the like, are admitted to exist and spread. We have ventured to refer, also, to the old Jewish ordinances respecting the leprosy, which, according to the authorities cited by us, were not opposed to our present impressions on the subject of contagion generally.

The following is a summary of the whole of our present knowledge upon this subject, carefully collated from the report of Baly and Gull, to which we have already referred. We are not without hopes that our readers will now, at least, be able to form for themselves a sufficiently accurate notion of the matter to guide them in all things which pertain to their own conduct; and, indeed, much more accurate than many impressions upon which they are continually obliged to act in their daily concerns.

The foregoing enquiry has been directed to the discovery of the relation borne by the atmosphere to the spread of cholera. The results arrived at lend much support to that theory of the cause of Cholera which regards it as a morbid matter or poison reproduced in the air, and diffused in part, at least, by atmospheric currents. Such a poison brought by the atmosphere to this country might soon be dispersed over many parts of it, and would meet with a suitable nidus for its reproduction in the lower districts near the mouths of rivers, while in parts where the atmosphere from its dryness and purity failed to afford the necessary conditions for its increase or maintenance it would perish.

The unequal distribution of the disease in the winter of 1848-9, would, therefore, be quite intelligible. Its absence, in some parts, where the conditions of unhealthiness abounded in towns and other inhabited places, would be accounted for; since the supposed poison, if it did not perish before it reached these inland or more elevated districts, would find then a [general] atmosphere unfit to preserve its active properties, and to communicate it to the [particular] spots in which it could increase and produce its effect on the inhabitants. The comparative intensity over other parts, for short periods, in the same season, would also be intelligible; likewise, the lingering of the disease in the spring of 1849 in certain spots distinguished for the most part by the local conditions productive of a damp and impure air.

The renewed rise of the epidemic in the summer might be reasonably referred to the increase of impurity and moisture in the air under the influence of a rising temperature, and, perhaps, other meteorological conditions; to the consequent increase of the poison in localities where it already existed; to its distribution by

the air from these foci to other places more or less distant; to its increase in these again, if they afforded the necessary conditions; and its further diffusion. Thus the extent of the disease over the country, and its intensity in each large town, would continue to increase together, and the climax would be reached everywhere nearly at the same time. Lastly, when with the fall of temperature the atmosphere had begun to lose the properties favourable to the transmission of the poison, comparatively few fresh places would become affected, and the epidemic would gradually subside.

At the beginning of summer the poison would find the means for its dissemination, and increase soonest where the sources of damp and impurity most abound. Towns in such parts would soonest become foci (whence it would spread to towns in the more elevated and more inland regions), and in the autumn and beginning of winter would likewise continue longest, to afford an atmosphere fitted to transmit the poison from spot to spot, and, inasmuch as the epidemic is maintained in each town by successive outbreaks in different localities, it would be expected to survive to the latest period where the conditions for the transference of the poison from one place to another existed longest. The exceptions to the order of attack, both of tracts of country and of towns, are equally in accordance with the theory; the purer atmosphere of elevated tracts of country rendering it difficult for the poison to reach the damp and foul localities in which it might increase and produce effects on the inhabitants. The late appearance of the epidemic in some coast districts scarcely offers greater difficulty; the state of the atmosphere varying in different parts of the coast at the same time, and in the same part at different times; the morbid matter, while spreading rapidly over one such district, might be excluded by the state of the atmosphere from another not far distant one.

The character of having the properties not of a gaseous substance, but of a matter in the form of solid or liquid particles, has already been assigned to the cholera poison. Such a poison being distributed only partially through the air, and carried hither and thither by atmospheric currents, might for a long time fail to reach a spot which was itself even well fitted to afford it the means of increase.

The climax of the epidemic was more nearly simultaneous in the different localities at the season and in the area most remarkable for impurity of atmosphere. For in an atmosphere uniformly or very generally impure the poison would find, in all parts of a given area, an equal medium of transmission from spot to spot, and, consequently, would increase everywhere equally, and reach the climax in all at or about the same time; as in the case of the registration districts of London (see pages 93, 94 of Report). But in the air not generally so impure, the transmission of the poison would be dependent on and more interfered with by accidental circumstances. Lastly, the fact, that around the more considerable foci slighter outbreaks occurred in places which from natural site or sanitary conditions had no

special fitness inviting the attack, is consonant with the idea of a morbid poison, which, while it increases in certain foci, is capable of being scattered around them by means of atmospheric currents. (*Dr. Baly's Report, pages 99 to 102.*)

Conclusions—I. The theory that the cause of the disease is a general state of the atmosphere, or general atmospheric influence, or epidemic constitution, has been found untenable.

II. The persistence of the epidemic for a certain time, even in localities of small extent, and its very partial distribution in a country, a town, or even parts of towns, are two facts which at once suggest that the cause of the disease is a material substance only partially distributed. Many spots within a limited area have remained free from it which exactly resembled localities attacked, in respect of the supposed localizing conditions. However, cholera is so far connected with the characters of low site and defective sanitary conditions that it is never very rife except where they are present in a marked degree. The natural inference is, that the matter which is the cause of cholera increases and finds the conditions of its action under the influence of foul, damp air, with the aid of some degree of warmth. This being premised, other facts become intelligible, namely, the persistence of the disease in winter in the interior of large establishments where there is warmth, together with impurity of air produced by the accumulation of many human beings within a limited space; the preference manifested throughout for low, densely-populated districts about the mouths of rivers; for crowded and dirty ill-ventilated towns and places; and, likewise, its appearing generally first in places of the character described.

III. A large body of evidence renders it certain that human intercourse has, at least, a share in the propagation of the disease; and that under certain circumstances it is the most important if not the sole means of effecting its diffusion. Thus, the epidemic has progressively advanced along great lines of human traffic, at a rate varying according to the activity and means of human intercourse in different countries, but never surpassing the rate at which men travel. In India, it has travelled for hundreds of miles, and for months in the teeth of the monsoon, and among bodies of troops marching through countries till then healthy, and has continued to prevail in ships for many weeks after they have left infected parts, appearing first at the seaports of any island or continent which it is newly invading: in a large proportion of cases its first appearance having been preceded by the arrival of ships from infected ports, and of ships actually bringing persons already affected with cholera. In several instances, the first patients attacked had had communication more or less immediate with sick persons brought in the ships. The facts, however, by no means sanction the belief that cholera is always propagated in this way; on the contrary, it is certain that the extension of the disease over large towns, if not over larger areas, may take place independently of communication between the sick

and the healthy. Where human intercourse cannot have been the means of diffusing cholera, the agent most likely to have conveyed the poison is the wind.

IV. The propagation of the disease by human intercourse does not prove its contagious nature. If the poison of cholera increases in damp and impure air, and is likewise capable of attaching itself to the surfaces of bodies, to the walls of rooms, and to furniture, it will also be collected by the clothes of persons living in infected dwellings; and wherever it meets with the conditions favourable to its increase and action will produce fresh outbreaks. Some facts which constitute presumptive evidence in favour of the dependence of the epidemic on contagion, have been found susceptible of explanation in other ways, though the explanations offered have, in some instances, been necessarily of a conjectural nature. The evidence respecting the especial liability of nurses and others attending the sick, though conflicting, is, in some instances, of such a character as to preclude the absolute rejection of the view that the disease has a contagious property, even though it does not usually spread by contagion.

V. The question whether the cholera poison enters the body through the lungs, or through the alimentary canal, has not been conclusively solved; but no sufficient reasons have been found for adopting the theory that the poison is swallowed by the food or drink; and if the character of the water drunk is not altogether destitute of influence with reference to the diffusion of cholera, at least its powers and effects are very inconsiderable in comparison with those of other conditions. That theory, then, alone is supported by a large amount of evidence which regards the cause of cholera as a matter increasing by some process, whether chemical or organic, in impure and damp air, and assumes that although, of course diffused with the air, it is also distributed and diffused by means of human intercourse. This theory explains much that would otherwise seem capricious in the course of cholera, and elucidates the relations subsisting between cholera and other epidemics. The similarity of the local conditions favouring cholera and epidemic diseases generally, together with other facts, agree best with the view that these several diseases are caused by different poisons, all of which find their means of increase in similar states of atmosphere, though these, probably, are modifications of atmospheric conditions more essential to some of these diseases than to others. In the statement that the theory above indicated is the only one supported by a large amount of evidence, it is not implied that this theory is adopted to the exclusion of all others. (*Dr. Baly's Report, p. 214 to 221.*)

J. J.

A FEW WORDS ABOUT HAND-GLASSES.

For many years past a notion has existed with myself that a revolution, or rather a reconsideration, is necessary in the matter of garden-tools, glasses, and other appliances so necessary to good gardening. I am, indeed, astonished—seeing what a chance offered,

that no person, as far as I am aware, has ever gone into the question in earnest.

The whole gardening world knows that their attention was strongly invited to what the French call "*Cloches*," about a year or two since. As I do not like to be in the rear of any question of importance, I set to work anew as to the hand-glass subject, to see if (unfettered by the idea of what had been done) I could by any means suggest progress. I certainly have nothing *very new* to offer; but my examination of that subject has not been, I trust, without some use.

Knowing that the Messrs. Pilkington, of those enormous glass-works situate at St. Helen's, Lancashire, were of that class of dealers who earnestly desire progress, not only on account of profit, but an emulous desire to "go a head," I wrote to the firm, respectfully drawing their attention to this affair about the "*Cloches*." I must here confess, that not knowing any of them, I took the credit assigned to their establishment "on tick;" or, in other words, I was prepared to believe they were first-rate tradesmen; and I have never met with any reason to doubt it.

One of the principals, who signs himself "M. Pilkington," very kindly answered all my inquiries, and, moreover, forwarded me three or four specimen glasses, in order to see if any real advance worthy of the year 1853 could be made. I must now first state my objects in dipping thus into this question.

In common with many other gardeners, I had long lamented the great cost of our ordinary hand-glasses; for a few years since it was no uncommon thing to give twelve to fifteen shillings each for them, and in the rage after novelty they had, in many cases, so altered their original character, as to make them tedious to work, and, of course, exceedingly liable to breakage. It was obvious, too, that any mode by which their make and cost would be simplified and reduced would tend much to their extension; and, indeed, in the latter respect, I have no doubt that before many years have passed these things will be so cheapened and simplified, as that acres will be covered where only poles are now. And what will then be the necessary consequence? Why, that a host of delicate vegetables, now esteemed dainties, and many of which are hourly imported from other climes, will be within reach of thousands.

Now, the faults attributable to the old hand-glasses were not faults of cost alone: in many cases they were so constructed as to be by far too liable to breakage; were too heavy and clumsy; or did not present the proper facilities for giving air or ventilation. As to breakages, everybody knows what an expensive item the frequent mending of glasses used to be in the glazier's account. This was particularly the case with the old lead glasses, which were, in general, most expensive, as well as unwieldy things. As for breakage, as soon as they were half worn they became, in general, so crazy that they could be moved but with difficulty; and it was no uncommon thing for those who had the temerity to do so, to crack two or three panes in the transit. The weight of such glasses, too, was much against them. It was not a mere case of trouble in removal, but that very property had a tendency at every move to derange the panes, as also the very fabric of the glasses. But one most important consideration, and one which should ever bias, in some degree, the hand-glass question, is the mode of ventilation and air-giving. Now, ventilation and air-giving, although constantly confounded, are not precisely the same thing, and it is necessary here to distinguish carefully; although some of our friends may consider it mere "spectacle work." To ventilate, in the proper acceptance of the term,—as I hold it—is to *invite* and *encourage* a circulation; to give air is to let a superfluous heat to escape; although

the latter must, of course, end in promoting a circulation, or even a slight degree of motion.

Now, it is well known, that in the old-fashioned glasses these proceedings were mostly accomplished by "tilting" them up at the bottom by a brick, or otherwise; and that this was a rather tedious proceeding if it happened to fall to the lot of a dawdling fellow, and many a pane has been shaken out or cracked by such incomplete machinery, when a daily performance. In considering this hand-glass question, it is absolutely necessary to take into consideration the fact, that in the majority of cases, such is the character of the ordinary hob-nail or wooden-clog labourer in country gardens—persons who perform such duties—are apt to be neglectful; and it is really necessary, in all ordinary gardening, so to plan such things as to put it out of the power of awkward or neglectful workmen to do mischief. To return, then, to the brick tilting. I, for one, must protest against the daily practice, believing that much better plans can be devised. As to tilting the heat escape, the tilt-up at bottom is by no means an efficient plan; it is a most unphilosophical procedure, and in practice it has been frequently found that plants beneath a glass thus treated may be both burned and starved at the same time. Who has not seen an illustration of this in one of those March days, in which, with a bright and burning sunshine, we experience one of those cutting and drying "north-easters," which have been likened to a Har-mattan? Here the unfortunate gardener, if compelled to tilt his glass to prevent burning, is obliged to let in a foe of an equally formidable character; and if his occupants of the hand-glass have been previously petted with a fortnight's muggy weather, the chances are that they will speedily look like withered parchment.

I have hitherto considered this question almost as an ordinary hand-glass question; I do not, however, wish to confine it within such narrow limits; the principles at issue, more or less, concern almost every glazed implement or structure connected with horticulture.

About twenty years since, I obtained some twenty-two-inch hand-glasses, from Birmingham, from the firm of Clark and Co., who were then building a range of metallic houses here. These glasses were to be everything a gardener could desire—framework copper, to avoid rust and expansion, moveable roofs, &c. They certainly were not bad glasses, but, in order to give them the appearance of much finish, &c., the very ingenious inventor had made them octagonal, which, of course, carried much higher pretensions than the old, vulgar, square ones could pretend to; and, moreover, on every side of the octagon where the moveable lid rested, a point or pivot was fixed, with a corresponding hole in the roof-piece; and every evening it became a most ceremonious procedure, requiring, of course, a superior workman to nicely fit these roofs on the base-ment portion of the glass. However, they looked so fine that we tolerated this nicety in operation for three or four years, when I thought it expedient to file off these gimcracks. I found, too, that in departing from the plain rectangular or the circular form little could be gained, but much lost; and I got a country mechanic to make a plain square frame, metallic, the roof moveable, and having a flange on the exterior edge at its base;—this flange to prevent blowing-off in storms, &c. The flange, when the roof-piece is put on, overlaps the base of the glass, and, of course, keeps out all drip, &c. Scarcely any ordinary hand-glass can excel this thing; it is nearly all that is wanted. I am not assured that it would be amended if a cooler current could be admitted at a low level in the base by some aperture capable of graduation; this might be well for a few things, and, indeed, is almost the only principle deserving of farther consideration.

To discuss the whole question in a single paper, such

as this, is impossible; and I wish now to draw attention to the "Cloches" of our French neighbours, and to point to a step in advance,—one, at least, illustrative of the business in hand,—made by the Messrs. Pilkington, of the St. Helen's Glass Works, in Lancashire, at my suggestion. Mr. Pilkington, it would appear, holds a commercial garden of his own, being fond of carrying out gardening matters with a high hand, or connected with the glass question: his garden, however, I have never seen. Such being the case, it struck me that he was in a position to appreciate the wants of gardeners. I suggested to Mr. Pilkington such arguments as I have used on this occasion, and begged of him to try his hand at a circular "Cloche," or what, when I was young, was called a "bell-glass," in the neighbourhood of London, but to make it with a moveable lid, something like a Sea-kale blanching-pot. Mr. Pilkington kindly sent me a specimen, which is, most certainly, a good thing, and points in the most unmistakable way to the possibility of future progress. If these hints should meet that gentleman's eye, I hope this will induce him to renew the race; and if any one wishes to go a-head in this matter, I would strongly advise him to put himself in communication with this firm, for I am told that their works are pre-eminent, both in character and extent.

By the by, speaking of "Cloches," or bell-glasses, I was reared and spent the first sixteen years of my life in the oldest nursery in England, but one or two, and we had lumber rooms all hung with spider tapestry, in which might be seen scores of these bell-glasses, or cloches, of a green, thick glass, full of "bulls-eyes," &c. They were rarely used, being said to be quite out of date long before the year 1810. We lads used to handle them very unceremoniously, but it was seldom we could persuade them to break. Before concluding this glass question, which I have brought forward with the idea of putting other heads to work, I may observe, that the metallic hand-glasses (which I before observed were made very complete by a country workman) are square, and the lids moveable down to the perpendicular portion of the glass, where they overlap with a flange. In giving air, ventilating, &c., we simply take hold of the handle and turn them slightly round, by which means an aperture is instantly produced at each angle, and this, of course, capable of any amount of graduation. Here, then, the heat escapes at a sort of half-height level, which will be formed, I think, just about the proper point to promote a speedy interchange of warm and cold air, or, in other words, air-giving and ventilation combined.

Messrs. Pilkington's model Cloche is about fifteen inches diameter (but may be had of any size); it has an aperture, in a sort of neck at top, about three inches diameter, and a little bell-eap inverted is placed over the aperture. The Cloche is circular.

T ERRINGTON.

FLOWER-GARDENS.

IF "all the world is a stage," England must represent the right part for a flower-garden, whether the *plan* be right or not; and the last half of March, with the early part of April, the busiest time for that part of the stage, so there is no time now for beating about the bush, which, if it is not pruned now, is not worth the time it would take to prune it at this busy season; cuttings, old plants, scarce plants and new plants, with seeds and seedlings, spring bulbs and flowers, and the summer crops which follow them, and the mode of succession, are the present and most urgent questions, and into them let us all dive at once, without preliminaries.

Since I left off gardening, I have learned more about the great bulk of flower-gardens than most people would believe. In large places, the gardeners have left off growing many annuals, because they have hothouses, and all that, to keep plants over the winter, and they find it less trouble to plant a bed or border once for all, at bedding-out time, than to fight and strive with seeds and slugs through the whole season. Go to the seed shops, however, and there you will learn that more than half the people grow annuals, and a great number of perennial plants, from seeds every year; and that the rage for this economy is getting more and more into the fashion every year. The advertisements about all sorts of seeds tell the same tale. Now, after all that has been said and written about seeds for the last twenty years, there is no better plan yet than the old one for filling borders; and this is how I learned that part thirty years since. We went to the compost-yard and sifted four barrow loads of rich light mixture, a part from heaps of loam, leaf-mould, peat, rotten dung, and the old rubbish-heap; we sifted very fine; then one man went before—a kind of officer in high trot; he fixed on the places where seeds should be sown, and with a light spade he made a hole in every such place, and spread the soil from the hole among the plants already in the border with great care; the holes might be from six to nine inches wide, and not more than four to six inches deep, along the walk and the centre of the border, but the back row of holes were deeper. I followed him with the barrowful of sifted compost, and filled up every hole he made; and the master came behind us with a whole basketful of seed-packets, bags, and papers, and lots of little sticks to mark the places or patches where he sowed the different seeds. I had the worst part; for if I stepped on a flower, or made a mess on the border, I stood between two fires. Some seeds he sowed in a ring round the patch, and others he put in broadcast over the whole surface, then put a little stick in the middle, and with his finger made a circle outside the patch to mark how far the seeds went; heavy seed, as Lupins, Sun-flowers, Sweet Peas, and such like, he would bury nearly an inch deep, but the smaller seeds he put in very lightly indeed; and he had a sign put to some of these, which his foreman understood to mean that a flower-pot was to be turned over on that patch, or these patches so marked, and the pots were put on the next day.

The empty pot over a patch of seeds has a good deal of meaning in it; seeds of *Lobelia* or *Calceolarias* are perfectly safe under a pot; the rain will not splash them about, the sun will not burn, or dry up the surface and cause them to fail, or be long in coming; cold winds, ditto; and the heat of the sun against the pot keeps the air warm under it day and night; the damp from below cannot pass, and the place is therefore moist enough for seeds without watering. As soon as the seeds are up the pot is tilted on the side the sun shines to give air and light; it is let down again at night if it is cold, but as soon as the seedlings are beyond danger the pots are gathered up in a barrow, and taken away for the season. Now, although one would hardly recommend pots to be stuck here or there, in face of the windows, the plan is so sure and good, that it may be very useful to some who have no glass, or better means than the open air to raise some valued seeds. Anybody may get up seedlings after the middle of April of such delicate things as the small blue *Lobelia*, the *Portulacacae*, and the *Mesembryanthemum tricolor*, *Salpiglossis*, *Petunias*, *Calceolarias*, and even *Rhododendrons*, and other American plants, by the use of pots put over the patches just in the same way, and although they would be much later than if they were in a hotbed, they will be all the safer, and make more hardy plants, which would grow with less trouble.

ANTIRRHINUMS.

The 20th of April is the right time to sow *Antirrhinum* seeds in the open air, so as to have the seedlings coming into flower, to succeed annuals, which are sown at the same time, or a little earlier. Mr. Appleby has referred to me for the value of this flower for beds, and that is the way I brought it in; but I never missed it for years, although I used it only as one of the auxiliary plants. If you sow a bed of *Carnation Poppies*, or any fancy Poppy, or a bed of *Clarkia*, or mixed *Clarkia*, or of *Candytuft*, or *Navdwort*, or *Leptosiphon*, or, indeed, of any annual of the month or six weeks flowerers, between the first and middle of April, and sow the *Antirrhinum* as above directed, it will be ready in bloom to make your bed quite full of bloom next day or the selfsame day as you pull up the annuals, and you may discard them any day they look seedy, or going off. Another thing is in their favour:—seedlings of the *Antirrhinum* flower in a few weeks after they come up, and they will transplant all through the season; so that you can have a bed of them of one colour, or of many colours; and by keeping each colour in a row or ring by itself, a bed of them makes a decent appearance; or the planting may be all in regular mixture of colours; but that is easier done from first seeing the plants in flower, when any colour or shade that does not please you may go to the common shrubby, or out-of-doors altogether. In October, a bed of *Antirrhinums* comes in as useful as Wallflowers, to plant out for the winter, merely for covering the ground.

Saponaria calabrica, the low-spreading annual which makes the pink-lace bed to the end of the season, will do so just as effectually from seeds sown in the open air as from those in a hotbed; and the first week in April is the best time to sow them. A pot, or a hand-glass, ought to be laid over them at first, and they need not be transplanted out for beds, or patches, till the latter part of June. Then a bed of *Nemophila*, or of *Eucardium grandiflora*, or any other low, early annual, may occupy and flower in the space intended for the lace-plant, or if it is only to be used in patches. It may be sown any time in April, when it will flower. Some of my neighbours here have used it both ways, and it answered as well as it ever did with me with all my force and hotbeds; so that it is a perfectly hardy annual after all.

CHINA ASTERS.

We cannot get them very early without a slight hotbed to get them over the first stage, and now is a good time to sow some seeds for that purpose. It is as auxiliary plants that they are so useful for the flower-garden, as they can be moved from the reserve ground to the flower-bed, in full bloom, about the beginning of August, or a little later, when the great bulk of the annuals which were sown in April are past. The end of April is time enough to sow them in the open ground for this purpose. I used to sow them about the 10th of May, but that was to suit the time I allowed for the other annuals, which I used to sow a fortnight later than most people, to suit the return of the family to the country.

ABRONIA UMBELLATA.

This is a new annual, and one that will flower from June to the end of the season, and requires to be treated in the spring like the blue *Lobelias*; that is, a slight hotbed to get it up, and an airy, cool place after that, till the weather is warm enough to plant it out for the season. It might do to sow it at the end of April, in the open air. It is a nice creeping plant, like the *Verbena*, and with flower-heads in the same style. The colour is a light lilac, or violet, and the flowers are very sweet, particularly towards the evening. It was found

by Hartweg, growing in sand on the sea-shore near Monterey, in California; and now I see it in the seed lists. Also, the very dwarf *Coreopsis*, which I mentioned from Claremont last summer. This is a wonder; the species being from three to four feet high, and this form of it hardly six inches, but very close and bushy, and full of flowers, which are as large as those on the old species. Some people speak well of the new annual *Calceolaria chetonioides*, but from what I saw of it in 1852 and 1853, I would not prize it much. I think it is more suited for damp, shady places, where the sun gets little hold of it.

TAGETES SIGNATA,

though so called in some lists, is the same as I often spoke of as *tenuifolia*. It does best on poor, dry soil, and is the last annual to yield to the frost; it will also transplant from a seed-bed in the open ground as late as the middle of July, when it is coming into flower; and in September it is the most flowery of the annuals.

The beautiful *Sphenogyne speciosa* does well only from the end of May to the end of July to be in flower; and from the first to the end of April is the only time to sow it. The *American Groundsel* is only good from cuttings; although they offer seeds of it, they are not worth having for a gift: they come in like single Daises, and have little colour.

SALPIGLOSSIS COCCINEA,

as it was called, makes a very fine bed in a dry season; but the colour is a reddish-yellow, and it grows up a yard high, or more, and looks remarkably well in a mass. The beginning of April is the time to sow it on a slight hotbed, and to get more air as soon as it has four leaves. The very same treatment would do for the different varieties of *Thunbergia alata*; or they might be sown across a very slight temporary hotbed, and the glass to be taken off all day as soon as they are up. This is the easiest way I know of to get up half-hardy seeds; and any one, who ever saw early radishes grown on a hotbed, could manage a seed-bed in the same way—or rather in two ways—one, by making a common dung-bed, and the other by making a hole in a spare piece of ground, a little longer and wider than the frame, and eighteen inches deep, and filling it up with hot dung till it was higher, by six inches, than the regular ground, then to bank up earth all round it after putting on the frame, then a few inches of fine-sifted soil, and to sow the seeds in rows or circles in this top soil, then a slight watering, and on with the glass; and little more is needed but to watch for the coming of the seedlings. This is the easiest way in the world to get up lots of seedlings with very little attendance, only a slight watering now and then, and to mind to give the bed plenty of air as soon as the seedlings appear above ground, and when they are all up to take off the glass every fine day, after breakfast, and to put it on at night till all danger of frost is over. Now, about the *Thunbergias*; what I was going to say, is, how well they do out-of-doors, in sheltered places, treated like Sweet Peas, as I saw them, in 1852, at Claremont, where they ripened seeds as freely as Sweet Peas, along in front of one of the plant-houses. The grand secret is, to get them up early in April; not to coddle them, but to bring them up hardy, and to plant them out of nursing pots about the end of May, or as soon after as the weather promise to hold on fine and steady.

CENTAUREA CYANEA.

A pinch of this blue Corn-flower ought to be sown in every garden in the kingdom, if only for cut flowers for the mantlepiece; it is next to the *Mignonette* for long standing; and there is a white variety of it, also a grey one, and a dull pink, with other shades,

and of all plants, these are the most easy to learn how to make proper nosegays with: for we must be told, now and then, that we are as Red Indians in this branch compared with the French. There is not one out of fifty, in all England, who can put five different flowers together without *lumping* them. We are the best growers of all the nations; but the taste for making beautiful nosegays for the hand, or in arranging flowers in the rooms, is only on the threshold in England at the present day.

It was mentioned once, in THE COTTAGE GARDENER, that *Martynia fragrans*, which is so difficult to get up, has been found to vegetate out in the open air much better than in pots; and some one told me lately, that by filing off or cutting the hard shell of the seed with a sharp knife, so as to see the kernel, was a good plan to get it up in pots like other seeds. It is certainly a plant well worth growing for cut flowers, and as a single plant against a wall, or in a mixed border. *Viscaria oculata* is one of the very best of annuals; but except in large places, I do not find it anywhere, and few know it except regular gardeners, which surprises me, as if you only east the seeds in the open border you have it up in abundance, and no trouble.

One of the most useful annuals we have is the *Brussel's Sprouts*, and the last Saturday in March is the best time in the year to sow it, for those who, like me, want to cut and come again; but, as they do not want it for flowers, it is out of place in my list of odds and ends.

DELPHINIUM SINENSE.

This Chinese Larkspur is the most useful kind of all the Larkspurs, yet no one advertises it or even mentions it in lists. We have "splendid" this, "splendid" that, and splendid everything you can think of, and "splendid" puzzles to the bargain, and we shall probably, in a year or two, have *splendissima* in Larkspurs, and yet there is not a seedsman in England, or in Europe, who can furnish you with a packet of true blue annual Larkspur; and what is more splendid in a Larkspur than true blue, if you could have it. This Chinese Larkspur is true blue when it comes true to itself, which it seldom does without great care; then it is a hardy perennial plant, which any cottager can keep in sand over the winter, like carrots; it is also the best blue flower for a whole bed of all the blue plants in England, and it flowers from June to November, and is no more than 18 inches high; and yet, if one of our readers want to have it, he must write to the Editor, as if the Editor of a journal like this could find time to attend to a seed-shop. I may here, once for all, say, in plain English, that none of us who are connected with THE COTTAGE GARDENER can possibly give any information about where any particular plant or seed can be had, except Mr. Appleby, who is now on his own account in the trade; as for the rest of us, you may just as well write to Sir Charles Napier for a Larkspur, or Blue-bottle, or anything in the trade; and what is worse than all that, when we, the said writers, see such questions, we are but too apt to slight the other questions in the same letters; and if one of us wrote to the Chancellor of the Exchequer about this income tax, and, in the next sentence, asked him if he knew where we could buy such and such gloves, we could only expect to be paid in our coin—to be slighted in our turn.

THE LAST WINTER.

There is one very particular question which we all wish to have answered as fully as can be before the spring is out, and that is, a full and particular account of all the trees, shrubs, and bushes, that have been killed or half-killed this last winter. Also, what bulbs stood it with such and such protection; and here is an answer for two plants of doubtful hardiness from my own garden.

I bought a good-sized plant, from Mr. Jackson, of the *Stauntonia latifolia*, from India, and I divided the roots, so as to make three plants from the one: this took some time in nursing, and it was the end of last June before I could get them planted out, so that they did not grow more than a few feet before the end of the season. I gave them no protection whatever, and they are not the least hurt; they lost a few inches of the turning tops and that was all.

The next plant which I am desirous to see more cultivated is the "Tree Potatoe," or *Solanum jasminoides*. This climber I planted in 1852, and the winter before last it had no covering, but this winter I had the first six feet of it well protected with straw and a double mat. All the young wood it made since last August is killed, but the main branches are quite safe up to ten or twelve feet, so that it is, practically, quite hardy—more so than the common *Passion Flower*—and no plant better deserves a wall.

Cobaea, *Lophospermum*, *Maurandias*, and *Eccremocarpus*, I could not keep with a good covering, and yet I know a plant of *Eccremocarpus* that was only covered the length of one mat, and the branches which were quite exposed above the mat were in leaf before the middle of last February, but it is in a very sheltered corner, near a stack of chimnies, and no doubt the warmth of the bricks saved it. *Viburnum macrocephalum* I lost altogether; but it had no covering, and it was never a healthy plant. The tubers of *Tropaeolum tuberosum* died in the ground, and rather deep. All my *Fuchsias* stood well, with a single net over them; and none of my half-hardy bulbs are hurt.

D. BEATON.

CAULIFLOWERS.

WHERE due precaution was not taken, the severities of an early winter have decimated the Cauliflower plants not sufficiently protected; where such has been the case, those remaining will be doubly valuable in consequence of the scarcity. Now, it not unfrequently happens, that in addition to destroying a great number, severe weather also injures, to a serious extent, those which may be left alive. This, however, ought not to have been the case this season; for the early tokens we had of its being so, hardened and prepared plants to endure it. This preparatory state of things is one of the many beautiful provisions of Nature, whereby she sweetens the bitterness of her wrath; and although, at the end of a very severe winter, or, it may be, the conclusion of a frost of unusual hardness, we may have to mourn the loss of many of our favourites in the flowering plant way, those of a substantial kind are equally amenable to the same dire laws and suffer accordingly. Though the month of December and the early part of January were more severe than they usually are, yet we have all seen a great deal of injury done by a very moderate frost in March after an unusually mild winter; added to which, it often happens that mild weather is often moist, and that healthy pulverization of the soil cannot take place without the aid of frost, or those dry, mellowing winds we sometimes have in March; so that as far as cultivation is concerned, and, certainly, all that is connected with an annual or hardy perennial growth, a sharp winter is useful rather than otherwise.

The severities of the winter have, also, I believe, injured, if not annihilated, the great bulk of the Broccoli and other greens cultivated in many of the midland counties, which it seems to have visited with more violence than the mere southern; and amongst the general wreck of things, the Cauliflower plants have not come off scathless; but some have escaped, and some careful hands have preserved the whole, or nearly so, of their stock, and what to do with them seems to be the question now

asked. The demand for them from neighbours and others far exceeds the supply; nevertheless, something must be done; and as the weather, since the snow left us early in January, has been all that could be wished for, in the way of pulverizing and sweetening the ground, there is a fair prospect of the latter being in better order to receive plants and seeds this spring than was the case last year and several years before it; consequently, the artificial means sometimes adopted to make it suitable to the well-being of plants are the less necessary; but supposing a quantity of Cauliflower plants, in hand lights, (having moveable tops) to have been saved, and present a fair proportion alive and healthy, no time must be lost in thinning them out so as to hasten them on. This is, to all appearance, an easy undertaking; and so far as the manual labour is concerned the operation is quickly performed; but, then, is it always well done? Numerous instances attest the contrary; for it does not always happen that sufficient care has been taken to inure them to bear the parching influence of an east wind or frosty night, consequently, they are in a poor plight a day or two after being turned out; for often eight or ten plants stand huddled together all the winter in a common hand-light, not more than twenty inches square, or so, and the latter part of the time they make some growth, so as often to fill the space in a crowded manner with their foliage. Then the too anxious cultivator, wishing to have a few fit for use at the earliest possible day, is as careful in seeing them covered up at night, at this advanced season, as he was in mid-winter; this state of things, so widely at variance with the nicely-balanced course of Nature's operations, induces a degree of delicacy into their habit or constitution, whereby they are ill-prepared to meet the cold, chilly currents of air they must endure when planted out singly. This evil is, of course, much increased when sufficient care has not been taken in removing them; but it is at all times attended with a check.

The best way to obviate the evil above noticed is to have the whole of the plants uncovered some days before planting-out time, and the covering left off at nights too, unless on special occasions of severe frosts or other reasons, and the ground being ready to receive the new crop, they must be taken up with as large balls as they can be moved with, and carried at once to their new abode, and then planted carefully; and if it be a bright, sunny day, a flower-pot might be inverted over each, or some other protection in that way. Observe, that in planting, due care must be taken that nothing but the best and finest earth comes in contact with the root—the fine, mellow portion found at the top, after the ground has lain awhile exposed to the action of the elements, is certainly the best.

In addition to this, great care must be taken to get the plants up with as large an amount of earth as possible—a spadeful to each, when they are only to be removed a few yards, is not too much—the hole being made to receive them beforehand; and if the hand-lights have been standing on ground where it is expected a portion of them will remain for good, it is necessary, in the first place, to select some of the best to stand in each hill. This must be regulated by the size the hand-lights are, the distance they are apart, and other considerations; but, in a usual way, about three is as many as can with propriety be left, and much oftener only two remain; but so many objects regulate this that it must be guided by the wants of each case. Commonly, private families do not care so much for a large Cauliflower, preferring a small or medium-sized one instead, consequently, the plants may stand somewhat closer; but in whichever way the operation is performed, it is advisable, when the thinning is completed, or when part of it is done, to dig and dress the ground around those remaining, and to replace the hand-lights again for a

time, if they be not wanted elsewhere. This will enable the plants to push on, and prevent them receiving that check which the withdrawal of their companions would effect.

When Cauliflower plants have become too far forward early in winter, they very often start up into a premature head, or what by gardeners is called, "buttoning." This is caused by the seed being sown too early; for then the plants, endeavouring to keep pace with other of their brethren in the "Spring Broccoli" way, rush up into flower at the end of March, or soon after, presenting heads, as the term implies, not much larger than a button; this cannot well be prevented; a good thinning, and culture in the way of encouraging a sturdy growth, will partly prevent it; but it is difficult to stop Cauliflowers from "bolting," in the south of England, which are the produce of seed sown before the last week in August; while most people wait until the first of September. Whichever way it is, the last sown ones are generally most to be depended on; and a second crop that may be standing in a frame in some sunny place will often contain more good plants than the earliest batch which have been more attended to during winter; and this second crop must have all the attention paid them now their worth deserves, and they will, doubtless, repay it; for we hear of heavy losses in that way the past winter; and the autumn was anything but a good one for raising seedling plants, &c. The heavy and continuous rains had so cooled and soddened the earth that but really little warmth remained in it. However, as the spring, so far, has been exactly the reverse, it behoves the careful cultivator to turn such a change to good account, and a few early sown Cauliflowers, sheltered and forwarded by glass, or other protection, are doubtless going on in such a way as to give just reason to expect that the regular succession and production of nice heads is not likely to be interrupted for some time yet; and as Cauliflowers, and their almost synonymous White Brocolis, form important features in the general bill of fare for the year, the propriety of neglecting nothing that is calculated to command these necessaries need not be urged.

J. ROBSON.

CUCUMBER AND MELON PIT HEATED BY FLUES.

"As I wish to erect a small pit for growing Cucumbers and Melons without the annoyance of huge piles of dung, perhaps you will be good enough to inform me whether I may expect any success with a structure such as I have sketched on the sheet annexed?—F. E. R., *Oxon.*"

I THINK the plan, of which a drawing is on the next page, is worthy of prominent notice, not only as keeping us in mind of the old flues, but because the consideration of the subject may enable us to give a suitable reply to many enquirers, who, out of various modes described, may thus be enabled to pick out what will suit their circumstances best.

1. I believe that the above plan would answer if the pit were suitably built, and the plants afterwards well-manned. I observe no striking error in the whole arrangement, though, so far as I am aware, the only novelty connected with it is the large pan of galvanised iron set upon the top of the flues. I have had no experience how long such a pan, from four to five inches deep, would last in the circumstances, but my impression is, that when finished, the whole affair would be more costly than a tank or hot-water pipes. There can be no question that such a pan would yield a requisite amount of vapour.

2. There is nothing very pleasing in the huge mounds of dung, unless at Celery and Cauliflower planting

time; but yet, in country places, these hotbeds often give just the suitable preparation for the kitchen and member, that to keep a temperature of from 65° to 70° in cold weather costs no little amount of fuel, though I readily grant, that for a place of the size detailed above, there is less real waste of fuel by such an application of flues as could be secured by any mode of hot-water without flues. Any one who is doubtful of this has only to put his hand on the chimney where a hot-water apparatus is at work in a cold day, and to do the same where a similar heat is maintained by a flue of some fifty feet in length.

3. The only difficulty I ever experienced in growing Cucumbers and Melons by flues, with nothing like such a nice evaporating-pan as the above, arose from deleterious gases finding their way through the joints of the flue, especially when all sorts of rubbish were used for fuel. I have had boxes of Cucumbers in full bearing in March, and looking splendid at ten o'clock at night, that in the morning had nothing green about them but the fruit. The flues were rather old and rickety, and an explosion had done all the mischief, though there was scarcely the smallest crack perceptible. To guard against such a contingency, I would strongly advise twelve feet of the flue nearest the furnace—as much more as might be resolved upon—to be built with brick on bed, instead of brick on edge. It is true, that such a flue would not be so easily heated, and, therefore, would not be suitable for a greenhouse, where, in general, sudden heats are chiefly wanted to meet sudden frosts, but strong continuous heats are wanted for such plants as the Cucumber if forced at all early, and, therefore, though the thick flue does not heat so quickly, it retains the heat longer, and nothing is, therefore, eventually lost, while a more uniform temperature is maintained, and danger from explosion of gases reduced to a minimum.

4. Supposing, then, that it is resolved upon to have such a pit, is the one indicated suitable in size? Taking it at five feet in the clear, I presume the front-wall is intended to be about three feet nine inches, and the back-wall close upon five-and-a-half feet. Now, allowing fifteen inches of soil, though Melons would enjoy three more, and fifteen inches from the soil to the rafters, which would make, with six inches more for slate and rubble drainage, three feet in all, there would be required at least two feet more for chamber, so that, at the least, the front-wall would require to be four feet nine inches, or five feet, and the back-wall six-and-a-half feet in height, or six feet would do, if Cucumbers were wanted only towards the end of April, and Melons in June and July. If we did not go even higher than six-and-a-half feet, the reason would chiefly be for the saving of brick. The chamber could not well be less than two feet in depth, and if perfection was desired, one-and-a-half feet more would be better still, as then the heat would be more softened, and loaded with vapour before entering the house. I once had to do with a splendid, most expensively-built Cucumber-house; the produce of which I have never seen surpassed—but more than double the width of the one under consideration. It was heated chiefly by flues in a chamber, and others that gave surface-heat. The chief peculiarities were two. First, the chamber was so large that a person could walk along it stooping. The second was, that a boiler was placed over the furnace always supplied from a cistern and half-cock. This boiler had a pipe attached to its

flower-garden, and, therefore, the produce costs little but the labour; but let all heaters of pits by fire re-

- A. hot air chamber covered in by a layer of slates, then "creeks," &c., &c., and, lastly, soil i.
- B. and C. flues, "flow and return."
- D. pan of galvanised iron full of water.
- E. opening for cold air near the ground, which after being heated and moistened passes into the pit above the soil, by a series of drain-pipes, F., then up, and finally out at tilted sash G.
- K. series of drain tiles to admit cold outer air on favourable occasions.

Pit to be five feet wide in the clear: length twenty-four feet; flues and pan running the whole length. What will be the most desirable height and dimensions of hot-air chamber? and pit?

top, three or four inches in diameter, and some four feet in length, from which, in proportion to the heat of the fire, steam was discharged into the chamber, and then there were plug-holes for letting this mild vapour into the atmosphere of the house at will. I know of several imitations, but in no case was the success so uniform, and that chiefly owing to false economy in having a chamber not the third of the depth, and, therefore, the heat and the steam were apt to burn and scald tender plants. There would not be quite so much danger in the present case owing to the pan of water; but a moderate depth of chamber would admit of the flues being examined without interfering with the covering. In fact, without this pan of water, the slate covering would have required to be some twelve or eighteen inches, at least, from the flues, to prevent the risk of its cracking and breaking. The moisture would greatly prevent that. If covered with flag-stone, there would not be the same danger if placed near the flue.

5. The mode of giving air at E is much to be approved of; also at F, though of less importance there, as, when the weather is fine enough to demand abundance, the sashes could be tilted there without any disadvantage. The advantage of the openings at E is, that the air of the house may be renovated without greatly cooling it. Openings, similar to E, should be placed close to the back wall opposite, and then, though the opening at E were stopped, the air in the house, after getting cooled, would pass more easily through the chamber again to be heated and moistened. Plugs should be furnished for E, as, if the place is to be heated economically the openings must not be liberally used in severe weather. The openings E, front and back, should be in the centre of each light; and these, too, should be furnished with plugs to shut in the heat in the chamber when desirable. For instance, if you find the heat of the soil not quite so warm as you would

wish—a sunny day gives you plenty of atmospheric heat—put in the plugs, and the heat of the chamber is thrown into the slate and soil.

6. *Walls.*—I suspect there is an intention to have nine-inch walls as far as the flooring, and five-inch walls above that; but this economy in bricks will be attended with no economy in fuel. I should prefer, for an early pit, a nine-inch wall throughout; better still, a nine-inch hollow wall; and best of all, a fourteen-inch hollow wall. I need not now repeat what was said of confined air as a non-conducting medium. I have a pit used for similar purposes with a nine-inch solid wall, four feet six inches at back, and above the ground level, and one foot eight inches in front. Notwithstanding protecting the glass with straw covers, the loss of heat, by the back walls especially, was a serious affair, where the carriage of coals adds from a full third to a fourth of that for which coals may be had by those near a railway or wharf depot. I covered that wall with a couple of inches of wheat-straw tied firmly and neatly on; and if any one wishes to know how much heat is thus saved, he has only to insert his cold fingers beneath the straw, in a cold day, and the warmth of the wall will give him an idea of the loss that would otherwise have escaped by radiation. That loss would be greatly ob-

8. Some years ago, I had several pits heated by fermenting matter, inside and out. I hardly know how deep the walls were, for never having enough of matter to fill them they were never thoroughly emptied. The banks of manure, in the shape of livings, kept me ever on the move for fermenting material. An idea of the unsightliness of these mounds, coupled, very likely, with the intention of shutting me out from access to fermenting matter, led to these pits being heated by hot-water, and as they were also increased, I had no reason to grumble, though visions of poverty-struck vegetables began to flit before my mind's eye even then. Well, the pit I have already referred to, four-and-a-half feet at back, and twenty inches in front, above the ground level, is the highest of three ranges, each rather more than fifty feet in length, heated by one furnace, and to which three ranges, I hope some day to have a fourth, with a pipe to keep out frost. The pit, originally, was even flatter than the one of our Correspondents; but, as a new wall-plate and new sashes were needed, we gradually lowered the front wall, so that everything inside is very easily examined, and a fair amount of sunshine is thrown in. Now, I would have wished to have sunk the pit considerably back as well as front, but it so happens, that though we have a deep well in the chalk, we are liable to be flooded-up in thunder rains; and as I know that every foot I sunk the pipes for bottom-heat, I must also sink the stock-hole, I did what I considered the best in the circumstances, and fixed the floor, No. 1, so high as would enable me to grow Cucumbers, &c., and fair-sized pot plants of anything. The pit, therefore, was filled-up with clay and any earth handy, well-rammed, and then covered with two or three inches of concrete, well-smoothed on the surface, and then covered with a little fresh lime and sharp sand, so that when dry it was quite hard and smooth, and, as I expected, next to thoroughly impassable by water. This was fixed a couple of inches or so below the pipes; and as the stones, brick-bats, &c., are placed as open as possible, and then terminated by finer gravel at the top, the pouring-in of water at the front of the pit, either through a funnel, or else to the wall, inundates this floor, and supplies, at will, a moist bottom-heat. Fine evaporating pans are placed on the front pipes for top-heat. I used a trellis for this pit last season. For the

viated in the case of our Correspondent, and the pit in every way, be more manageable if instead of standing above the ground-level, fully one-half, at least, of the walls were sunk in the ground. The only difficulty in this case would arise from water, as the bottom of the stock-hole would require to be at least two feet deeper than the bottom of the flue. The air openings at E might just be the same, a pipe being brought up above the surface-level.

7. Now, though the flue system will secure, perhaps, the most of the heat from the fuel, still, it can neither be so equally nor so safely diffused as by hot-water, either in pipes or tanks. By either of these modes, Melons and Cucumbers may be grown in pits some three feet deep in front. A great depth of walls, and consequent brickwork to secure a chamber, would thus be avoided. And, therefore, though I have offered the above remarks on the plan of our Correspondent, yet, knowing that nothing suffers so much from the escape of gas from a flue as Cucumbers and Melons, I would strongly advise, before building such a pit, to compare the expense of flue and iron pans, with extra brickwalls and the hot-water system. To enable him to do so, I will mention some modes adopted here, and what has been done elsewhere.

- A. bottom of bed, consisting of concreting, laid firmly on rammed clay, F.
- E. three-inch water-pipes for bottom-heat, surrounded by clinkers, old brickbats, &c., with fine clean gravel on C.
- C. soil for Cucumbers and Melons.
- D. trellis.
- E. three-inch pipes for top-heat, with zinc evaporating-pans.

second pit, as the walls are not so high, the Vines were generally trained on the ground; but Cucumbers or Melons are only one or two of the numberless purposes to which these pits are applied. It will, at once, be seen that there would be no occasion to have a wall any deeper than the clay or concrete bottom, and fully half of that might be sunk. The pit is almost six feet in the clear.

9. No. 2, is the same pit which I modified this last winter. I used to grow winter Cucumbers in the Pine-stove, and when, some time ago, Pines were discontinued, it was desirable to have Cucumbers in a lesser place, so as not to use much fire in winter. I grew them, therefore, in No. 1, but I found that they often

wanted a little attention, when, owing to the weather, it was impossible to give it to them; and there being little opportunity for working the syringe on the under side of the leaves, they were kept clean with more difficulty. I resolved, therefore, to change No. 1 into a small house, No. 2, by digging out a path fifteen inches wide at the back, increased to some twenty inches for elbow room, having a small eighteen-inch door on the ground level in the back wall, for popping in, and nothing could answer better. They who have grown fine Cucumbers in pots will at once perceive that even by this narrowing of the soil space there is ample room left. The sinking of the path cost only the labour of removing the soil and building a four-inch wall, as far as the top of the soil, as the back wall was existing previously. In making such a pit, though a back wall some seven-and-a-half feet would be wanted, there would be no occasion for sinking the front wall lower than the flooring.

G. path-way cut out at back, to enable all work to be done inside in wet and cold weather.

H. Strawberry shelf.

Here (March 14) Cucumbers and Strawberries are alike fruitful and luxuriant.

the centre. The trellis consists merely of a few rough spars of wood, nailed together, the size of a light, and crossed with string and wire. The only objection I have heard urged to this arrangement is, that when it is desirable to use such places for plant repositories, the space occupied by the path would be next to lost; but I do not see the force of the objection, as tall plants might be placed there, and if not wanted for that purpose, boards on a stage could be thrown across for setting smaller plants on. Again, for early work I could not hardly improve on the present arrangement; but if Cucumbers were not wanted before the approach of May, two four inch pipes, surrounded with rubble, with openings back and front to let the heat up, would be sufficient for both bottom and top-heat in a five-foot pit.

10 If a tank should be considered preferable, one four inches deep, of iron, brick and cement, or wood, would obviate the necessity of high walls, unless a path-way was desirable, as in No. 2. I do not think that the cement for a tank in such a pit as our Correspondent's would cost a great deal, and the bricks required for flue and chamber would be more than sufficient to build it. Any person, who has ever made a brewer's cooling-tank, could say for what a wooden one could be obtained for, and that three, four, or five feet wide, four inches deep, divided in the middle, and covered with slate, would give as much heat as he would know what to do with, provided there were six inches of open rubble over the slate, and openings round, for the double purpose of pouring water in to command a moist heat, and to let that heat into the atmosphere. I see, the other week, enquiries as to patching and securing such a wooden-tank to make it hold water, but if properly made, and well beat at the joints, and red-leaded at the joints, there will be no difficulty in this matter, and no need of any covering or coating whatever; as when once filled, and kept full, the continual swelling will prevent everything like leakage. I do not know how long such a wood-tank would last, but I know of some that have been in use fifty ten years,

and are now as good and sound as ever; and that I partly attribute to banishing every painting and smearing substance from them.

11 I would strongly advise every amateur, before commencing to build this season—as economy with him must ever be a principal motive—to turn back to the section given, page 337, in No. 52, the last number of the second volume, in which it is shown how a compound of pit, forcing-house and greenhouse, are all heated by a small wooden-tank, heated by a small boiler, with two iron flanges, the communication with the tank being kept up by two leaden pipes. I do not think I ever saw such an economical arrangement. I popped my head in this house about a month ago, and the sight was a very tempting one. I wished particularly to notice—the state of the one-and-a-half-inch thick boards, composing the sides of the boxes, acting as pits; and, thanks to the arrangement of not allowing the earth to touch them, and to their being merely planed, and not painted or smeared, they, as well as the tank, seemed as fresh as the day they were put up.

So far as I recollect, there was something very suggestive in the whole progress of this house. I believe a pit was to be heated with this tank with the assistance of dung-linings outside. The heating power was found so great that the linings were not merely dispensed with, but the walls of the pit were removed, and the boundary-walls of the linings being raised were made the walls of a small house, with a narrow path round the tank. Still, there was plenty of heat and to spare. The back wall was therefore lowered, glass sliding-sashes substituted, and a nice little greenhouse placed at the back, so that the roof of both places has one uniform slope. In very cold weather the greenhouse has at once the necessary temperature by sliding a few of the sashes.

12 Neither in the houses heated by the above wooden tank, nor in the pits No. 1 or No. 2, have I described any mode for heating the air before admitting it into the house, as so properly alluded to by our Corres-

pendent. The fact is, I give but little air in cold weather; and when very cold, a small quantity keeps up a healthy circulation. Were I close to a coal pit, I would use means for carrying-out our Correspondent's idea on this subject as far as possible. With a rather low temperature at night, there is less danger from a high temperature during the day. Circumstances must, therefore, often regulate our practice. For instance; I have seen splendid Pines, that were grown and especially swelled with a minimum of air, having a high temperature in sunny days, and with but little heat in pipes or flues. I have seen as fine fruit on stabbier plants, where air was given in abundance, though to give that, the heating apparatus was hardly ever out of use, even in summer. This abundance of air yielded more returns from the stubby habit, in a certain number of feet; but, of course, against this was to be set a considerable extra amount for fuel, a matter of less moment where that necessary of forcing or growing tropical vegetation is plentiful and near at hand, but a matter of great importance, where, owing to circumstances, the fuel bill is a heavy item for gardening expenses.

R. FISH.

ALLOTMENT FARMING.—APRIL.

As our old almanacks had it—"with the farmer and the gardener this is the busiest month in the year;" and, indeed, it is equally true now as a hundred years since; but we may add, that since those days, although April occupies the same position still, the other months do not; they are every one much busier months than their predecessors, owing to improved practices, together with an extension of objects.

It may fairly be averred that *the chief foundation of a successful gardening year must be laid in April*. Any dawdling or neglect in this month is perfectly irremedial. Therefore, let us beg of our readers to spare no pains whatever, to permit no excuses to come between them and their plans. In the language of that Book of books, the Bible—"Whatsoever thine hand findeth to do, do it with all thy might." Surely, the past long and necessitous winter will have taught thousands the immense importance of a previous summer's perseverance. These industrious workmen who plod with all their might in their allotment or garden, and who live near to the sluggard, will have had ample proofs this winter of the vast benefits accruing to a family through the industry of a good father. They would, in the darkest and coldest night, amid the howling of the wind, and the battering of the tempest against their windows, look back with a secret pride and joy on the labours of the past summer—plainly attested by the snug fire, with its kettle of useful roots steaming away for soup or other compound. Again, then, let me challenge every reader to screw his courage up, and remind him that his own family, as well as his country, expect that he will do his duty.

Now let us see what are the chief things for consideration at the beginning of April. Mangold, Swedes, and Carrots, must be first thought of, and I suppose I may add Potatoes. Root-crops, as winter stores, are always with me a first consideration. Next in order comes the providing plenty of Greens, and the various Cabbageworts to be introduced, chiefly in mixed cropping for autumn and winter use, or for sale. These two points secured, the rest is composed of smaller matters which cannot be easily grouped, and which we will simply point to.

I spoke, in March, of the preparation of the ground for these *root-crops*, and may fairly suppose, that with the excellent spring weather which the kingdom in general has experienced for several weeks, that little work of this kind is in arrears. Nothing but sickness can excuse an allotment-holder for such neglect. To those who are behind, we say, if the ground is tolerably dry lose not an hour in getting root ground ready; and if very stabborn, and in a neglected state, you had best ridge it for three weeks, and then, seizing a dry time after this small fallow, break it well down with the fork.

I should say, that as a general maxim for allotment holding, the gardening of cottagers, &c., from the 15th to the 25th of April is the best *Mangold-sowing* period; and for *Swedes to grow where they are sown*, from the 1st of May to the 20th. However, these periods, in which considerable latitude is given, must be ruled, in some degree, by the condition and character of the soil and by the weather; for admitting, for argument's sake, that Swedes or anything else *should be sown* on the 20th of May, wiser would he be who sowed on the 30th, with his soil in good trim, than he who sowed on the 20th, on an ill worked soil, and in bad weather. This argument applies to nearly every crop we have to deal with.

Swedes, to transplant after Potatoes or other crops, must be sown according to the period in which they are wanted, although, it may be observed, that if they can be grown very thin in the seed-bed, they can scarcely be too soon sown, as they transplant well when they have bulbs as large as a duck's egg. They should, therefore, be sown in drills for transplanting, and thinned in the drill; they will thus be capital plants, and with good management may equal those sown to remain, and thus an extra crop be obtained the same season.

Care must be taken to avoid *mildew*, to which this crop is so liable; and in order to guide our readers as to a preventive, I must advise them, that whatever tends to check the plant whilst in the middle of its growth, say during July and August, has a tendency to produce mildew; therefore, badly-worked soil is one of the chief predisposing causes; such soils are more liable to be affected by droughts, and, moreover, offer much impediment to a free extension of the fibres. Deep, well-worked, and well-manured soil, therefore, for the Swede.

Carrots.—The larger kinds should be sown at the end of the month, if the ground is in fine order, otherwise they may be got in any time before the third week in April. Many of our good growers are partial to late sowing; they say the chances of the grub are lessened; and I do think there is truth in it. In addition, the Carrot, when young, is a most tender thing, and means ought to be taken to ensure as rapid a growth as possible when above ground. It is slightly impatient of frost, and ought not to be above ground before the second week in May, by ordinary culture. Here, while speaking of rapid growth, let me again refer to *the compost* so often pointed to before. I am using it to almost every crop. My mixture is as follows:—Peruvian guano one part; burnt or charred ashes three parts; soot four parts; and old rich manure, like black mould, four parts. This is all *thoroughly mixed*; much pains is taken in this proceeding, and it is applied liberally by hand. All my root-crops have a little manure dug rather deeply in, and the dressing with this compost applied with the seed; and my object is twofold, viz., to establish the young plant *quickly*, and to provide a rich and moist medium at a level beyond the reach of droughts, when the plants should be enlarging much in bulk, say after Midsummer.

Potatoes, if not planted, must, of course, be got in immediately, and what little manure is used, let it be old and mellow. Our readers may refer to other advice in the number for March.

Winter Greens.—Nearly all that class of vegetables called Cabbageworts, must, as far as concerns the allotment holder or cottager, be sown during April. The following I recommend, and their importance is indicated by the order in which they are placed:—*Green Kale*, *Brussels Sprouts*, *Savoy*, *new Cabbaging Kale*, *Sprouting Brocoli*. I have left out *Cauliflowers* and the ordinary *Brocolis*, as they are more of a luxury than profit, unless grown for market purposes. *Cabbage*, too, forms an exception; those of a dwarf, compact kind, should be sown monthly, beginning in March and ending in August. Two general sowings, then, should be made in allotment gardens of these *usefuls*—one in the end of March, or beginning of April; the other about the 24th of April; these two will, in general, serve to meet every reasonable demand. Those who wish to have *very large Savoy*s, *Kale*, &c., may sow in the second week of March, but they must lay their account with having to "*prick them out*," as gardeners term it. I, however, think that much of the time employed in these extras (which just serve to astonish for a moment, or cut a dash at our exhibition-table), would be far better employed, in these needy

times, in deep delving, and other such processes as serve to bring much profit without extraordinary display.

About *Lettuces*, *Spinach*, *Kidney Beans*, a *Cucumber-bed*, &c., I think I need say little; our readers do not require amplification on these nick-nackerics every day. I would rather address myself to the question of *profit*, for although it has been the fashion to cry—"a good time coming, boys;" a cry engendered by the high amount of commercial prosperity which has taken place through the blessings of peace; yet, I should now urge that this cuckoo cry be laid aside for awhile, and say, there is a serious time coming, boys. Leave off dreams and visions about luck; and fall back on that kind of moderation in desires, perseverance, industry, and simple and single-minded trust in Almighty God, which have characterised the truly great and good in all ages.

High culture must now be the aim of all who would have a good garden; the fork, the hoe, and the spade, must be kept a-going, and a judicious forethought exercised in carrying out such operations, always having regard to the weather. A prudent and diligent manager of a plot of ground will escape much of his neighbour's extra labours, and, at the same time, attain a greater degree of success, by joining a good head to a sound pair of hands and heels.

Let me here repeat advice about the *manure-heap*. This is no trifling affair with any cultivator of the soil; certainly not with the cottager. My advice is this: never let your manure-heap get hot—warm but not hot—say about the heat of new milk. Never let rain enter and pass through it like a colander, or steep it. I remember, when a lad, hearing a lark of some sailors, who, in the days when tea was beginning to be used in England, took a fancy to try this outlandish thing. They boiled it, strained it, and after pouring away the liquor dished up the tea-leaves with pepper and salt. They thought it poor diet, as well they might. I much fear that many use their muck-heaps little better.

R. ERRINGTON.

APIARIAN'S CALENDAR.—APRIL.

By J. H. Payne, Esq., Author of "The Bee-Keeper's Guide," &c.

WITH the present month the apiarian's anxiety for the preservation of his bees will, in a great measure, cease, for where any are alive and in health, it must have been by the most careful attention in feeding, &c. The mortality has, indeed, been very great this winter; many persons of my acquaintance have lost *all*. I am happy to say that I have not been so unfortunate, for I have at present three out of fourteen alive; but, perhaps, the most trying time is now approaching, for the bees are aroused into activity, and the population is rapidly upon the increase, that should a week or two of cold wet weather set in, the few that are left will be in great danger, unless well-supplied with food; and at this time I would say that barley-sugar is the best.

POLLEN.—The whole tribe of Crowfoots are now making their appearance, all of which are eagerly sought after by the bees, but more especially the Pile-wort (*Ranunculus ficaria*), which affords them such an abundance of pollen during the months of March and April, and which abounds in meadows, pastures, and hedge-banks. Seeing an abundance of it carried into a hive is a sure proof that the stock is in a healthy and thriving state; but, let it be remembered, that pollen has nothing whatever to do with supplying the bees with food, for they will die from starvation with the combs filled with pollen, for it is only in the larva or grub state that they eat it; therefore, if the stocks have not a store of honey, go on to give barley-sugar.

HIVES.—It is now time to have a supply of *new* hives for the summer's use, for by no means put a swarm into an *old* hive except it should be one of last year's already filled with clean new comb; this, as I have before said, will be a great help to the bees.

WASPS.—Queen wasps appear to be more numerous this spring than usual; suffer not one to escape. I have been fortunate enough to kill all that I have seen—a good syringe is a most useful instrument for the purpose.

WATER.—Let water be placed in the vicinity of the apiary; at this season it is very important: the bees *must* have it, and if not supplied to them, they will go to brooks or ponds for it, where many of them will be drowned.

GAME FOWLS, AS RECENTLY EXHIBITED.

POULTRY Societies had been for some time established before any high degree of excellence was manifested in their Game classes. Whatever the cause of this falling short in a race of fowls possessing so many good properties, and so generally kept, whether they were regarded, from their contentions disposition, as unsuited to the exhibition pen, or, from motives of a prudential character on the part of their owners, were kept back from public notice, it will probably be admitted, that until the last year or so they have not on such occasions been worthily represented.

Birmingham, however, in 1853, amply redeemed any past deficiencies, and the striking improvement in their classes then effected was also in a greater or a less degree shared by many of the other exhibitions of that year.

In numbers, the *reds* have usually preponderated, and of these, again, the "black-breasted" seem to have had the preference. The plumage of the latter, indeed, presents the most agreeable combination of colour, and this especially in the hens. But too many exhibitors, and sometimes even those who ought to have passed their noviciate, have much still to learn in matching their birds. In this observation, we do not merely allude to birds of the same variety with differently coloured legs, or unmatched in respect of feather, but to the strange, indiscriminate jumbling together of the black-breasted, and the other reds. Surely, in neither sex of these several varieties is there any absence of characteristic distinction that would account for such confusion. The dusky tints of the hens of the streaky-breasted birds and the gingers, are in the strongest possible contrast to the clear light hues and delicate marking of the black-breasted hens, and in the cocks the veriest tyro can hardly err. Yet hardly an exhibition occurs without an instance of such carelessness.

The Game fowl has the widest licence with regard to the colour of its legs. White, yellow, slate and olive, are here all admissible; the preference existing solely in the eye of the different breeders. Our own selection of the white-legged birds may have been influenced by the merits of the celebrated "Derby" strain, of which the white leg was considered an important characteristic. White, or yellow, however, to our own eye, have a decided preference over the other colours. Fault was found at Leeds with a decision that gave a prize to a pen of black-breasted reds, in which the cock had a portion of the sickle feathers of his tail white, an appearance which has been commonly, but erroneously, thought to indicate the infusion of baser blood. But for many generations this peculiarity has been frequently noticed in the Derby strain, but without the slightest evidence of either deteriorated courage, or of deficiency in any of the other properties of the Game fowl. We should certainly prefer not to see it; but at the same time, we would not dwell on it to the disadvantage of the bird.

The *white* and *pile* birds have also been remarkably good; but for such perfection of feather as may gain a prize they would seem to require the indulgence of a good country run, an advantage that many of their present exhibitors would appear to be destitute of. All our enquiries have failed to connect the white specimens to which the designation "White Indian Game" has so often been applied, with any oriental derivation. So far from it, indeed, that they present a marked opposition in point of figure to all game fowls of really Indian origin that we have ever met with; for the heavy, thick-set proportions of the latter are as widely removed from the peculiarly graceful symmetry of the common white Game fowl as we could expect to find in any sub-varieties of the same family. These white birds are, in fact, identical with the "Smocks" of our Midland Counties. The mention of Indian Game fowls induces a remark that specimens of this breed are far from uncommon in the south of England, and around Plymouth, especially, they have many admirers, in whose ranks, however, we cannot consent to be reckoned. The fine clean head, the graceful yet powerful neck, with the extraordinary muscular, but yet symmetrical proportions of the leg of the English bird are all absent; and although we may gain heavier weights, these but ill compensate for an ungainly figure and coarse frame. We are speaking of the Indian Game fowl, properly so called; for in more than one importation from those coun-

tries we have seen specimens with every evidence of unstained England blood, the descendants, doubtless, of some of those birds of which our East Indian, in days of old, had large consignments.

In the *black* and *brassy-winged* classes we have lately had many birds possessing excellent points, in respect of size, no less than shape; they appear, however, to find favour, comparatively speaking, in the eyes of few. The beautiful "Furness" birds of former days, now of rare occurrence, would prove acquisitions to any show.

Our partiality for the black-breasted reds has been acknowledged, but we should be sorely put to it for reasons to confirm our choice, when a really good pen of Duckwings made their appearance, provided always that they are white-legged birds, a condition that harmonizes best with the general tone of their colouring. The perfection of form attained by hens of Game blood, is, probably, as frequently shown in good specimens of Duckwing hens as in any other variety; the delicate character of their plumage, doubtless, adding materially to the general effect.

Of *greys* and *blues* we have had a fair proportion, but not in such form, it strikes us, as would bring them into competition with the varieties already mentioned. As to the *Cuckoo*, the blue clean fowl, and some other eccentricities claiming a Game pedigree, the mere mention of them will suffice for even if their lineage be pure, they are far behind in point of feather.

On a general retrospect of the Game fowls exhibited in 1853, terms of high commendation must certainly be employed, and a manifest advance on the pens of the previous year will readily, we believe, be conceded. But still, here, as elsewhere, there are numerous instances where poultry associations should direct improvement to obvious faults in birds shown in these classes. More especially, indeed, should attention be drawn to the obvious infusion of Malay blood that has so often disfigured pens purporting to contain Game fowls. On more than one occasion, indeed, full half the pens were summarily, but most justly, disqualified on this account; for a single glance is sufficient for passing sentence on the coarse-headed, awkwardly-formed fowls whose parentage is attributable to such a cross. The evils of mongrelism are seldom more conspicuous than in birds thus descended; and there is such an entire absence of any single property, or characteristic (unless mere weight be so considered) benefited by the misalliance, that we are utterly at a loss to imagine the notions that have induced so many breeders to bestow their care on them.

Pedigree has most properly been stated as an essential point in the selection of the breeding-stock of our fowls generally; but nowhere should we be more cautious against any omission of this security for the excellence of the progeny than where Game fowls are concerned. The results, indeed, of crosses with other strains of the same general family, but varying in point of colour, seem very uncertain, both as regards the duration of their effect, and their actual extent and application to the progeny. To illustrate the first case: pile chickens are asserted to have been thrown from black-breasted red birds, carefully watched and guarded against any stain for upwards of ten years; while in some experiments of our own during the last year, Duckwings, perfect to a feather, were bred from a cinnamon hen-tailed cock and a Duckwing hen; and a friend's Duckwing cock, again, with a black-breasted red hen, gave as good a black-breasted red pullet as could have been desired. But, alas! for the unfortunate breeder, who, ignorant of their origin and pedigree, had taken either of their productions for stock, perfect as they appeared to the most critical eye. Hence, however, the manifest explanation of the pile chickens thrown after the lapse of so many years from a black-breasted strain which could have had no intermixture in the interval; although, in ninety-nine cases out of a hundred the disastrous consequences would have been far more quickly brought to light.

Let pedigree, therefore, be enquired into with the utmost diligence where Game fowls of pure race are looked forward to as the tenants of our yard; and this rule may, also, profitably be extended to every other variety of our domestic poultry, though recorded instances may seem to require it more especially in the birds that have been the subjects of this present paper.

THE TANK SYSTEM OF HEATING.

I HAVE just seen your impression of the 10th inst., and find that one of your correspondents wishes to know the best material for preventing the leak in wooden tanks. Now, as I was the first to recommend the tank system,—and my first experiment was with a wooden one,—I think that I may claim to know the best modes, having had a great deal of experience. I should, therefore, recommend your correspondent (*J. M.*) to have the joints ploughed and tongued, with slips running through the plough, imbedded in *white lead*. No water will then run through the white lead, and then four good coats of paint over the entire surface will preserve the wood for many years. I see that you recommend Roman cement, but that will not answer at all, as it will not adhere to the wood. White lead is the only material that will do; and, with proper attention, a wooden tank, well made with good seasoned material, the joints well put together with white lead, and well painted every three years, will last for a very long period, and is by far the cheapest of all tanks. I write this from experience; and if your correspondent requires any further information, I shall be glad to afford it.—WILLIAM E. RENDLE, *Royal Nurseries, Plymouth.*

PULMONARY DISEASE IN POULTRY.

IN February, 1853, I purchased a well-bred Shanghae pullet of Mr. Sturgeon's breed. She did not appear then of strong constitution; and in April last, in consequence of roosting in a cold house, she showed symptoms of disease, exhibited in shortness of breathing and wasting of flesh. She has throughout laid well, and had a brood of chickens about five weeks ago, but has never since April been able to eat dry food without a cough. On Wednesday last, the 21st, she appeared to labour for breath exceedingly; I gave *two teaspoonfuls of castor oil*, and the next day she was much easier. The following day she again grew worse, could not eat at all except the food was placed in her mouth, when she swallowed freely; the fourth day she died suddenly. On the 26th of September I had her opened; the "post mortem" exhibited sound liver and all other parts, except the lungs, which were *totally decayed*, indeed, I may say, in almost a *fluid state*, and on the left side of the lungs there was a bag of solid hard pus as large as the egg of a bantam. I could not have supposed that within four days of death any creature could have walked about and eaten well, as she did (moist food), with such a disease existing in the lungs. It is well to observe that her produce has been fine, but *all* of them exhibit a delicacy of constitution, and *several* a tendency to the same disease.—A WILTSHIRE INCUBENT.

SUGGESTIONS FROM THE GARDEN AND THE FIELD.

By *Cuthbert W. Johnson, Esq., F.R.S.*

(Continued from page 488.)

EARTH AND WATER.

SOME of the uses of the metals and earths of which the solid portion of the globe is composed are evident to every one. They are necessary as a resting place—a habitation for our very existence. The same remark applies to vegetables. The Greek philosopher, in fact, considered that in these consisted all the uses of the earth to organised beings. Chemistry, however, has enabled us to find out that the use of the earths of which the globe is chiefly formed is not confined to their mechanical properties, but that they enter into the composition of both animals and vegetables, as essential portions of their composition. There are only about three earths which chiefly constitute all cultivated soils, all of which are found in vegetable substances. Lime, united with either the phosphoric acid or the carbonic acid, is found in almost all vegetables, and these substances, when consumed by animals, furnish the very materials of which bones are composed.

Equally common in vegetables is the presence of the

earth silica (flint). It abounds, for instance, in the Grasses, in the straw of Wheat; it exhibits itself in such large proportions in the Dutch Rush that the turners use it to polish the hard woods, ivory, and even brass.

The earth's alumina and magnesia (or clay) are also found in plants, but in less proportions than either lime or silica.

One great use of these earths in the composition of vegetable substances appears to be to impart the necessary degree of hardness and strength to enable them to support themselves.

The chemical examination of the earth, is, indeed, full of wonders. The mixture of different soils, for instance, so essential to the production of vegetation, and so universal on the surface of the earth, betrays the wisdom of the Creator. Three earths—lime, alumina (clay), silica (flint), constitute, we have already seen, the great mass of the earth we inhabit, are present in all soils; two of them exist as necessary ingredients in all vegetables. These earths, had chance formed them, or accident thrown them together, would have been found on the earth's surface in great and distinct masses. Mountains of pure alumina would, at least, occasionally have been found by the side of or piled upon masses of pure silex. Strata of pure earths would have been occasionally distinct; the divisions separate and defined; but this is never the case on our globe. The earths are invariably found mixed together, or if a specimen of a pure earth is discovered, its rarity speedily entitles it to a place in the museum of the mineralogist.

Yet, amid all these endless mechanical mixtures of the earths in all soils, the chemist's investigations clearly inform us, that without this mixture no plants could have existed. No vegetable, for instance, will grow in either pure lime, pure alumina, or pure flint; nay, if either earth constitute only nineteen parts out of twenty of any soil, such land is worthless for all the purposes of cultivation. The mixture, therefore, must have been made from the creation, otherwise no vegetable substance could have flourished: no plant would have ripened its seeds.

The advantages of water to all animals and vegetables no one will doubt; the use is universal; the advantages undisputed. It being, then, acknowledged that the presence of a fluid is necessary for our health, and for our very existence, the value of that abounding fluid next engages our attention. The insipidity of water, its utter tastelessness, has often been remarked upon; had it been formed bitter, or sweet, or acid, how nauseating by its incessant recurrence would it have become.

It differs, too, from all other fluids, in being operated upon by the withdrawal of its heat in a manner totally different from all other fluids; other liquids, other solids, are contracted by the withdrawal of their heat; they become solid, they still contract, if their heat is still further withdrawn, but this is not so with water. This all-pervading fluid contracts by the loss of its heat only to a certain point, till it becomes of a temperature equal to about 40° Fahrenheit; it then ceases to contract, and as its temperature is still farther lowered, it begins gradually to expand. Ice is of much less specific gravity than the water of which it is composed. Ice, therefore, which is always of the temperature at or below 32° of Fahrenheit, is hence made to float on the surface of the water, instead of sinking and remaining undissolved at the bottom of the water, which it would have certainly done, had not the Creator, in this case, as in many others, made provision for the foreseen contingency, by making a deviation from the laws by which all other fluids are governed.

(To be continued.)

CHEAP GATTIES FOR A GREENHOUSE.

BEING forced to be economical in my gardening pursuits, I have been trying to keep a cool greenhouse gay with common plants, by making them flower at unusual seasons, and as many of your readers may be in the same position, I may give them the result of two experiments I made last year.

I took a *Lobelia erinus* just about to bloom, in July last,

and cut it over to within an inch of the soil. It started freely, and in November was a mass of blue, in which it remained till the middle of February,—a most valuable acquisition in these dull months.

I had a small plant (a spring cutting) of *Salvia fulgens*, which I kept back with the hope of making it bloom in winter, but, owing to the want of sun, probably, the flowers were abortive, so I gave it little water just to keep it stationary till the end of January, when I gave a shift into a 12-inch pot, and now it is two-and-a-half feet high, and covered with buds, a few of which are in bloom to-day. It will be gorgeous before this is in type.

I do not think the *Salvia splendens* is cultivated as it should be. It is very valuable, blooming, as it does, in winter. Perhaps you or others might recommend other plants suitable for similar treatment. My greenhouse is a "lean-to;" the thermometer during winter 35° to 40° in frost.—G.

[We shall be glad of such suggestions from any of our readers.—Ed. C. G.]

WASPS' NESTS.

QUEEN Wasps are about appearing, and then will be found the nests they establish; and I think it will be of service to inform the readers of THE COTTAGE GARDENER how they may take them (no matter how strong in number, or big in size they may be) without ever being severely stung.

The hot-water system is by no means a safe one; and far less a sure one. It may do occasionally, where a nest is so situated that an abundant supply of boiling water is at hand; but let several nests be situated half a mile off, then it becomes a little more than a joke to get boiling water that distance, and often when applied it harmlessly runs down large cracks in the ground as fast as it can be poured in. Another plan, equally objectionable, is to take a bundle of straw, a pitch-fork, a mattock, candle and lantern, with six or eight in party, and so proceed to the place of conflict, when a portion of straw is lighted and placed over the nest, and more is continually added to keep up the flame; others are labouring at the same time, endeavouring to exhume the nest, which they succeed in doing sometimes, and sometimes not, but it generally terminates with a severe stinging, of which, in bygone years, I have had an ample share; but this mode of proceeding is not at all applicable where nests are situated near a wooden or a thatched building; but many a wounded hedge-row, for years after, could tell the stroller, as he passes, that here the law of warfare had been carried into effect—that is, to kill, burn, and destroy.

The plan I have to propose is simply this: melt any quantity of brimstone in a flower-saucer; have any kind of rags, such as bits of worsted stocking, flannel, or carpet, four or five inches in length, and two inches wide, and dip them well in the melted brimstone. Make enough of these matches, for they will keep any length of time.

The next thing is to find the nest, or nests, which may be unfaulingly done as follows: Suppose the fruit they are attacking should be situated in a confined place between buildings, then take a portion of the fruit and place it in a convenient open space where you can command a clear view; they will soon find it out; take your stand close by, and wait till several cargoes have been taken, carefully marking their line of flight, and if they do not all go in one direction, know for certainty there is more than one nest; then, to find them, go in a straight line according to their line of flight, and, so far as my experience goes, I believe it is an unerring rule to find them. I can now, on some occasions, pretty well determine the distance of a nest in this way: first, suppose the ground inclines downward in their line of flight, and from their starting point they partake of this inclination, you may conclude the nest is between you and the next rising ground. Secondly; if their inclination is the reverse of this, rest assured the nest is beyond the valley lying between you and the rising ground beyond. Having found the nest, take one of the prepared brimstone matches, a lighted lucifer, and spade, and, above all, the house bellows. Then, within a short distance of the nest, light the match at one end, wait a little till it is well lighted, then place the lighted end at the hole, and directly apply

the bellows, blowing the burning brimstone steadily into the nest, pushing the match forward towards the hole as fast as it is being consumed, till the whole is blown into the nest.

At the commencement of this operation a dismal humming noise is heard, but only for a few seconds, when all is hushed in death. No matter how strong the nests are, so much may all be accomplished in two minutes. This being done, dig out the nest, and, if not wanted for any purpose, smash it with the back of the spade, and the work is complete without a sting; for not one will escape to tell the tale.

I hardly need say, this business had better be attended to after dark. If the nests are not dug out the embryo young are not destroyed by the brimstone fumes, and in a few days they become numerous enough to attend to the wants of the colony. I have sometimes taken a nest home, and kept it to watch the young come out of their cells. When the nest is large a very considerable number hatch daily. For many years past, people finding a wasp's nest tell me, as a matter of course; and I, as a matter of course, go and take them. We have had scarcely any here (Hendon) for these two years. Some years they are very numerous. The most in number I ever took in one evening were eight nests. The above method does equally well for hornets.—W. BURGESS, *Hendon, Middlesex.*

BEE KEEPING FOR COTTAGERS.

(Continued from page 491.)

JULY.—Not much can be done this month except keeping the hives shaded and ventilated, removing supers as they fill, and watching for and destroying vermin. Fresh supers should not be given after the second week in this month, or the hives will want a great deal of feeding in October: this chiefly applies to garden counties; in heather counties the season (as already observed) both begins and ends much later.

As supers are removed, the piece of wood, or straw, or, if the weather be hot, the piece of perforated zinc, should be replaced over the centre hole in the stock: in a good season, between twenty and thirty pounds of pure honey may be taken by means of supers: this honey is much better than that from the stocks, both in quantity and colour, and fetches a better price in the market. Early swarms sometimes themselves throw off swarms; these are called virgin swarms, and the honey from them virgin honey: they should always be returned to the parent hive, or joined to a weak stock.

AUGUST.—The directions for last month must be attended to.

m. As the services of the drones are now no longer required, and as their consumption of food is considerable, the bees proceed to eject them from the hives; once out, they soon perish: the numbers lying about frequently alarm the inexperienced bee-keeper, who fancies that a sudden destruction has come upon his hives.

e. Begin to prepare for taking up extra hives: ascertain which of the hives are strongest and healthiest, for these only should be kept. Activity in carrying in pollen, vigorous blowing at the entrance, irritability on tapping at the hive, a sweet and luscious odour issuing from the entrance, resentment of the attacks of strange insects, are all signs of health and strength. Where such signs do not exist, most likely the stock is weak, or the queen has died without leaving a successor; such hives should not be kept, but joined to better hives.

SEPTEMBER, b.—Except in heather counties the honey season will now be over, and the bees will scarcely get enough to keep themselves: all the hives in the Apiary should be weighed, the light ones should be joined on the heavy ones next to them, and those taken up should be safely stowed away or the bees would scent them out and deprive them of their contents.

The position of the pedestals has already been spoken of. Where they are placed in two's, and the space for the third has been filled up, and you have a stock, first swarm, and second swarm together, the two swarms may be joined to the stock, unless the stock be four years old, when it

ought to be taken up: in this case, the stock and second swarm should be joined to the first swarm: but as to this, see Section 5.

If the depriving system has been properly managed, very little will have to be done in joining, except with the stocks which have been allowed to swarm prior to being taken up themselves.

The honey from these old stocks, though dark, and sometimes very much mixed up with brood-bread, is excellent in flavour: the best way of dealing with an old hive will be detailed in Section 6.

m. and c. As the bees become less active, the entrances should be gradually contracted.

(To be continued.)

TO CORRESPONDENTS.

* * We request that no one will write to the departmental writers of THE COTTAGE GARDENER. It gives them unjustifiable trouble and expense. All communications should be addressed "To the Editor of The Cottage Gardener, 2, Amen Corner, Paternoster Row, London."

SPEKELIA FORMOSISSIMA (C. W.).—This correspondent potted a dozen of the old Jacobea Lily, and set them in the warmest end of a greenhouse at the beginning of last November, and is surprised that they have not grown, and asks why this happens? It was ordained at the beginning that this bulb should rest all the winter, and that Tulips and Hæacinths should rest all the summer; and none of us can show that either section has ever been forced to violate the original fiat. They are now beginning to move, and will grow on till stopped by the frost.

ORNAMENTAL GRASSES (R. M.).—All Grasses are highly ornamental, according to some; grasses are among the most useful of the vegetable kingdom, cry others; and, grasses are the most troublesome of weeds, according to a third creed. In short, grasses are anything one likes or dislikes—a vexed question, which Mr. Wheeler, of Gloucester, or Mr. Sutton, of Reading, and the rest of the Grass dealers, are the proper parties to decide. Except *Briza major* and *minor*, we have no grass in the flower-borders, except here and there a patch of *Pompas grass*, and, in old gardens, the Ribbon grass (*Arundo versicolor*).

BERBERIS ASIATICUS (Ibid.).—We do not know where plants of it are on sale. Some one should advertise them, or for them. The seeds ripen in abundance every year.

FLOWER-GARDEN PLAN (Moiru).—The plan and the planting are both good, and will look much better on the ground than on paper. We have made several such alterations on the original, which looked well, but are not so sure of the effect of a duplicate with a leading walk between, but it will be very gay. The original was at Dropmore, and was published in 1827. The two centre figures for Hydrangeas and white Fuchsias are not at all improvements on the original, and the plants for them are not in keeping with that style—they are too high.

HYDRANGEAS (Ibid.).—They will grow in any good garden soil, if it is not chalky, or in peat, or in a mixture of both, and they like very rotten dung. *Deutzia gracilis*, and *Veronica Lindleyana* is not, hardly. *American Groundsel* will flower the first year from seeds; but a bushel of this seed is not worth three farthings, and it is disgraceful to the trade to offer such seeds at all, as not one seed out of five thousand will produce a double flower worth looking at.—D. B.

STOPPING THE LEADER OF FIRS OF SPRUCE (Ibid.).—Stopping the leaders at any height will never cause one of them to get bushy where they are now bare; but it is a good plan to keep them down, and to make them spread on all sides.

CUTTINGS (Carig Cathol.).—Two unsuccessful applications were made on your behalf.

BEES (A Surrey Farmer).—The plan you propose of having your first swarms in "Improved Cottage Hives," and to work these with supers and glasses on the depriving system, is very good, only that your Hives, 13½ in. by 11 in., are a very bad, and to the bees an inconvenient size. *Payne's Hives*, which are 14 in. wide, and 7½ in. deep, inside measure, are far better, and are, indeed, the best-shaped straw hive of the present time.

BEES—UNITING SWARMS (W. G. H.).—It is quite unnecessary to destroy either of the queens when you unite two stocks, or two swarms, or a stock and a swarm. The bees themselves will decide which of the two had better die for the public good.

STEPHANOTIS FLORIBUNDA SEED (Campbell).—The seed-pod is of no use, and it may be a deadly poison. It is not very useful for seeds to ripen here, and some botanist might wish a ripe pod for examination. We are not sure of the time required to ripen it.

GARDEN PLAN (John o' Groat).—We do not recollect the plan alluded to. Your *Strawberries* were not nearly ripe at the end of the autumn. "The worst ones seem to do best," is an index to your complaint; the riper ones are not so green and flourishing as the unripe, and they do better.

LANTANA SELLOWII (A. B.).—If any seedman sent us seeds in the pod, or berry, we would return it instantly, and at his expense. Of course you must rub the clusters of berry-like pods before you sow. The seeds are small, but the chances are that you have no seeds at all, only the seed-pods.

VERBENA-BED AGAINST A WALL (H. G.).—Plant *Robinson's Defiance* at the back for training against the wall, and let the rest of the bed be mixed. But why refer to anybody in a matter of pure and simple fancy?

BEDDING-OUT GERANIUMS IN POTS (C. K.).—There is no rule for the size of pots so used. Small plants in small pots, say No. 48; good-sized plants in No. 32 pots; and larger plants in pots proportionally large. Pots which would do for the plants in the greenhouse will do for them in the beds.

PLANTING TWO BEDS WHERE BULBS ARE (Salon).—Yes; *Mimulus* and *Heurtseuse* may be planted between the Tulips and Narcissus. It is no bad idea. To the second query; No. How could you be so cruel as to kill such beautiful Hepaticas by cutting-off their leaves to make room for seeds. Touch not a leaf of them. We never saw a really blue Polyanthus; a grey violet colour is not uncommon among them, but we never heard of a true blue. Such a self is worth something.

WHITE FEATHERS IN BUFF SHANGHAES AND BLACK POLANDS (Amicus Galli).—A small portion of the primary wing-feathers of the buff and cinnamon Shanghaes is occasionally marked with white; but from the position in which the wing is carried, such markings rarely meet the eye, unless the bird is handled for the examination. As a general rule, any white feathers visible on a buff, cinnamon, or partridge-coloured Shanghae are highly objectionable. The white-crested Black Poland should not have a single white feather, the top-knot alone excepted. In giving this opinion, however, we are fully aware that the presence of white on the tail has not always been held to disqualify, but there appears no reason why the presence of other colours should be any more tolerable in this instance than in Spanish, Black Shanghaes, or Black Bantams. As to the top-knot itself, we have never yet seen an "untrimmed" bird without black feathers at the base above the nostrils.

MARCH AS A HATCHING-TIME (Ibid).—March is a good month for hatching any variety of fowls, though, wherever exhibition at the summer shows is contemplated, an earlier period is chosen. An April-batched bird, however, will probably, by November, be fully equal, in all points, to those that have preceded it in the same year.

MOTHER FOR SILVER-SPANGLED HAMBURGHS (Ibid).—A large Shanghae hen would be too heavy a mother for Silver-spangled Hamburgh chickens, and the latter, being less sturdy and independent in their chickenhood than the former race, would require longer maternal superintendence than the Shanghae dame would probably deign to afford them.—W.

WRITING ON ZINC LABELS (—).—Scrub them bright with coarse sand-paper, and write on them immediately, by the aid of a quill pen, with the following ink:—1 drachm of powdered verdigris (acetate of copper); 1 drachm of powdered sal ammoniac (muriate of ammonia); ½ drachm of lamp black; 10 drachms of water. Mix them together in a two-ounce phial, and shake it every time before using. It is ready for use as soon as the verdigris and sal ammoniac are dissolved.

WEBS ON ROSE-SHOOTS (H. Helyar).—These webs, which draw together the leaves and buds of roses, are formed by the caterpillar of a very small moth, called *Tortrix Bergmanniana* and *Argyrotoza Bergmanniana* by different entomologists. No mode of destroying the caterpillars has been found out, except the tedious one of hand-picking. Try what dipping and stirring the shoots in white Hellebore powder will do. We know of no precautions for preventing the eggs being laid upon the bushes by the moths.

FEATHERS FALLING OFF (J. Brothers).—The feathers falling off as described, we think is only the usual spring moult. Keep the fowls liberally and give them also plenty of green food, and the feathers will return, in all probability, with the warm weather. We do not understand from your note that there are any wounds or ulcers about your fowls.

SILVER HAMBURGH FOWLS (Cold Brafield).—The Spangled are larger and rather harder than the Pencilled. In other respects, we consider them of equal merit. You will see their eggs advertized in our columns.

FOOD FOR YOUNG CHICKENS (B. P. T.).—We have recently given directions for this at p. 431.

BROOD HEN (J. G. B. L.).—It is cruel and ineffectual dipping a hen into cold water to cure her of wishing to sit. She requires a cessation from egg-producing, and ought to have it. If we do not wish such a hen to have chickens, we let her remain on her nest for ten days, and then shut her up for about the same time in an outhouse, without straw. This generally is sufficient for her.

GLASS FOR GREENHOUSE (W. O. D.).—We should use the ribbed glass. *The Cottage Gardener's Dictionary* will give you the guidance you require.

SEA WEEDS (Bessie).—Dr. Harvey's work is an admirable one; the price about seven guineas. The figures are all coloured. Dr. Landsborough's "Popular History of British Sea Weeds" might suit you. Its price is half a guinea. *The Cottage Gardener's Dictionary* is one of the most useful books we know. Its price, 8s. 6d.

FERNS (A. C. Close).—"Can you oblige many of your subscribers by inviting cultivators of Ferns to advertise lists of such plants in your columns. One knows not where to apply." This is from a clerical correspondent, and we know that to advertise Ferns and their prices is very desirable for all parties. There is a growing taste for them.

BLACK MALAYS.—W. Lort, Esq., Great Heath, near Tenbury, would be glad to hear from M. F. G. relative to those birds. Other queries next week.

HARDY BORDER PLANTS (W. Robertson).—Your clever countryman will continue his essays on Evergreens and other hardy border plants.

EGGS JOINED TOGETHER (A. Watts).—Whenever a hen's egg system becomes diseased the phenomena are very various. We never heard before of two soft eggs united together being laid, but we have seen one egg pinched into lengths like links of sausages. Give her a pill of one grain calomel and one-twelfth grain tartar emetic every second day for a week; and give her nothing but soft food, and plenty of green meat. Keep her in a cool dry place.

NAME OF PLANT (Rev. R. M. E.).—The Holly-leaved Berberry, *Berberis aquifolia*, the *Mahonia aquifolia*, as it was called at one time.

LAMENESS IN SHANGHAES (G. S. B.).—It is probable that the lameness in this case arises from an abscess under the dense fibrous structures of the toe. In this case, a free longitudinal incision would afford great and immediate relief, and would readily heal in the course of a few days. It is important that the incision should not be made across the toe, as the tendons might, in that case, be cut across.—W. B. T.

CALENDAR FOR APRIL.

ORCHARD AND FRUIT GARDEN.

APPLES, cleanse from blight; protect blossoms. **APRICOTS**, protect with care. **CHERRIES**, finish training. **CURRENTS**, finish dressing. **DAMSONS** may yet be planted; thin out the crowded spray in the interior. **FIGS**, remove all covering; prune at the end. **GRAFTING**, see that the clay is safe, and rub off wild spray betimes. **GOOSEBERRIES**, beware of the Caterpillar. **INSECTS**, check vigorously early. **MULBERRIES** may be planted. **NECTARINES**, see *Praches*. **PLUMS**, finish pruning those which blossom on the young wood. **PEARS**, as *Plums*; protect blossoms. **PEACHES**, use the cleansing mixture named in former calendars; still protect, and dishud at the end. **PRUNING** of all fruit-trees may still be done, if neglected at proper time. **RASPBERRIES**, get tied if not done; top-dress. **STRAWBERRIES**, spring-dress if delayed. **STAKING**, attend to. **TRAINING**, complete in all fruits. **WALNUTS** may yet be planted. **VINES**, train and plant. *Planting* of all kinds may yet be done, implying, of course, neglect or omission at the best period. But every winter arrear must be brought to a close forthwith.
R. ERINGTON.

FRUIT-FORCING.

AIR-GIVING, attend regularly to, avoiding cold draughts. **BOTTOM-WARMTHS** renew; 75° to 80° are safe points. **CUCUMBERS**, attend closely; stop often; use liquid-manure, and sustain a warm and moist air—70° to 85°. **CILLIES** and the **CAPSICUMS**, pot off and hasted. **CHERRIES**, avoid strong heat; keep a moist air. **FIRES**, moderate, according to season; let solar heat do its work. **FIGS**, such as *Peaches*, as to temperature; water frequently, and pinch young wood. **FLOORS**, wash down frequently. **GRAPE**s, ventilate freely where ripening; remove crowded laterals; succession crops, follow up the usual routine of disbudbing, stopping, training, and thinning. **INSECTS**, exterminate—Aphides by tobacco, Red Spider by sulphur. **KIDNEY BEANS**, apply liquid-manure, and get in successions. **MELONS**, keep thin in bine early, set blossoms, and stop and train weekly; provide successions. **NECTARINES**, as *Peaches*; pinching-off waste or watery shoots, remember. **PEACHES**, train, and top thin fruit. Use the syringe freely, and a free ventilation. Shading use occasionally in case of need. **SPINAGE**, do not lay it by; use it frequently; it is a capital cleanser, and an enemy to insects. **STRAWBERRIES**, attend to daily, water liberally, and give abundance of air, keeping down runners. **TOMATOES**, cool down ready for planting-out in the second week of May. **VINES**, attend well to in the ordinary routine of stopping, training, and berry-thinning; pray do not leave extra berries for a rubbishy tart or two. **WATERING** must be a daily affair now; every thing exauined.
R. ERINGTON.

ORCHID HOUSE.

AIR.—The days are now considerably longer, and the sun has more power, consequently more air will be required to keep the heat moderate. **BASKETS**, continue to renew, if not finished last month; dip them in tepid water once a week; put in baskets plants to ornament the house, such as *Aschmannthus*, *Achimenes*, *Hoju bella*, *Aganympha staminea*, and any other drooping freely-flowering plants. **BLOCKS**, syringe daily. **DENDROBIUMS**, and other plants in flower, remove into a cooler house; they will then last much longer in flower, but as soon as the bloom is over, return them into the warm house to finish their annual growth. **HEAT.**—As the plants will now be growing freely, they require the maximum of heat; in the Indian house, 75° to 90° by day, 65° to 70° by night; the Mexican house should be 10° lower. **INSECTS** will now multiply rapidly; use every means to exterminate them, and prevent their increase. **POTTING**, continue to all such as require it: the grand rule is to pot orchids as soon as new growths are apparent. **SPINAGE** freely in dull weather in the mornings only, but during sunny weather, syringe in the evenings also, shutting up the houses close previously to syringing; a moist growing atmosphere will be the consequence. **WATER.**—As the growths advance, increase the quantity of water at the root; dash it freely upon the platforms, walks, and walls daily, to keep up a large amount of atmospheric moisture.
T. APPLEBY.

PLANT STOVE.

ACHIMENES, re-pot and divide, if required, the first potted batch; specimens may now be made, by placing several plants in a large shallow pot in leaf mould, chopped sphagnum, and turfy loam. **ESCHYNANTHUS**, pot and train to a globular trellis; these make fine showy plants. **AIR**, give freely on all favourable occasions. **AMARYLLISES**, put and plunge in a bark-bed in a pit, to start them into flower and growth. **BARK**, renew, by sifting the old bark, removing the fine particles that pass through the sieve, keeping the rough in the pit, and adding sufficient fresh bark to raise it a little higher than the level; do not plunge the plants till the heat is moderated. **CLIMBERS**, dress, tie, and train neatly. **HEAT.**—Keep up a brisk heat by day, but more moderate during the night. **IXORAS**, attend to specimens of, and tie them out so as to form dense handsome bushes. **MOISTURE**, give to the air of the house by dashing water about upon the floors, walls, and hot-water pipes. **POTTING**, general; finish the first early in the month. **RED SPIDER**, and all other insects, diligently destroy; wash the flues or pipes with water and sulphur mixed together; lay it on with a whitewash brush. **WATER**,

give abundance of to growing plants; keep every part clean and sweet, all decaying leaves remove, and *spring* the leaves of the plants daily, especially as a day's bright sunshine. T. APPELEY.

FLORISTS' FLOWERS.

AURICULAS and POLYANTHUSES will now be advancing fast into bloom; shade from bright sun, and shelter from heavy rains. CARNATIONS and PICOTEES finish potting; shelter from severe weather. CHRYSANTHEMUMS, pot off cuttings put in last month; put in more cuttings, b., keep them in close frames till fresh rooted. CINERARIAS coming into flower remove into the greenhouse; young plants re-pot; smoke frequently to destroy green-fly. CALCEOLARIAS advance a stage by re-potting; smoke these also; frequently the green-fly is their grand enemy. DAHLIAS, pot off cuttings; some that are scarce may yet have cuttings put in; give plenty of air to growing plants; old roots plant in borders towards the end of the month. FUSCIIAS, continue to increase by cuttings, if required; specimens of forms by re-potting twice during the month; re-pot old plants; shake off a large portion of the old soil, and pot them in the same sized pots. HOLLYHOCKS, finish planting, b.; mulch with short litter; sow seed in shallow pans in a gentle heat, or sow in open borders, or nursery beds. MIMULUS, divide, and re-pot in light rich compost. PANSIES may yet be planted in beds; stir the surface of the soil of the beds planted last month. PINKS, cover bed with a thin mulching of very rotten dung, stirring the soil previously; sow seed of either in the open border, or in shallow pans. RANUNCULUSES; if the soil on the surface has become hard, stir it gently, breaking the clods with the fingers; keep a good look out for slugs, if they abound give a good watering with lime water. TULIPS; be very particular, and keep them well sheltered from late spring frosts, but expose them to all the favourable influences of mild rain, and the warm beams of the spring sun. WEEDS, never allow to advance beyond the seed-leaf. T. APPELEY.

FLOWER-GARDEN.

ANNUALS (Tender), prick out those sown in February and March into a hotbed; water gently but often; sow in hotbed; (Hardy) may be sown in borders, &c., to remain; thin those advancing. AURICULAS in bloom, shelter. (See HYACINTHUS.) Supply with water often; those for seed, plunge pots in a sheltered border, where they can have sun until 11 o'clock; plant offsets; propagate by slips; seedlings shade during mid-day. AURICULAS done flowering, place out-of-doors, and separate off-sets. Box edgings may be made, and old taken up, slipped, and re-planted; clip Box edgings. BIENNIALS, finish sowing, b.; plant out those sown last spring. BULBS, in water-glasses, done flowering, plant in ground after cutting down stalks, but not leaves. CARNATIONS, in pots, give liquid-manure every third time, very weak, and water often; stir the earth; sow, e.; plant into borders, b. CLIMBING PLANTS, train and regulate. LAYER RHODODENDRONS and hardy AZALEAS, DAHLIAS, plant to remain, b.; or in pots, to forward in a frame until May. Dress the borders, &c., indefatigably. FRAMES, raise, by supporters at the bottom, as the plants within grow tall. GRASS, mow once a week, and roll oftener; trim edges; dress with earth if poor; and sow seeds, especially white and small yellow CLOVER. GRAVEL, turn and lay afresh in dry weather; roll after rainy weather often. HOEING and RAKING walks give up, and lay them down in concrete. HYACINTHS, shelter from sun by an awning of matting over the beds, from nine to four; give the same shelter in bad weather day and night; cut flower-stalks as they cease blooming, and take special care of leaves. INSECTS, destroy with tobacco smoke, or hellebore powder, or dusting of Scotch snuff. MIGNONETTE, sow in any warm border. MULCH, put round trees newly planted. PINKS, sow, POLYANTHUSES, sow; plant out and propagate by offsets, b.; last year's seedlings now in bloom, mark best for propagating. POTTED PLANTS, give fresh earth to, if not done last month; shift into larger; water freely. PERENNIALS, those sown last spring may still be planted, and propagated by offsets; finish sowing. STICKS are required to blooming plants. TULIPS, shelter from sun and wet; take off pods to strengthen bulbs. WATERING is now required more frequently, yet moderately; give it early in the morning. RANUNCULUSES, water freely, and press the earth very hard between the rows. ROSES, thin buds where very abundant; watch for grubs in the buds, and crush them; make cuttings of *Gloire de Rosanave* to bed next year. TOBACCO WATER, use to destroy the aphides, by dipping the shoots in it where the insects are. Prepare for a large stock of common CAPSICUMS to supersede tobacco for killing insects. Take stock of your BREEDING STUFF, b.; and bring up arrears, if any; keep all such rather dry, and inure to cold in time. D. BEATON.

GREENHOUSE.

AIR, admit freely in mild weather; give sparingly when east winds prevail, and then merely by the top sashes, to avoid cold draughts; shut up early in the afternoon, and if sunny, sprinkle the plants from a fine syringe when it is desirable to encourage growth; plants making their growth should, therefore, if possible, be kept apart from those in bloom. AZALEAS, coming into and in flower, water freely; those to be retarded remove to a north aspect, under glass or even an opaque roof; a temporary protection by mats, canvass, or oiled cloth will answer admirably. BULBS, introduce. CAMELIAS, water freely when in flower; those done flowering keep close, to encourage growth, and shortly afterwards re-pot if necessary. CALCEOLARIAS, CINERARIAS, PRIUROSES, CYTISUS, &c., assist with manure-water, weak, but given often. CACTUS, the late kinds water at the roots, after swelling the stems by syringing. CONSERVATIVE-WALL PLANTS, prune, train, and protect, more to keep off the sun at first than the cold. CUTTINGS, insert; place in hotbed or shady place according to kinds. CLIMBERS, regulate. EPACRIS and HEATHS done flowering, cut back, and also any other *straggling plants*, and keep them by themselves, so as to be close and warm, to encourage them to break freely; those in, and coming into flower, keep in the airiest part. For winter blooming of the reddish-tinted kinds of Epacris, none excels

the *impressa*: *hyacinthiflora* has much larger flowers, but the colour is duller; do not be afraid to cut back such plants freely; and if you can give them a closer atmosphere, and 10° higher temperature than the greenhouse, it will cause them to break better. FUSCIIAS, water the forward ones freely; *fumigale* with tobacco at the first appearance of fly. GERANIUMS, train the first, encourage the second, and stop, pot, and propagate for autumn supply. GENNERA, especially Zebria, and GLOXINIA, various varieties, start in a hotbed; the roots may be kept safely during winter, if dry, in a temperature of from 40° to 45°. This rule applies to the whole of the Achimenes, and most plants with scaly and bulbous tubers. Those who have pits and frames, and no greenhouse, may manage them nicely by packing them in a kitchen cupboard. Few things answer better for window plants in summer and autumn. HEATHS, in bloom and growing, keep in the coolest and airiest part of the greenhouse, and if the sun shines strong, defend the pots by shading or double pots; the *Horea* and *Chorozena* tribes will require similar care, and then, with good drainage and plenty of water, there will be no danger. Prepare for general POTTING by getting soil, pots, &c., in good order, but do not let a plant wait for a time when it wants attention. PROPAGATE by seed, roots, cuttings, inarching, and grafting; young plants thus get strong before winter. Sow SEEDS; beware of burying the smaller ones; the pots should be well watered previously, and when settled, the seeds sown, slightly sprinkled with a little sand, pressed down, and a square of glass or a piece of paper put over the pot; for these, as well as striking cuttings of tender plants, inarching, and grafting, a sweet hotbed would not be desirable. SEEDLINGS, remove as soon as possible from the seed-pans, and prick them out singly, especially if thick. Sow Balsams, Cockscorns, Thunbergias, &c. POT the various *Achimenes*, and introduce tubers for a succession. Remove decayed LEAVES. Stir and loosen the surface soil. SUCCULENTS of all kinds water more freely. WATER for all plants will now be required oftener. MANURE-WATER may now be given more frequently to Pelargoniums that have set their flower-buds, to all plants where vigorous growth is required in pots, and in all cases of plants for vases, beds, &c., where it is desirable, they should be as large as possible by the middle of May. VINES on rafters, train. STRAWBERRIES, set in; even a few on a shelf is a great luxury, and where the vine is scarcely forced, where greenhouse temperature is merely maintained, with a rise from sun heat during the day, the fruit may be obtained a month earlier than in the open air; keep the plants rather dry until the flower trusses show themselves holdy, then water freely. R. FISH.

KITCHEN GARDEN.

Let the head and the hands work together; be on the alert to any sowings that ought to have been performed last month. ALEXANDERS, sow, b. ANGELICA, sow, or plant out autumn sown. ARTICHOKE, plant and dress off. ASPARAGUS, sow or plant; dress off beds, b.; attend that in forcing, water with liquid-manure-water once a week. BALM, plant. BASIL, sow main crop on gentle hotbed. BEANS, plant in succession; attend to earth-stirring the growing crops. BEET, of either kind, sow, m. BORECOLES, sow, and leave for seed. BROCOLI, sow main crops, m.; attend to pricking-out any early sown, and save for seed. BORAGE, sow, and earth-stir autumn sown. BURNET, plant or sow. CABBAGES, sow, plant, or prick out, and earth-stir often. CAUSTICUMS, sow in hotbed, or prick out three plants in each pot, in the seed-leaf, and forward them in hotbed. CARDOONS, sow, e. CARAWAY, sow. CARROTS, sow main crops, m.; attend to thinning early frame or other crops, also to watering in dry weather; this, and frequent earth-stirring, will forward their growth much. CAULIFLOWER, sow, prick, or plant out; attend to earthing-up the hand-glass crops, and assist them with soakings of manure-water. CELERY, sow for late crops, m.; and attend to pricking or planting-out early sown; save for seed. CHAMOMILE, plant. CHIVES, plant. CHERVIL, sow; save for seed. COLEWORTS, plant. CLARY, sow. CRESS (American), sow in succession. CUCUMBERS, sow for hand-glass and other crops; ridge out and attend to those in bearing, as to thinning-out and top-dressing, or earthing-up. DILL, sow or plant. DUNG for hotbeds, prepare. EARTH-STIRRING, particularly attend to in dry weather. FENNEL, old roots divide, and plant or sow. GARLIC, plant, if not done, b. HORSERADISH, plant without delay, HOTBENES for all purposes, attend to. HYSOOP, sow, or plant out old roots. JERUSALEM ARTICHOKE, plant without delay. KALE (SEA), sow, or plant, b.; carefully fork over old beds. KIDNEY BEANS (DWARF), sow, b., where hand-glasses are at command; if not, sow, e.; and *Scarlet Runners*, e. LAVENDER, plant. LEES, sow, b. LETTICES, sow in succession once a fortnight, and plant out; earth-stir among often. MARIGOLD, sow. MARJORAM (*Sweet*), sow main crop on gentle hotbed; (*Common Garden*), plant. MELONS, sow in succession; pot off; ridge out; attend to topping and thinning-out, weekly, the early crops. MUSTARD AND CRESS, sow in succession, where required. MUSHROOM-BEDS, make, and attend to. NASTURTIUMS, sow. ONIONS, sow main crop, b., if not done before. UNDERGROUND or POTATO ONION, plant without delay, also the TREE ONION. PARSLEY, sow of either kind; leave for seed. PARSNIPS, sow without delay. PEAS, sow in succession; attend to sticking, &c.; let them be well basined up before sticking on light soils to aid the watering. PRUNY ROYAL, plant in a cool situation. POTATOES in frames, attend to. RADISHES, sow in succession; attend to thinning young crops. RAPE, sow. RHUBARB, sow or plant; bring forward by inverted pots or tubs over old crowns. RUE, plant. SAVOYS, sow. SALSAFY, sow main crop, e. SCORZONERA and SCRIBETAS, sow, e. SHALLOTS, finish planting, b. SORRELS, plant. SPINACH, sow once a fortnight; thin out; and leave for seed. TANSY and TARRAGON, plant. TOMATOES, sow in hotbed, and prick out in pots, and forward in hotbed. THYME, divide old roots, and plant out. TURNIPS, sow, b. and e.; leave for seed. VEGETABLE MARROW, sow in hotbed. WORMWOOD, plant. T. WEAVER.

THE BRITISH ECONOMICAL MANURE COMPANY supplies in any quantity THE "ECONOMICAL MANURE," a complete and by far the cheapest substitute for Guano.

12 to 14 cwt. per acre of this powerful Manure costing 15s. to 18s., is ample (more must not be used), and equals 3 cwt. of the best Peruvian Guano, thus saving at least 50 per cent., besides carriage, &c.

The agricultural world is respectfully urged to read the hundreds of Testimonials from all parts of ENGLAND, SCOTLAND, and WALES, FRANCE, BELGIUM, and SPAIN, to be convinced that this Manure warrants especial and immediate attention. They prove that it gave most wonderful results last year on every soil and crop, far surpassing the expectations of the purchasers, the dampness of this climate and the coldness of the soil peculiarly favouring its action on the vegetation.

No one reading the Company's pamphlet can doubt its being by far the cheapest of all Manures. In fair comparative trials on every kind of soil and crop with guano, dung, and other long recognised fertilizers, it will be seen the "ECONOMICAL" was superior, that it proved most valuable for fruit-trees, shrubs, and garden purposes, and produced the most astonishing effects upon manure-heaps, applied in solution, decomposing in fifteen days all vegetable matter, peat included, and that it is a perfect deodoriser for liquid manure, besides enhancing its fertilizing properties.

It is the result of many years labour of an eminent Foreign Agriculturist, the Director of the Government Schools of Agriculture in his own country, and of high reputation as a chemist. It is patented, and is one of the most useful and greatest discoveries of the day.

Price 12s. per cwt., packages included, and delivered free on rail or wharf in London.

The Company's pamphlet containing the Testimonials, directions for use, and all particulars, also samples, to be had at the Offices, No. 10, Mark Lane, Lane, London, or sent on applying to

BENJAMIN COVENEY, Manager.

Good Agents wanted. An allowance to the trade.

MANURES.—At a time when one of the farmer's greatest needs is a want of Manure, we think we shall be doing nothing more than our duty in calling his attention to where he may look for a supply. It would be a step in the right direction to make himself more or less independent of those who appear so little inclined to accommodate him. With this view he might surely test the wares of others more anxious to have his support. In another column will be found the prospectus of the British Economical Manure Company; an undertaking that appears already to have obtained some position, and that has the names of many well-known agriculturists ready to speak to the merits of the article it supplies.—*Mark Lane Express*,—20th February.

ATKINSON & BARKER'S ROYAL INFANT'S PRESERVATIVE.—MOTHERS, call at your Druggist's, or our Agents, and purchase a bottle of the above. IT IS THE BEST MEDICINE IN THE WORLD FOR INFANTS AND YOUNG CHILDREN for the prevention and cure of those DISORDERS incident to INFANTS; affording INSTANT RELIEF IN CONVULSIONS, Flatulency, Affections of the Bowels, DIFFICULT TEETHING, &c., &c., and may be given with safety immediately after birth. It is no misnomer Cordial!—no stupefactive deadly narcotic! but a veritable preservative of Infants! Mothers would act wisely in always keeping it in the nursery.

Prepared only by ROBERT BARKER, Bowdon, near Manchester (CHEMIST TO HER MOST GRACIOUS MAJESTY QUEEN VICTORIA), in Bottles at 1s 1/2d, 2s 6d, and 4s 6d each.

CAUTION!—Observe the names of "ATKINSON & BARKER" on the Government stamp.—Established in the Year 1793.

FRUIT TREES, POULTRY, RABBIT, SHEEP, AND CAT FENCING.—Worsted Netting to protect the Bloom of Peach, Nectarine, and other Trees, Flower, or Seed Beds, from Frost, Hight, and Birds, 2 yards wide, 5d per yard. NEW TWINE NETTING, (Tanned if required). One yard wide, 14d per yard; Two yards wide, 3d per yard; four yards wide, 6d; Half-inch Mesh ditto 2 yards wide 6d per yard. TANNED NETTING, two or three yards wide, 1 1/2 per yard; Four or six yards wide, 3d per yard, or 5s per 100 yards, one yard; 10s per 100 yards, two yards; and 20s per 100 yards, four yards wide. ELASTIC HEXAGON GARDEN NET, or Serim Canvas, 4 1/2 per square yard. COCOA NUT FIBER, or Hemp Sheep-riding Net, of superior quality, four feet high, 4d. to 6d. per yard. Rabbit Net, four feet wide, 1 1/2; six feet wide, 2 1/2; eight feet, 3d per yard. Each Edge Corded, 1 1/2 per yard extra, suitable for Poultry Fencing. Square Mesh Cricketing Net, fix 3/8 full width and length, made of stout cord, 3d to 4d per square yard; this is the best article made for fencing, against fowls, cats, &c.

At W. CULLINGFORD'S, 1, Edmund Terrace, Balls Pond Road, Islington, London. Orders by Post, with Post Office Order or Town reference, punctually attended to. The Trade supplied. Fishing Nets of all kinds in stock. Nets made to order. Tents, Marquees, Rick Cloths, Tarpaulin, Lines, Rope, Twine, &c. made to order.

SCYTHES.—BOYD'S PATENT SELF-ADJUSTING SCYTHE will last out three of the ordinary sort, and is always ready for use. "We have seen this scythe at work, and can strongly recommend it."—See *Mark-lane Express*, May 16, 1853. To be had of every Ironmonger and Nurseryman in the kingdom, and wholesale and retail of WM. DRAY and Co., Agricultural Implement Makers, Swan-lane, London.

HORTICULTURAL BUILDING AND HEATING BY HOT WATER. Warranted best Materials and Workmanship, at the lowest possible prices.

J. WEEKS & Co., King's Road, Chelsea, Horticultural Architects, Hothouse Builders, and Hot-water Apparatus Manufacturers. The Nobility and Gentry about to erect Horticultural Buildings, or the Hot-water Apparatus, will find at our Hothouse Works, King's Road, Chelsea, an extensive variety of Hothouses, Greenhouses, Conservatories, Pits, &c., erected, and in full operation, combining all modern improvements, so that a lady or gentleman can select the description of House best adapted for every required purpose. The Hot-water Apparatus (which are efficient and economical), are particularly worthy of attention, and are erected in all the Houses, Pits, &c., for both Top and Bottom Heat, and in constant operation in the Stoves. The splendid collection of Stoves and Greenhouse Plants are in the highest state of cultivation, and for sale at very low prices. Also, a fine collection of strong Grape Vines in pots from eyes, all the best sorts, Plans, Models, and Estimates of Horticultural Buildings; also, Catalogues of Plants, Vines, Seeds, &c., forwarded on application.

J. WEEKS & Co., King's Road Chelsea, London.

ALLSOPP'S PALE or BITTER ALE.—Messrs. S. ALLSOPP and SONS beg to inform the TRADE that they are now registering orders for the March Brewings of their PALE ALE in Casks of 18 Gallons and upwards, at the BREWERY, Burton-on-Trent; and at the under-mentioned Branch Establishments:—

- LONDON, at 61, King William-street, City;
- LIVERPOOL, at Cook-street;
- MANCHESTER, at Ducie-place;
- DUDLEY, at the Burnt Tree;
- GLASGOW, at 115, St. Vincent-street
- DUBLIN, at 1, Crampton-quay;
- BIRMINGHAM, at Market Hall;
- SOUTH WALES, at 13 King-street, Bristol.

Messrs. ALLSOPP and SONS take the opportunity of announcing to PRIVATE FAMILIES that their ALES, so strongly recommended by the medical profession, may be procured in DRAUGHT and BOTTLES GENUINE from all the most RESPECTABLE LICENSED VICTUALLERS, on "ALLSOPP'S PALE ALE" being specially asked for.

When in bottle, the genuineness of the label can be ascertained by it having "ALLSOPP and SONS" written across it.

BAKER'S POULTRY RESTORATIVE.—A Certain Cure for all Diseases of Poultry, Pheasants, &c., and most especially valuable as a Preventative, for imparting vigour and high condition.

Messrs. B. recommend it with great confidence, as they have themselves used it for many years with the greatest success. The Restorative is in a Liquid and in Pills, and one amongst its numerous advantages is the simple manner in which it is administered, and will be found invaluable to all breeders and keepers of Poultry.

The Pills and Bottles 2s 6d each, with full directions. S. C. & C. N. BAKER, Half-Moon Passage, Gracechurch Street.

GLENFIELD PATENT STARCH, used in the Royal Laundry; Wotherspoon's Machine-made Lozenges and Comfits, packed in neat 4 oz., 8 oz., 16 oz., and 7 lb. Boxes, free from colouring matter, which is so much objected to; Scotch Marmalade, Jams and Jellies, now so universally known for fine quality, prepared by Steam Power, for Home use and Exportation. Sold by all Shopkeepers. London—WOTHERSPOON, MACKAY, & Co., 66, Queen Street, Chapside.

Glasgow—ROBERT WOTHERSPOON and Co., 40, Dunlop Street.

FOOD FOR PIGS.—Rice Meal is now acknowledged to be the best and cheapest Food for Pigs. It is now being extensively used by the largest Pig-feeders in the kingdom, to whom reference can be given, as also to several who won prizes at the last Smithfield Cattle Show. In order that small consumers may test its merits, 4 cwt. will be sent for Post Office Order of £2 2s, including sacks. Rice Meal, £0 per ton.

JAMES MAY and CO., Finsbury Wharf, City Road Basin, London. Delivered in London Free.

THE ROSE GARDEN, By WILLIAM PAUL, of the Nurseries, Cheshunt, Herts. "Infinitely the best work ever written on the Culture of the Rose."—*Botanic Garden.*

By the same Author, price 1s. **AN HOUR WITH THE HOLLYHOCK.** London: PIPER BROTHERS & Co., 27, Paternoster Row; and all Booksellers. New Edition, Price 8d; or by Post, of the Author, Kelsale, Saxmundham, Suffolk, 1s.
